I believe that the proportion of children with discharging ears, all of whom are liable to acquire mastoiditis, is far less than formerly, chiefly because we pay more attention to prophylaxis. I need not remind my readers that every ear infection takes place through the Eustachian tube—that an infected nasopharynx is responsible for many of the troubles of childhood. The wholesale removal of tonsils and adenoids may result in certain evils, but these are discounted by the vast benefits. At the New York Eye and Ear Infirmary, we operate upon about 1,500 children for abnormal tonsils and adenoids a year, mainly with beneficial results. We frequently cure discharging ears in this way; we often prevent ear discharges.

*Read before the Dutchess-Putnam County Medical Society, at Lake Mahopac, N. Y., July 12, 1916.

SYMPTOMS.

The symptoms of acute mastoiditis in childhood and in adult life differ considerably. In the former case, we cannot rely on subjective symptoms; in the latter, they mean a great deal.

Children. Frequently, the infant or child suffers acute pain in the ear. Examination shows a bulging drum which either ruptures spontaneously, or preferably is incised. An incision should be performed under proper illumination and should start at the upper posterior quadrant, going downward and forward. The next thing to be noted is the discharge from the ear, which at first is serous, but within twenty-four to forty-eight hours becomes purulent. At this time the child may be showing a high temperature, which in itself is not alarming, but if fever continues after forty-eight hours, we must watch carefully.

After the initial incision, the child may no longer complain of pain. He should be put to bed, the ear irrigated, and proper attention paid to the nasopharynx. If the temperature continues high and other conditions are eliminated, we must suspect an involvement of the mastoid.

It is my custom, in observing such cases, to depend mainly on objective signs. Daily examination reveals changes in the character of the discharge. Examination of the drum shows how much tension is behind it, and whether there is any sagging of the posterosuperior wall—a pathognomonic sign. We examine for edema over the mastoid process itself, and attempt to find definite tenderness, which is frequently difficult in little children. If the discharge does not clear up at the end of a week or ten days, some otologists assert that it is best to operate upon the mastoid, rather than run the risk of a complication or a possible deafness. I believe that this is overstepping the mark and that many children recover from a mastoiditis spontaneously, even when the discharge has lasted for weeks or months. Such children are perfectly safe if they can be carefully watched day by day.

Of course, where it is possible, every aid for the determination of the severity of the infection should be employed. Examination of the blood should be made frequently to determine the total leucocytosis and the relative number of polynuclear cells. A culture of the discharge from the ear will determine the invading organism and tell whether we are safe in allowing the condition to continue. For example, Staphylococcus aureus infection gives little cause for alarm; on the contrary, an infection caused by Streptococcus mucosus capsulatus makes early operation imperative.

In infants and very young children, where the symptoms are very mild, I believe we are safe in waiting until a subperiosteal abscess forms. Fortunately the mastoid process is not well developed early in life, and the bone separating an infected area is thicker around vital parts than it is near the cortex. The result is that as the infection extends, the first destruction of surrounding bone is in the cortex. The pus ruptures through and forms an abscess underneath the periosteum. To illustrate how little danger there is in waiting in such cases, let me cite the following example:

Case I. About two months ago I was called in consultation to see a boy of twelve years who had a severe pain in the right ear. A year before he had had a mastoidectomy performed on the left side.

Examination showed a bulging drum, which was incised. A profuse discharge of seropus began immediately. In view of the fact that the mastoiditis had developed rapidly when he had had trouble with the other ear, my prognosis was guarded. The following night, the temperature still remaining high, I was asked to see him. Tenderness had developed over the mastoid. I requested the pediatrist on the case to let me know how the boy got along, and definitely stated that I expected the case to come to operation. For two weeks I heard nothing. Then I was called upon to see another member of the family. I noticed the boy's ear sticking out from his head. Definite edema was present. Before arrangements could be made for the operation, the abscess had perforated behind the steromastoid muscle into the neck. A simple mastoidectomy was performed with counterdrainage into the neck. At the end of two weeks the wound had healed, and the boy made an uninterrupted recovery.

In some instances children present practically no symptoms. Where persistent discharge continues over weeks, we must depend on objective findings. These are the cases that lead to sinus thrombosis, brain abscess, or meningitis. What is of equal importance in the long run is loss of hearing that results from continuous discharge, a loss due to adhesions in the middle ear and destruction of the drum. If it is possible to ascertain that the child is losing his hearing, I believe that surgical procedure is more sensible than conservatism. We must examine the drum daily, noting the amount of discharge, the pulsation of the drum, the amount of bulging, and evidences of narrowing of the canal. In order to show how obscure the symptoms may be in a definite case of mastoiditis, let me cite the following case:

Case II. A boy of five years was referred to me in December. He complained to me of a pain in his ear, and had a slight fever. Examination showed a bulging drum, which I incised that evening. A discharge of serum occurred, changing to pus within twenty-four hours. For two weeks, the child seemed perfectly well, except that the discharge continued, and he had fever up to 100° F. every night. There was slight tenderness over the antrum, but nothing of a definite nature to worry over. After these indefinite symptoms had continued for about four weeks, I was convinced that a mastoid operation was necessary because the hearing was getting worse day by day. I insisted on a consultation with another otologist, who firmly declared that we were perfectly safe in waiting. Today we have the x ray at our command, and if a picture can be taken properly, we are able to compare the pictures of the two mastoids, and in many instances can state definitely whether a diseased process is present. Such pictures are hard to take in children, but, in this case, we were able to get an excellent picture. I asked the consultant if he would not operate if the x ray showed a pathological condition. He agreed that he would. The x ray picture showed a total destruction of the mastoid. I operated immediately, finding exactly the condition I suspected—total destruction of the mastoid. The boy made an uneventful recovery.

Symptoms in adults.—The symptoms of acute mastoiditis often differ materially in adults from those in childhood. There are two classes of cases—the acute fulminating type, and the latent type.

Fulminating cases.—It is impossible to tell in any given case how rapidly symptoms may occur, or how rapidly they may subside. The average practitioner is not in a position to take advantage of all the new tests we have in large hospitals devoted to this special work. He will have to depend mainly on the symptoms the patient complains of, and the signs elicited by proper examination. We shall outline the main symptoms briefly:

Pain. There is usually a deep seated pain in the ear due to the inflammation in the tympanic cavity. As the invasion of the mastoid continues, pain is often complained of over the mastoid itself, first in the region of the antrum, and then over the tip. Many patients complain of radiating headache, which extends from the supraorbital region to the occiput—a hemicrania.

Discharge. The discharge, purulent or mucopurulent, is very profuse. A piece of cotton placed in the ear canal, will become saturated in from five to ten minutes. The character of the discharge, particularly the determination of the invading organism, will often aid in determining the severity of the infection. Discovery of Streptococcus mucosus capsulatus, an organism that destroys bone rapidly, an organism which is responsible for many mastoid complications, makes immediate operation imperative. Next in order of importance are Streptococcus pyogenes aureus, the pneumococcus, and the staphylococcus. The latter is seldom responsible for the fulminating type of mastoiditis.

Tenderness. Although tenderness is nearly always present in cases where the mastoid is infected, we must remember that tenderness is frequently present over this region in cases of acute otitis media with an inflammatory condition of the mastoid mucosa. I have seen many cases end in recovery without operation, where the tenderness over the mastoid was extreme. A number of years ago I had six members of one family with acute otitis media. Three of them had extreme tenderness over the mastoid, and I insisted upon operation. Two of them refused operation, and got well without surgical interference. The other also recovered after operation, but had a prolonged convalescence due to a complicating erysipelas.

There are two kinds of tenderness—superficial and deep. The former is ascertained by light pressure with the thumb over the mastoid. Deep tenderness is determined by deep pressure, particularly over the antrum or tip. The chief point to be considered is whether the tenderness spreads day by day. If it is apparent that tenderness is present over the antrum and tip, and then spreads posteriorly, we must suspect a gradually invading process which can be cured only by operation.

High temperature. This symptom means little in adults. As a rule, in the fulminating types, the temperature may rise to 103° F. or higher, but lack of fever is no indication of a recovering process. Some of the worst cases I have seen have been those with no fever at all, or with a rectal temperature remaining well under 101° F. Fever associated with chill makes us suspect a complicating lesion, i. e., infection of the sigmoid sinus.

Deafness. On account of the profuse discharge and inflammation, deafness is a frequent symptom. In itself, it means nothing, for if the ear is properly attended to the deafness is seldom permanent. However, taken in conjunction with other symptoms, it may indicate the extent of the inflammation in the middle ear.

Objective findings. The examination of the mem-

brana tympani and surrounding parts is of the greatest importance. After wiping the canal clean we note the amount of pulsation of the drum, the quantity of discharge, the size of the opening in the drum, the rapidity with which the discharge comes through the incision, and particularly if there is any sagging of the posterior wall and Schrapnell's membrane. The sagging of the posterior wall indicates that there is pus in the antrum and mastoid which is trying to escape. We err on the side of safety, if we operate early in fulminating cases. Wherever possible, I take such patients to the hospital and have an x ray picture taken. In fact the x ray picture is the best consultant we can have in such cases.

I hesitate to operate before the fourth day in any case of mastoiditis, unless the indications are clearly outlined. We may carry out conservatism too far, as will be noted in the following case:

Case III. In January, I was asked to see a doctor's wife, sixty-three years old, who had had grippe for two weeks. The ear drum was bulging. I opened it up immediately. I watched her for two days, during which time she complained of pain in the ear, headache, and had a temperature as high as 103° F. On the third day, a culture of the discharge showed a capsulatus infection. The blood count was 17,500, with eighty-five per cent. polynuclear cells. I advised a consultation. Immediate operation was decided upon, although such early operation was contrary to my usual custom. On opening up the mastoid, the cells were found full of pus, although there was no breaking down of the interstices between the cells. A complete exenteration was done.

The following day the temperature rose to 105° F. and remained there for two days. The presence of meningitis was eliminated, pneumonia and pyelitis were ruled out. Then the wound was reopened. On exposing the dura, a latent brain abscess was discovered, which apparently had ruptured at the time of operation. The patient died three days after operation.

In another case presenting similar symptoms, I watched carefully for three days, at the end of which time I had an x ray picture taken, which showed cloudiness of the mastoid. I informed the patient that within the next twenty-four hours he would have to be operated upon. Before this time had elapsed his temperature began to come down, and two days later he left the hospital perfectly well.

Latent mastoiditis. A few years ago I described in the *American Journal of Surgery* a series of cases under the caption Latent Mastoiditis, in which the symptoms passed from the acute to the quiescent stage. The temperature had returned to normal, the general feeling of malaise had disappeared, there was no longer any headache, and there was no pain. Sometimes pressure over the mastoid would elicit tenderness, at other times not. All that the patient complained of was the continuous profuse discharge from the ear, and almost total deafness.

I consider these cases among the most difficult and dangerous with which we have to deal. For the subsidence of symptoms frequently means that the trabeculæ between the mastoid cells have broken down and that a large abscess cavity is present which is draining through incision in the ear drum. In a minority of cases Nature performs a mastoid exenteration without outside interference. But the process may extend through the protective barriers, which separate the mastod cavity from vital parts, with the result that a sinus thrombosis, or brain abscess, develops. Because the disease is working insidiously, we should be on the lookout.

The careful otologist observes in these cases that the canal is very much narrowed, the drum extremely thickened, and that the discharge of pus is very thick and creamy. I have watched such cases for four to six weeks, realizing that the patient stood little chance of getting well without operation, yet hoping that the patient's natural resistance would be stronger than the local infection. At last the time comes, however, when conservatism has been given a fair test, and when the patient is up against the alternative of having a simple mastoid exenteration performed, or else taking the responsibility of waiting into his own hands. We must realize that these patients are not very ill. It is hard for them to understand that after having gone through much suffering, and after having overcome the severe symptoms, they should have to undergo a severe operation when they are feeling much better.

During the past year I had a number of such cases. In one instance, a young girl had had a discharge from her ear for six weeks. When operated upon a perisinus abscess had formed, which at any moment might have invaded the jugular vein, resulting in a streptococcemia. In another case, the patient presented absolutely no symptoms, yet, at the end of four weeks, when an x ray picture was taken, the whole mastoid was found destroyed. In two cases in which I took x ray pictures, the mastoiditis had continued for six weeks, after the acute symptoms had disappeared. We can readily see the impossibility of either of these cases proceeding to recovery without operation.

DIAGNOSIS.

If we take into consideration the symptoms enumerated above, there is little difficulty in making a diagnosis of mastoiditis. In fact, there is seldom as much difficulty in making the diagnosis as in determining the proper time to operate. We ought to be conservative in all ear cases, but we must not carry our conservatism to the danger point. The character and amount of discharge, the general symptoms of the patient, such as fever, malaise, headache, etc., the amount and character of the pain, the site of the tenderness, the blood examination, the objective signs to be noted in the ear—all are factors of importance. A proper x ray picture, the importance of which I brought out in a paper on that subject in the New York Medical Journal for June 10, 1916, gives an exact idea of the amount of invasion of the mastoid cavity.

PROGNOSIS.

In all cases that are properly operated in, we should have little fear of ultimate disaster. I believe that our mortality at the New York Eye and Ear Infirmary is less than one per cent.—a mortality little more than that from appendicitis. Of course, we must realize that in such an institution, devoted to such special work, the results are better than in general hospitals where but few cases are seen. But this again is negatived by the fact that we get the severe cases here as well as the simple ones.

No one fears mastoiditis, but we do fear the complications. Yet it is surprising that in many cases where the dura is exposed, or the sinus is uncapped, there are very few complications in propor-

tion to the number of cases seen. Among the complications which make the prognosis bad are:

1. *Sinus thrombosis.* This is due to an invasion of the sigmoid sinus by the infecting organism. A high intermittent temperature, associated with chill, with a positive blood culture, clinches the diagnosis. The complication is relieved by resecting the jugular vein and clearing out the sinus. I have had two patients who had this complication, both of whom recovered after jugular resection.

2. *Brain abscess.* Such an infection may occur by direct infection of the dura, through the diploic veins or through the lymphatics. The symptoms are often obscure and the prognosis bad. I will cite one example:

Case IV. About two years ago, a young woman was admitted to our service at the City Hospital on Blackwell's Island, suffering from acute mastoiditis, with an associated abscess of the scalp extending to the median line, and forward to the supraorbital region. The infection was an unusual one, due to Bacillus coli communis. On operation, a perforation of the posterior canal wall was found, leading into the mastoid bone. The middle ear cavity was not infected. Operation was performed immediately. During the following days, the patient had little fever, but complained of extreme headache and was delirious much of the time. Blood examination revealed nothing. Examination of the spinal fluid was negative. The ophthalmologist pronounced the eye grounds negative and found no choked disc. The neurologist went over the patient and pronounced the case one of hysteria. The following day the patient died. Post mortem examination showed a temporosphenoidal abscess as large as a walnut, which could be traced directly to the original mastoid infection.

3. *Meningitis.* This is a rare complication. It is usually due to a direct extension of a virulent organism.

4. *Facial paralysis.* The facial nerve runs an irregular course through the mastoid bone. Unfortunately, it may be injured at the time of operation.

5. *Erysipelas.* This winter I was unfortunate enough to have three of my patients acquire erysipelas, after being operated upon for mastoiditis. This disease spreads very rapidly in an ear hospital, for what reason we do not know. The complication is alarming to the patient, but is seldom serious, particularly now that we can depend upon the Hiss leucocyte extract. This extract is obtained from rabbits and may be injected in the gluteal region in ten c. c. doses, once or twice a day until fifty to sixty c. c. are given. It is almost a specific in erysipelas. I am at present working on a new treatment for erysipelas at Bellevue Hospital, which I will report at a later date.

TREATMENT.

I shall spend little space on the treatment of mastoiditis. It is mainly operative. The operation is extremely technical, and should be undertaken only by the trained otologist. Some years ago, I described a primary suture of the mastoid wound, which facilitates healing remarkably. I believe Nature can help the surgeon a great deal, if the surgeon is willing to let Nature cooperate. There is no longer any need for painful packings and a wide open wound. After we are assured that the operation has removed all infected bone, a wick of gauze is placed in the antrum and allowed to come out of the lower end of the wound. The wound is closed. At the end of thirty-six hours, the gauze is removed. The lowest portion of the incision is kept open for ten to twelve days by daily probing. The wound is massaged daily. At the end of twelve days to two weeks, as a rule, my patients are completely cured.

Let me hope that this little résumé will give my readers some practical points which will help them to take proper care of patients who suffer from acute mastoiditis.

SHALL WE GET RID OF TUBERCULOSIS AT LAST?

By Richard Cole Newton, M. D.,
Montclair, N. J.

Ex-President New Jersey State Board of Health; Consulting Physician, Mountainside Hospital.

The so called pretuberculous stage, according to our present information, is a misnomer. It is now acknowledged that the dyspepsia, the nervousness, the palpitation of the heart, the pallor, the emaciation, the want of appetite, the subnormal temperature, the broken and unrefreshing sleep, the lack of energy, and the depression of spirits which precede the distinct manifestation of the disease, are not signs of oncoming tuberculosis, but are due to the disease itself, already present and active in the body.

We can never hope to conquer any disease until we know its life history, as well as its cause. Our present comparative helplessness in the matter of cancer is presumably because we do not yet know its real cause; whereas, having found the cause of typhoid fever, and having known its mode of action for years, we have in vaccination an efficient preventive against the infection. In tuberculosis we have been acquainted with the infecting agent since Koch's great discovery of the tubercle bacillus in 1882, and we formerly believed that this great man had also discovered the remedy when, in 1890, he announced that hypodermic injections of tuberculin would cure tuberculosis.

The whole world went tuberculin mad. Every one hastened to do honor to Koch and to employ his remedy; only to find that there had been a great mistake made somewhere and that the results of the disease had not been greatly improved by the new treatment, although its exciting cause had been demonstrated, and Professor Koch, who possessed one of the few really great medical minds known to history, had declared that he had found the remedy. Men not yet old can recall the all but universal prevalence of the "tuberculin delirium" that followed the announcement of the new remedy. High and low, rich and poor, learned and ignorant, lay and professional, all united in the joyful belief that at last the "great white plague" had been conquered. Koch and his followers, however, made the mistake of assuming that a few injections of tuberculin would cure the disease, and they gave far too large doses and at too short intervals, so that the orderly working of the forces of the body, which were doing everything that they could to repel the invading army of tubercle bacilli, were thrown into disorder and, instead of fighting the invader, began fighting among themselves.

It was in 1890 that Koch announced the discovery of a cure for tuberculosis, which an encyclopædia informs us, "has not been supported by further experience." There was then living one of the world's greatest scientists, to whom we owe a debt for the advancement of medical knowledge that can never be repaid. His name was Virchow. He died in 1892. One of the last acts of his long and busy life was to lead a crusade against the new remedy for tuberculosis. He alleged that it "mobilized" the tubercle bacilli already present in the patient's system, and drove them all over his body to carry on their work of destruction.

It was not generally known then, but we know now, that in scientific matters Professor Virchow had become a reactionary. He never accepted the Darwinian theory. In short, his mind had crystallized. No sudden recoveries, however, from tuberculosis had followed Koch's treatment, like those which had followed von Behring's antitoxin in diphtheria. Inasmuch as from the overdosing of the tuberculous patients with tuberculin, already alluded to, the condition of the latter had apparently, if not actually, been made worse, most physicians were quite ready to accept Virchow's dictum and condemn tuberculin out of hand. They vilified the remedy and its inventor with almost as much vigor as they had extolled them at first. The disappointment was bitter and lasting.

Now, after nearly thirty years, we are about to see a tuberculin renascence. It is to be most devoutly hoped that we shall see no return of the "tuberculin delirium." Most probably we shall not. For where it has taken nearly a generation to try out and prove carefully the effects of a remedy, its unreflecting, uproarious adoption is quite unlikely.

It has fought its way back into favor in spite of the antagonism or at least the indifference of the profession and the laity. Doctor Baas, in his celebrated *History of Medicine,* has repeatedly warned us that whatever has been quickly and universally adopted in medicine has almost universally turned out to be valueless; and this is easily explained, at least so far as tuberculosis is concerned, because it is an exceedingly difficult remedy to use correctly, and its results are, generally speaking, only gradually and slowly achieved. There is nothing pyrotechnical or cyclonic in its action. Properly administered it is a reinforcement of the natural forces of the body at the proper time and in the proper manner, so that the *vis medicatrix naturæ* may conquer and drive out the invading forces of the disease.

As we now know, tuberculosis is usually a lifelong disease. It is acquired in most cases before puberty, in many instances in infancy, so much so that seven young people out of ten have been infected with the tubercle bacilli before they are seventeen years old. Fortunately, out of this number, probably seven eighths are strong enough to conquer the disease without treatment, so that it will never become really active in their systems. This slow development of the infection, and the great resisting power of our bodies, show conclusively that a little help at just the right time will enable practically everybody to rid himself of tuberculosis.

A teacher in the Polyclinic Medical School and Hospital of New York[1] has solved the problem which baffled the great Professor Koch and many of his followers, namely, how to administer tuberculin safely, easily, and effectively. This expert does not put his patients to bed. He does not send them to sanatoriums. He does not stop their ordinary occupations or mode of life. He just has them come to him twice a week and injects a little, a very little bit of Koch's tuberculin under the skin of their arms, and increases his dose very, very slowly, so that he finally produces a state of immunity in their bodies against the infection of the tubercle bacilli, and the patients are well almost without realizing in what desperate danger they have been.

You may ask how does the doctor find out that these people have tuberculosis in the very early stages of the disease? The answer is, that he tests them with doses of the tuberculin, just as cattle are tested, to find out if they "react," that is, have a certain rise of temperature at a certain time after the injection of the tuberculin. If they react, treatment is instituted promptly, but with great caution and careful observation, so that no unnecessary inconvenience results. The patients keep right on at their work. Their families, if they have any, are not deprived of their support. There is no going away from home to spend long, desolate hours in a sanatorium.

Naturally thousands of people can be treated by this method where only dozens can go to sanatoriums, and verily that golden moment is in sight which was predicted by Professor Koch when he said, in referring to the early treatment of all cases of tuberculosis, "only then will the new method have become a genuine blessing for suffering mankind, when it will have come to pass that all cases of tuberculosis are taken early under treatment and the occurrence prevented of advanced, neglected cases which up to the present have formed the inexhaustible source of ever recurring infection."

THE STRUGGLE FOR BINOCULAR SINGLE VISION.

By Aaron Brav, M. D.,
Philadelphia,
Visiting Ophthalmologist, Jewish Hospital; Ophthalmic Surgeon, Lebanon Hospital.

By binocular single vision we understand that visual phenomenon that enables us to see objects single, although both eyes take part in the visual act. It is not uncommon to hear patients complaining of double vision. Of course this is observed only in abnormal cases, where there is a disturbance in the equilibrium of the external muscles of the eyes, but it suffices to lead us to the conclusion that there must be some essential factors in normal eyes that prevent this annoying condition. If we had only one eye, double vision would practically be impossible, except perhaps in hysteria and in cases with a double pupillary opening. But the visual organ in man is a highly complex apparatus, in which two eyes perform the same function simultaneously, each eye perceiving

the same impression of the same image. This would give rise to double images, were it not for a special mechanism, whose object it is to fuse the two images into one percept, that is constantly at work in the effort to maintain binocular single vision. Binocular single vision is determined by a process of fusion. In normal eyes this fusion is accomplished without much difficulty, but in abnormal eyes this effort to fuse two images into one distinct percept is accomplished only by a very hard struggle of the mechanism, and often in this struggle the mechanism is unable to overcome the obstacle and double vision is the result.

Absence of double vision does not necessarily mean binocular single vision. We may have only monocular vision, one eye being entirely blind or amblyopic. We may be dealing with a case of binocular vision where each eye sees separately, as in strabismus, but the two eyes do not work together because of the psychic suppression of the image in the deviating eye in order to prevent double vision. In either case, there is no double vision, still the patient has not binocular single vision. In order to have binocular single vision both eyes must simultaneously take part in the visual act, both eyes must fix the object, and an image must be formed in each eye, but the two images are fused together into one visual percept by the fusion mechanism.

MECHANISM OF BINOCULAR SINGLE VISION.

Binocular single vision is determined by the prompt action of the external ocular muscles. So long as these muscles or group of muscles act in harmony in otherwise healthy eyes, binocular single vision is present, and is obtained without special effort or expenditure of nerve force. The visual lines in these cases are parallel, and, in fixing an object the visual lines intersect at the point of fixation. The ocular movements are executed with ease in all directions; there is no lagging behind in the action of any muscle. Under such circumstances rays of light entering the eye after being refracted by the various media of the eye, form images upon a corresponding point of the retina (the refracting status of the eye being normal). The important part in the physiological mechanism of binocular single vision is that the images formed upon the retina shall be formed upon corresponding points, namely, the fovea, where as a result of the fusion power of the visual apparatus the two images are united into one definite visual percept. Such eyes are perfectly normal and no asthenopic symptoms result from the fusion of the two images. Not all eyes are so placed, however, by nature as to have their visual lines intersect at the point of fixation, and consequently images are not always formed on corresponding retinal areas, and double images under such circumstances would be observed, were it not for the fact that the muscular mechanism controlling binocular single vision can execute movements of adjustment to facilitate fusion of the two images. There is, undoubtedly, a fusion centre high up in the cerebral cortex that is stimulated by the retinal images to blend the two images into one definite percept. This fusion centre accomplishes its purpose by the aid of the external ocular muscles. Whenever images are formed on dissimilar points of the retina, these muscles bring about an adjustment by making the visual lines intersect at the point of fixation and bring the images on corresponding points of the retinæ ready to be blended by the fusion centre. This is the physiological effect of the fusion mechanism. It is well to bear in mind that there is an apparent muscular equilibrium; no deviation is manifest, but there is a constant nerve and muscle tension to hold the eyes in perfect parallel lines to prevent diplopia. It is in this nerve and muscle tension that the struggle for binocular single vision takes place. Up to a certain point the muscle, in response to a demand by the fusion centre, may be able to cope with the situation and to hold the eyes in such position as to enable them to bring about fusion, but it is done with the expenditure of extra nerve force which gives rise to symptoms of strain.

LATENT DISTURBANCE OF MUSCULAR EQUILIBRIUM.

Whenever we have a deficient muscular tone that is compensated by an extra effort of the fusion mechanism, so that there is no manifest deviation, we have a latent disturbance in the ocular motility. In all these latent disturbances we have an overwork of the ocular muscles and an extra expenditure of nerve energy that stimulates the muscles to overactivity. The heterophoric patient must either overwork his muscles and see clear, or allow a relaxation of his muscles and see either double or indistinctly. He chooses the former alternative and struggles for clear binocular single vision against an annoying double vision. He overworks his muscles. But this overwork of the external ocular muscles is productive of a chain of symptoms grouped under the title of muscular asthenopia. There comes, however, a time when the muscle is no longer able to respond to the extra nerve stimulus and can no longer continue the struggle for binocular single vision, consequently the muscle relaxes, and one eye no longer takes part in the visual act, the symptoms of course subside, but the eye is no longer held in a straight position, but deviates inward or outward and we have manifest deviation or strabismus. We may still have binocular vision; each eye may still retain its visual acuity when used separately, but the two eyes no longer work together, as the image in one eye is psychically suppressed in order to avoid double vision. Occasionally it happens that one of the eyes becomes amblyopic from nonuse; usually, however, the deviated eye is subnormal in its visual function. Not infrequently we see cases in which the deviation is manifest and yet binocular single vision is still present. These are cases of latent diplopia which can be elicited by placing a red glass in front of one eye, then the fusion apparatus is not able to blend the images. These patients are great sufferers and very difficult to cure. It is in these cases that the struggle for binocular single vision is productive of most serious results in giving rise to muscular asthenopia which lasts until the eye becomes strabismic. With the establishment of squint the symptoms usually subside, the struggle for binocular single vision is over, the deviating eye no longer takes part in the visual act.

SYMPTOMS OF MUSCULAR ASTHENOPIA.

The symptoms of muscular asthenopia are both local and general. The local symptoms manifest themselves in pain in the eyeball or in the superciliary region, especially after close application of the eyes to reading, sewing, or other work requiring good sight and attention, but this pain may be there regardless of close work. The conjunctiva as well as the eyelid may be hyperemic. There may be some twitching of the lid, and on lateral movement some ataxia of the ocular muscles. Headache is a common symptom. These patients suffer from headache which is not always localized, and not infrequently is felt in the morning. It is often occipital and radiates down the neck and the shoulder blades. In contradistinction to headaches caused by errors of refraction, the headache caused by disturbances in the balance of the external ocular muscles very often is more marked in the morning and may even grow less in intensity as the day progressess. This is somewhat analogous to the various muscular pains in the arms and shoulders that are more painful in the morning. The headache is often accompanied by dizziness, nausea, and not infrequently by vomiting. When the muscular imbalance is not corrected for any length of time other reflex symptoms may set in, such as nervous irritability, insomnia, general weakness, which ultimately culminate in neurasthenia. The vertical deviations are especially prone to give rise to asthenopic symptoms, while next in order of causation are the exophorias. The severity of the symptoms is not always, however, in proportion to the degree of the muscular deviation. Vertigo as a result of some muscular deviation is not infrequent and is usually caused by a latent or manifest diplopia which may also give rise to attacks of vomiting.

TREATMENT.

Asthenopic symptoms resulting from the struggle and effort to maintain binocular single vision, require relief, and in the majority of cases this may be obtained by optical adjustment. All muscular deviations giving rise to asthenopic symptoms should be corrected, no matter how low the degree. In fact, we are not to be guided by the degree of the latent muscular deviation, but rather by the symptoms produced. In those cases where the muscular imbalance is secondary to some complicated error of refraction, the correction of such error at once also remedies the muscular deviation and no further attention is necessary. Where the muscular disturbance is not dependent upon an existing error of refraction, then it must be remedied, if we are to relieve the symptoms. Our aim in the treatment of these cases is to provide binocular single vision without the necessary extra expense of nervous energy.

There is practically only one course open to us as far as therapeutic measures are concerned, namely, to prescribe prism glasses to aid the inefficient muscle in its struggle for binocular single vision. Where the disturbance is an exophoria resulting from a weak internal rectus muscle, we give prisms, base in, to relieve the strain from this weak muscle and thus enable it to enter into the visual act without producing reflex symptoms. When the external rectus muscle is weak and we have an esophoria, we place the prism base out. In vertical deviations we place the prism base up or down as the case requires. There are several forms of exercises for the purpose of strengthening the weak muscle without having recourse to prisms. All are based upon the same principle and all are practically of little use. Prism exercises, rarely if ever, produce a readjustment of equilibrium in the tone of the ocular muscles. The weak muscle may, as a result of prolonged exercise, succeed in overcoming some artificially induced deviation by means of prisms, but it rarely if ever brings the two muscles that are associated in lateral movements of the eye into a straight harmonious equality with the ordinary nerve impulse. It should also be remembered that prismatic exercises may be employed only in the so called exophoric type of deviation when there is an insufficiency of the internal rectus muscles. In all other forms of deviation prism exercises are practically of no avail. Even the exophoric type, where the muscle has been reeducated to overcome a prism of 25 $\triangle$ the muscle becomes again weaker as soon as the exercises are discontinued. It is practically impossible to continue these exercises forever or even for any length of time for economic reasons. Patients are not often willing to come to the physician's office often enough, and home exercises are not productive of the desired result. It is interesting to note that in hospital practice this therapeutic measure is not employed at all and is made use of only in office practice. This therapeutic measure may be considered a negligible quantity not deserving consideration. That leaves us only one remedy in the treatment of muscular imbalance, namely, prisms for steady wear. If we cannot make a weak muscle stronger so as to enable it to fix the object and fuse the images without special expenditure of nerve force and its subsequent unpleasant strain, we may still so alter the rays of light by means of prisms as to make them fall upon corresponding areas of the retina and thus give us binocular single vision, not as a result of overwork of the muscle, but as a result of the aid given by the prisms, the glass doing the work that otherwise would have to be done by the weak muscles.

When should muscular deviations be corrected by prisms? As soon as they give rise to asthenopic symptoms. In fact, some of the deviations should be corrected when detected without waiting for asthenopic symptoms to develop. All cases of hyperphoria or vertical deviation should be corrected at once without waiting for symptoms of muscular strain and a prism should be added to the corrected error of refraction. It is my practice fully to correct these deviations as long as the total deviation does not exceed six degrees when I place prisms of three degrees before each eye, one base up the other base down, depending upon whether we have a right or left hyperphoria. Prisms of a higher degree placed vertically cannot be tolerated by patients. But I have seen prisms of six degrees relieve symptoms where the deviation was eight or nine degrees. When the deviations reach a higher degree surgical means have to be employed to give relief. I always correct a one degree deviation,

even when there are no symptoms of asthenopia. To correct the error of refraction and leave the muscular imbalance uncorrected is not a good practice, as one degree of vertical deviation may be a potent factor in the production of muscular asthenopia, for the fusion mechanism is not well developed to blend vertical images with as much ease as lateral double images, and it is therefore essential to correct all these deviations and prevent rather than cure the symptoms of asthenopia and its possible aftereffects.

Low degrees of esophoria may not require correction so far as the muscular imbalance is concerned. Esophoria is often the result of an overactive accommodation impulse which stimulates the internal rectus muscles toward convergence, and with the correction of the existing error of refraction which lessens the accommodation impulse, it simultaneously lessens the actual amount of the esophoric tendency.

Higher degrees of esophoria I usually correct with prism glasses base out. I am in the habit of correcting carefully all cases of exophoria that present asthenopic symptoms, even though the deviation is only one degree. When the deviation is four degrees I correct them even though there are no symptoms. Only in selected cases do I use prism exercises. Surgical means for the relief of muscular asthenopia, while occasionally necessary, are usually not needed unless the latent divergence reaches at least twelve degrees. It is well to call attention to the fact that of many of these cases that come under our care require in addition to optical aid internal medication which will correct the result of the previous struggle for the supremacy of binocular single vision.

This short outline should give the general practitioner some idea of the problems the ophthalmologist has to meet. To give the general practitioner a fair outline of the scope of the work we are called upon to do and convince him not only of the necessity of ocular examinations and optical corrections in various cases, but also that these cases should not be intrusted to opticians and optometrists, is the aim of this paper.

917 Spruce Street.

ONE THOUSAND WASSERMANN REACTIONS.

From the George Washington University Laboratory, Washington, D. C.

By John M. Ladd, M. D.,
Indianapolis.

For the past four years or more medical literature has abounded in articles relating to Wassermann's reaction, and it is not my intention to add to this literature, but to present the percentages of the reactions we have found to prevail in dispensary, hospital, and private practice, basing them upon a thousand cases in the three services. While I was connected with the laboratories of the Casualty and Washington Asylum Hospitals, I was quite frequently asked: "In what percentage of cases do you find double plus (++) reactions in the patients of the hospital wards?" and: "What is the difference in percentage of double plus reactions in the white and colored races?" It is in answer to these questions that I tabulate as follows:

1. The dispensary patients comprised 42.50 per cent. of the 1,000 cases.

	Per Cent.
Reaction negative (—), in	52.80
" plus minus (+—), in	11.00
" plus (+), in	10.70
" double plus (++), in	25.50
	100.00 of 425 patients.

Of this number of patients, 68.80 per cent. were white and 31.20 per cent. were colored.

In the 25.50 per cent. of double plus reactions, 14.60 per cent. were of the colored race and 10.90 per cent. of the white race.

In the 52.80 per cent. of negative reactions, 29.80 per cent. were of the white race and twenty-three per cent. were of the colored race.

In the remaining 21.70 per cent. of plus and plus minus reactions, we find 13.90 per cent. to be of the white race and 7.80 per cent. of the colored.

In those patients in whom a diagnosis of lues had been made, I find that 43.70 per cent. gave a plus plus reaction, which, in my opinion, weakens statements made about dispensaries, that lues is present in nearly seventy-five per cent. of the cases.

2. Patients in the wards of George Washington University Hospital, comprising 44.90 per cent of 1,000 cases.

	Per Cent.
Reaction negative (—), in	71.20
" plus minus (+—), in	12.00
" plus (+), in	6.40
" double plus (++), in	10.40
	100.00 of 449 patients.

Of the 449 patients, forty-three per cent were female white and fifty-seven per cent. male white.

I find that 3.60 per cent. of the positive results were in the female white and 6.80 per cent. in the male white.

3. In the private cases of the hospital and in outside practice (12.60 per cent. of the total), I find the following percentages:

	Per Cent.
Reaction negative (—), in	62.50
" plus minus (+—), in	19.27
" plus (+), in	4.13
" double plus (++), in	14.10
	100.00 of 126 patients.

Of the 62.50 per cent. of negative reactions, I find that thirty-seven per cent. are in white females and thirty-three per cent. white males.

Of the plus and plus minus reactions, there are 48.20 per cent. under treatment.

From the foregoing figures, I think we can answer questions as to prevailing percentages in any of our services, and *en masse* we have the ratio per mille of population (all stations of life included) of either group of reactions, thus:

	Per Cent.
Reactions plus plus are found in	17.38
" minus are found in	62.09
" plus or plus minus are found in	20.53
	100.00

In making a comparative study of the two races I was astonished to find that the percentage of plus and plus minus reactions in our dispensary practice was 6.10 per cent. greater in the white population than in the colored, and in seeking a reason for the proportional increase, I have finally come to the conclusion that the white race has more faithfully taken the advice of our clinicians, and pursued continuous treatment at the dispensary, thanks to the continued effort in this work.

Dietetics, Alimentation, and Metabolism

Food and Food Preparation, in Health and Disease

FOOD AND EFFICIENCY.

By Martha Tracy, M. D.,
Philadelphia,
Professor of Physiological Chemistry, Woman's Medical College, Pennsylvania.

III.

VITAMINES.

(*Continued from page 853.*)

There are other substances among our food stuffs that are not fats, or carbohydrates, or proteins; substances which are of little or no value as fuel, but are of vast importance in building tissues, and in promoting the normal running of the body machinery.

These are compounds of whose chemical nature we are not certain, and to which the general name of vitamines has been given. Some of these so called vitamines contain nitrogen, but we know little of their chemical nature. They are found in the husks or bran of cereals, in milk and meat, in butter and codliver oil, in the fat of egg yolk, and in fresh vegetables, though always in minute amounts. Yet this very small amount of these mysterious compounds is absolutely necessary to the proper activity of the cell machinery. Without these substances in the food supply, though proteins, fats, and carbohydrates are adequate in quality and quantity, the young animal will not grow and the adult will fail to maintain a normal state of nutrition.

The curious disease called beriberi is rarely seen in America, but frequently in the Philippine Islands, Japan, China, and other eastern countries, and was long thought to be an infectious disease due to an unknown microorganism. In this disease of the nervous system numbness and stiffness are followed by gradual paralysis of the limbs due to a polyneuritis or inflammation of the nerves. We have discovered that this condition is due to a lack in the diet of these peculiar vitamines. The peoples in whom beriberi develops are accustomed to live largely upon polished or white milled rice, rice from which the husk has been removed and with it these mysterious life giving substances. If unpolished rice is eaten, or sufficient fresh vegetables of other sorts, or meat, or if some of the rice bran is taken with the food, either the disease does not develop or the person suffering from it will recover promptly.

There is a disease of nutrition called scurvy, which we do not often see today, especially in this country. It was common when fresh vegetables and fruits were less available to every one, and salted meats were largely used, as in the long voyages of sailing ships, or in prisons. We have learned that fresh foods, especially vegetables and fruits, orange and lemon juice, supply some not understood, and perhaps vitamine need of the body and thus prevent development of the disease.

Bones constitute a tissue which is composed largely of calcium phosphate, and we must have food which contains phosphorus and calcium in order to build this tissue. Thus inorganic salts are indispensable in our dietary. A certain amount of sodium chloride or table salt is present in the body fluids; iron is essential for building hemoglobin, the characteristic protein of the blood; calcium and potassium salts are also needed in the blood and cells.

A disease called rickets occurs in undernourished children. Here we have as the most conspicuous symptom the imperfect bone development with consequent deformity of skull and limbs. The disease appears to be related to some lack in the diet, which in some unknown way influences conspicuously the proper use of inorganic salts, and there results deficient ossification.

The inorganic salts play a significant part in the nutrition of the body in quite another way. The normal body tissues and fluids are neutral or slightly alkaline in reaction. This appears to be necessary for solution of materials, and for maintenance of the conditions best suited to tissue combustions. The salts are of first importance in maintaining this neutral or alkaline condition.

If acids or acid forming substances are taken in the food, or if acids are produced in the body by cellular activities, salts of potassium and sodium and ammonium will react to neutralize the acids and thus save the tissues from their deleterious effects. If too much acid is ingested or formed within the body, however, such neutralization may be inadequate, and abnormal states included under the term acidosis may result. The food must therefore be chosen with some regard to its content of acid forming and base forming substances.

From what has been said, then, we are in a position to appreciate the definition of nutrition given by Professor Lusk: "Nutrition is the sum of the processes concerned in the growth, maintenance, and repair of the living body as a whole, or of its constituent organs."

We see that the normal continuance of these processes involves transformations of energy, latent in foodstuffs, into heat and work and chemical reconstruction in the animal body. The activities of the cells by which the building of tissue is accomplished, are best carried on at a temperature of about 98.6° F., which must be maintained by oxidations in the cells, the burning of fuel.

The internal work of the animal engine, which is manifested in the movements of the digestive tract, of the chest wall in respiration, and in the never ceasing activity of the heart muscle, is all essential to the growth, maintenance, and repair of cells, and this work all represents energy liberated by these same oxidations in the cells.

Normal nutrition, then, involves the adequate supply of tissue building foods; proteins, inorganic salts, water, a little carbohydrate and fat, and very minute quantities of unknown vitamines; also a sufficient amount of fuel food, chiefly carbohydrate and fat, to keep the machinery in motion.

Malnutrition means the unsatisfactory working of

the machinery because of inadequate or excessive supply of some one or more of these foods. We cannot leave this phase of the subject, however, without brief reference to certain regulating influences within the body itself, which effect the distribution and use of foodstuffs in a manner quite beyond our dietetic control.

There are in the body certain so called ductless glands, groups of cells which produce chemical substances that are not poured out through a duct, but which diffuse from the cells into the lymph and blood streams in such minute amounts as to be almost if not quite beyond our power to detect them, and yet are of such significance that if these glands are removed or diseased, the whole machinery of the body is disturbed.

There is the thyroid gland lying in the neck, the adrenal glands lying just above the kidneys, the pituitary body lying at the base of the brain within the skull, and the pancreas, which, in addition to the juice which it pours through a duct into the intestine to play a part in digestion, produces also one of the internal secretions which diffuse into the blood.

In the normal subject these ductless glands are performing their physiological duties smoothly and uninterruptedly, and if we do our part in providing proper food supply, the engine runs satisfactorily and nutrition is normal. If these glands are not functioning normally it is because there is a diseased condition or has been an error in development of the gland which no dietetic regimen can repair. That side of the control of nutrition is not a part of our study, but must be left to a discussion of the treatment of disease.

Granting that we have a normal body engine, it is our province to keep it normal by providing the materials required for the daily needs.

(*To be continued.*)

Discrepancies in Current Systems of Dietetics.—Axel Emil Gibson (*Medical Standard*, October, 1916) says that in the complexity of modern life, thumbscrew standardization of individual diet is unsafe and unreliable. Moral disposition, nervous intensity, nationality, preceding habits of life, diet, etc., must be accepted as indispensable factors, necessary for a scientific determination of the specific needs in individual dietetics. As digestion depends for its efficacy on the nervous disposition of the individual, so a fruit diet may mean added health and power to the well nourished, self possessed, equipoised type, but disastrous to the neurasthenic highly strung, and eccentric. Milk may paint the pink of health on the cheeks in one case, the yellow of jaundice on those of another. Sour pickles, sauerkraut, vinegar, and beer may go well with a diet of salami, pork, frankfurter sausage, and Roquefort cheese, while for a person living on grains, fruits, and vegetables they lead to digestive disaster. A poisoned system requires antidotal poisons for its neutralization, and physiological or digestive tolerance is a matter of metabolic power of neutralization. The rudimentary principles of a hygienic diet may be summed up in the avoidance of physiologically intolerable combinations, such as acids with starches, milk with proteids, meat and carbohydrates—or, in other words, fruit with any form of food; meat with milk, fruit, or cereals; free sugar in any man made combination, and acids with meals. In general avoid any product not grown on a tree or attached to a root. He maintains that to most dietitians the main object is to prepare food mixtures with a view to moving the bowels, and that this is a misconception of the real value of diet. The bowels should not be irritated, but nutrition should constitute the basic factor in curing constipation. He holds that bread should be made up of no other ingredients than those present in the complete grain, unsifted, unbleached, unmixed, but ground sufficiently fine to avoid the irritation that may follow the passage of coarse, indigestible grain kernels. The baking of the bread should be thorough and with the end in view of dextrinating its starch and destroying its yeast spores. While a piece of good bread may be sufficient to sustain routine animal existence, it is not sufficient adequately to sustain the high tensioned cellular energies, so it is better to add three or four black figs or prunes, and a similar amount of walnuts to a breakfast of whole wheat bread. Another meal of physiological sufficiency may be found in a single dish of cottage cheese, if to it is added a teaspoonful of ground brazil nuts, a tablespoonful of chopped green onions, lightly dusted with powdered chili pepper as an aid to the digestion of the cold mass, enjoyed with a slice of whole wheat, well toasted bread, and unsalted butter. Then there is a meal of an Irish potato with a soft, poached egg, a boiled or steamed onion, and an ounce of unsalted butter. Then at the time of retiring, when the stomach has had time to empty itself, a bunch of sweet grapes, or a ripe, fresh apple rounds up the dietetic program of the day. Thus, he avers, the three cardinal virtues of a rational diet are achieved—digestive facility, nonfermentative absorption, and an *n*th power of efficiency. Without the attainment of these three objects, diet remains a mere vegetative act, a haphazard feeding, gauged either by an overwrought asceticism of elimination, or the insane promptings of an overstimulated, unreliable, despotic appetite. A vital balance must be maintained in the diet, and the fact must be constantly kept in mind that man is an individual *per se*, and refuses constitutionally to be standardized or generalized into any fixed system of diet.

Raw Starch in the Treatment of Diabetes.—E. B. Knerr (*Journal of Missouri State Medical Association*, September, 1916) describes his treatment of diabetes as consisting of placing the patient in a hospital or sanatorium and putting him on raw starch and water until all the sugar had been burned out of his system and circulation. This may take from one to four days, though glycosuria usually disappeared in from twenty-four to thirty-six hours. A dram of starch in a glass of water every two hours is all the nourishment allowed until the urine is sugar free. No preliminary days of reduced diet are necessary as in the Allen treatment, and therefore the excessive hunger, thirst, and polyuria are unknown under the use of raw starch, which satisfies the patient's craving for carbohydrates. As

soon as the urine is sugar free the patient may be allowed green vegetables, such as lettuce or celery, with salt and a soft egg; the allowance is gradually increased by the addition of meats and boiled vegetables. The dram of raw starch, however, should be taken three times daily for months, for a year or more. Citric fruit juices should be used to control acidity of the secretions, except where they aggravate the glycosuria.

Butter Not Adulterated.—During the summer of 1915, an investigation was made by the Board of Health of New York City, directed especially to ascertain whether oleomargarine was to any appreciable extent served in place of butter by restaurants and hotels; 123 samples were procured from various sources.

The chemical examination included the tests for oleomargarine and excessive moisture; 121 samples were passed. Two samples showed excessive moisture. Hearings were held in these two cases; it was shown that the butter had been purchased in good faith. Therefore, it is evident that the substitution of oleomargarine for butter must be rare. Even "washing of butter," as indicated by abnormal water content, is not generally practised.

Sale of Milk from Unregistered Dairy.—According to *Public Health Reports* for September 15, 1916, after a dispute between a California cheese manufacturer and a dairyman who had supplied him with milk, the cheese manufacturer refused to pay for milk which he had used, on the ground that the dairy from which the milk was delivered was not registered with the State authorities as required by law. The purity of the milk was not questioned, and it complied with the standards established by the State law. The California Court of Appeals decided that the law requiring registration of dairies did not provide any penalty for failure to register other than a fine or imprisonment; that the sale of the milk was not unlawful; and that it must be paid for. The opinion is published in the same issue of *Reports*, page 2523.

Treatment of Rickets.—Eric Pritchard (*Pediatrics*, September, 1916) bases his treatment upon a new conception of the pathogenesis of the disease which attributes it to the results of the stimulation of protective mechanisms controlling the disposal of excess of nutritive material. These mechanisms are three: 1, The storing of the excess as food reserves. 2. The complete oxidation of the excess and the excretion of the end products. 3. Incomplete oxidation of the excess with the production of acid bodies and a resulting acidosis. The last is the most important in the production of rickets, for it leads to the exhaustion of the alkali mineral reserves and sets up a compensatory hyperactivity of the blood forming organs. The excess in diet may not be actual in the ordinary conception of an infant's diet, but still may be present as a relative excess. It is further fostered by conditions of excessive heat, deficient ventilation, and restricted exercises—all common in the families with rhachitic children. On the basis of these facts the treatment consists in: 1. The creation of a demand for food by massage, passive and resistance movements, cold douches, and open air living. 2. Neutralization of the acid bodies by administration of alkalies. 3. Relief of anemia by the administration of the carbonate of iron. 4. Building up the nervous system by giving phosphorized cod-liver oil (one in 10,000). 5. Restriction of excess of nutriment by a diet of milk alone in limited quantity. The strikingly beneficial results of such a plan of treatment are shown by the record of a typical case.

Milk Diet Prior to Use of Salvarsan.—A casual observation by Lionel L. Westrope (*Brit. Med. Jour.*, September 30, 1916), pointed to the fact that patients who for one reason or another had been receiving an exclusive milk diet did not manifest symptoms after doses of salvarsan or kharsivan. This observation was followed up and 100 injections of the drug were given to patients after a twenty-four hour period during which the diet was limited to two litres of milk. After the injections the patients were allowed to return to full diet. In seventy-seven of these cases there were no toxic symptoms whatever and in the others the symptoms were unusually mild and consisted of headache, vomiting, and diarrhea. No patient treated thus had rigors and only one showed albumin in his urine after the injection. Without the milk diet the patients always complained of severe headache and vomiting, and the tendency to other unfavorable side actions was marked.

Danger of a One Sided Diet.—Unless care is exercised in selecting food a diet may result which is one sided or badly balanced—that is, one in which either protein or fuel ingredients are provided in excess, says W. O. Atwater, Ph. D., in *Farmers' Bulletin* No. 142, United States Department of Agriculture. If a person consumes large amounts of meat and little vegetable food, the diet will be too rich in protein and may be harmful. On the other hand, if pastry, butter, and such foods are eaten in preference to a more varied diet, the food will furnish too much energy and too little building material.

Extreme illustrations of such a one sided diet are found in the food of persons who live largely on bread and tea, or others who live on corn meal, fat pork, and molasses. The "hog and hominy" diet supplies liberal quantities of energy, but is very deficient in protein, as illustrated by the diet of negroes in the "black belt," with sixty-two grams of protein and 3,270 calories of energy a day for each man.

It should be said that most of our dietary standards have been deduced from food investigations conducted with persons living in temperate climates. It is not improbable that those living in arctic regions and in the tropics require nutrients in different proportions. It is a matter of common observation that in arctic regions much larger amounts of energy yielding material, principally fat, are consumed than in warmer climates. Less definite information is available regarding food requirements in the tropics; but it seems probable that when proper dietary conditions are followed, somewhat less food is consumed than in temperate regions, and that the nutrients are in somewhat different

proportion. It is certain that a diet which would be entirely satisfactory in frigid regions would be one sided in the tropics, and vice versa. This subject is one which needs further investigation before definite conclusions can be drawn regarding the foods best fitted for extremes of heat or cold.

Contemporary Comment

No Goods on Approval.—The supervisors of San Francisco county, according to the *Southern California Practitioner* for October, 1916, recently passed an ordinance that only wants the mayor's signature to become a law, forbidding the taking of wearing apparel, household goods, etc., home on approval. This ordinance, backed by the merchants, puts the burden on them by prohibiting them from taking back goods of varieties likely to suffer by contact with the person, or the household and its furnishings.

After all, it is an unwelcome thought to think of trying on socks, shirts, and underwear that may have been through the same process on the person of one suffering with syphilis, gonorrhea, skin disease, tuberculosis, or even lice. Los Angeles would do well to pass a similar law, as it would do a whole lot to stop the spread of contagious disease.

Infant Mortality and Social Welfare.—What connection is there between infant mortality and social welfare, and if there is such a connection is it a close one? This question is asked by *Pediatrics* for October, 1916. The editor goes on to say: The first part of the question is somewhat absurd, for it is obvious to any thinking individual that there is a relationship between infant mortality and social welfare, but how intimate this relationship is, is "another story" as Kipling might say. Newsholme, the British public health authority, lays much stress on the closeness of this connection, and goes so far as to say that infant mortality is the most sensitive index we possess of social welfare and then adds: "If babies were still well born and well cared for, their mortality would be negligible. The infant death rate measures the intelligence, health, and right living of fathers and mothers, the standards of mortality and sanitation of communities and governments, the efficiency of physicians, nurses, health officers, and educators." Which means to say that the country in which the infant mortality is lowest, not only contains the most intelligent and healthy fathers and mothers, but the most moral, hygienic and efficient population. This is true to a very large extent, for countries in which infant mortality is lowest, are distinguished by the intelligence and morality of its inhabitants, for after all, morality is a question of public health; where morals are lax, diseases flourish, and vice versa. The Scandinavian countries are excellent examples of the truth of these dicta, for by wise and far seeing methods they have so largely decreased their infantile mortality that at the present time Sweden, for instance, is in the first rank regarded from the baby saving standpoint. Up to the present time this country compares unfavorably with many European countries so far as a low infant mortality is concerned. We are as lavish of life as we are of our material products and the day is fast approaching, if it has not come already, when we must take steps to conserve our resources, and especially our human resources. If Newsholme's dictum be applied to us, we have been weighed in the balance and found wanting. There are signs everywhere, however, that in America earnest men and women are awaking to the menace of infant waste and are putting and preparing to put efforts into force to diminish infant mortality and to rear children that will be of use to the nation mentally and physically.

The Medical Reserve.—There are 300 vacancies in the U. S. Navy for physicians, observes the *New Orleans Medical and Surgical Journal* for November, 1916; in the Army nearly 100, and in the Public Health Service about fifty. These are tempting opportunities for medical graduates under thirty-two years of age. Moreover, the projects under way promise more rapid promotion than formerly, and while waiting for promotion the medical officer is much better paid than the majority of men in the first five years of the practice of medicine.

Meanwhile there is a large activity in developing the Medical Reserve Corps in groups in the various states, so that every available man who wills is to be invited to join the Medical Reserve Corps. Many young men are fearful of contracting such a relation with the government, because of the likelihood of being deprived of their growing practice and of being sent into mobilization upon unlimited terms. The willingness to serve in case of real emergency, however, is the first step toward a proper organization, and if the profession generally were assured that the aim of all present effort is toward a general plan of preparedness, through the expansion of the reserve corps, the number of applications might be larger. In case of actual war probably very few medical men would refuse to serve, but if war came tomorrow they would not be particularly useful if they had no conception of the place in which they might be needed.

Already there is a good number of physicians in the list of the Medical Reserve Corps of the army, and for two years they have had the opportunity of camp experience under government instruction. With several thousand the instruction could be more widely distributed and, in the end, there would be ready for emergency enough men to satisfy a large army need. In the past the young, or older medical graduate has had to drift into the army, navy, or Public Health Service, and because of the limited number of positions in these government services there was naturally no encouragement, but the way was always made hard with the idea of both limiting the number of applicants and of selecting the best of them.

As the need of more medical officers has come about, there should be a general consideration on the part of the profession of the larger opportunities for the young medical graduates and they should be encouraged to go into the Medical Reserve Corps as a way toward the regular services or to active usefulness in preparedness should the occasion arise.

HEREDITARY SYPHILIS.

The development of the present conception of syphilis and the abrupt changes which have established themselves in its treatment, illustrate well the advance of medical science in the past decade. The unusual attention and interest which recently have attended the progress of our knowledge of cerebrospinal syphilis, has served perhaps to obscure another aspect of this protean disease which is likewise of no small importance. We refer to hereditary syphilis; its recognition, treatment, prevalence, and importance have never received the attention they deserve. Because of these facts, timely interest attaches to a group of papers presented in a symposium on syphilis before the section in diseases of children at the Detroit meeting of the American Medical Association (*American Journal of Diseases of Children,* October, 1916).

In this symposium, Churchill and Austin discuss the prevalence of hereditary syphilis. In the literature they found an incidence varying from two to fourteen per cent. in Europe and America. Their own clinical and laboratory series of 695 patients in the Children's Memorial Hospital in Chicago showed an incidence of 3.3 per cent. of hereditary syphilis. According to their data, in hospital infants, and children in New York, Chicago, St. Louis, and San Francisco, the incidence ranges from two to six per cent.

Abner Post reviews the clinical picture of well marked hereditary syphilis in infants and small children, and points out diagnostic aids in mild and atypical cases hard to recognize. A marasmic condition may be the chief clinical evidence of the disease. Snuffles are not always due to adenoids, and syphilitic narrowing of the nasal fossæ gives the same symptoms as adenoid obstruction. Proper emphasis is laid on bony changes, especially cranial exostoses, which favor the frontal and parietal regions. Such exostoses, especially when symmetrical, must not be ascribed to rickets. Retarded ossification in the long bones and extreme separation of epiphysis and diaphysis often going on to displacement of the former, are revealed by the x ray, as is also the frequent accompaniment of periostitis. As a result of these bony changes the child is prone to cry excessively at night. Post urges the value of careful radiological study. Other less distinctive signs are alopecia, onychia, the various skin manifestations, a distinctive cry, enlarged lymphatic glands, and loss of weight with no evident cause.

P. C. Jeans states that the Wassermann reaction is "positive in practically 100 per cent. of the late cases in childhood." The absence of a history of syphilis in the parents, even when both parents have a negative Wassermann reaction, he considers of no importance in the diagnosis of the hereditary disease, as he found that in less than fifty per cent. of his cases the father gave a positive Wassermann. Radial linear scars about the mouth, he states, are caused by nothing else. The same is true of mucous membrane perforations, and of immobile pupils, while irregular pupils and synechiæ are very suspicious. Jeans notes the peculiar difficulty in many cases of distinguishing between syphilis and tuberculosis.

In summing up a review of recent work on syphilis, H. P. Towle concludes that the new arsenical preparations have proved their worth, while in no wise has the value of mercury and iodides been decreased. Similarly the Wassermann and other serum reactions have proved of definite worth, but have not decreased the value or importance of careful clinical observation and diagnosis. Thus the newer procedures in diagnosis and treatment have not supplanted the old, but have been added to them, to the great advantage of the physician's control of the disease.

Sylvester, in a contribution to the treatment of hereditary syphilis, urges vigorous treatment of the pregnant syphilitic mother, and a general employment of neosalvarsan and mercury as in acquired syphilis. He finds neosalvarsan the best arsenical preparation. After treatment has continued for at least two years, and has been followed at an interval of six months by a negative Wassermann reaction, the case may be considered cured. Central nervous lesions do not yield readily, but even here the outlook is not discouraging. Sylvester advocates treatment of latent cases. DeBuys and Sanford consider the luetin reaction more valuable than the Wassermann in hereditary syphilis, but maintain that both should be obtained.

IGNIS FATUUS.

The will o' the wisp, *Iguis fatuus,* has never been explained, though much thought has been expended upon it; neither has the source of discomfort and depression in badly ventilated rooms been cleared up, the great amount of time, work, and money that has been spent over the question, notwithstanding.

Some well planned and painstaking work on the subject of ventilation has been recently carried out, in which valuable findings have been made concerning the influence of temperature and moisture and motion of the air upon those whom it surrounds. While those who have carried out these experiments, however, are convinced of the effect of these physical states of the atmosphere, they do not go so far as to say that they have solved the problem of ventilation. Even those who seem most assured that there is nothing more to "bad air" than high temperature, moisture, and lack of motion, still show a quaver in the tone with which they make the announcement.

If this is all there is to the problem of ventilation, why was it not solved long ago? Rooms have not always been kept superheated nor overmoist, and in many modes of ventilation there has been motion of the air. Again, if these simple faults in its atmosphere are corrected, the horrid smell of a badly ventilated room still remains, an odor that is often overpowering to one who coming from pure air suddenly makes its acquaintance. Foul smelling air means air containing foul material from the respiratory passages, skin, clothing, or alimentary tract of the occupants of the room. It will have to be proved that these exhalations, these "dead breaths of men," as Henry Ward Beecher so well called them, are not harmful, before it is accepted that ventilation is purely a matter of temperature, moisture, and motion.

There can be no question of the good effect on general metabolism of sufficiently low temperature, of moderate moisture, and sufficient agitation of the air in a room, but until it is proved beyond question that the foul materials which are undeniably present in "bad air" are harmless, the old carbon dioxide test remains the best. To do away with the limit, set by this test, for good ventilation is just what is desired by owners of public halls and school buildings. They would delight to save expense, by closing all ventilators, by keeping the temperature of the air at a minimum, by extracting a little moisture if necessary, and by running a few fans to agitate the air. But no self respecting person would care to encounter the odor of such a room, and we doubt if the results of its occupancy would be wholly healthful. Besides, the public would not stand for abnormally low temperatures. Good sense is often better than half baked science. Good practice is better than bad theory.

Practical study of ventilation seems to have been begun by Stephen Hales less than two hundred years ago; by changing the air in the Savoy prisons he is said to have reduced the mortality greatly, and his apparatus proved so valuable that it was introduced into France. Two hundred years may be too brief a time to solve the problem of ventilation; science is yet exceedingly young and all physiological problems are extremely complicated. Moreover, we do not as yet know all about the chemistry of the air; there are at least four of its elements about which the pages of chemistry so far are blank.

THE SYNDROME OF SO CALLED CONCEALED TUBERCULOSIS.

In a paper on this subject, Head (*Journal A. M. A.*, LXIII, 1914, page 996) of Minneapolis, ably discussed the problem of the relationship of concealed tuberculosis to many cases of so called tuberculosis; in a second paper (*American Journal of Medical Sciences*, October, 1916, page 582) he presents the gist of his argument.

He makes a plea for the recognition of a clinical picture or symptom complex which he calls concealed tuberculosis. It occurs usually in persons under twenty-five years of age. A history of exposure to tuberculosis, even as far back as childhood, may be present. The symptoms consist of manifold manifestations of nervous and physical exhaustion, most patients presenting several of the following: Indigestion, headache, constipation, mental depression, cold hands and feet, backache, neckache, asthenopia, voice tire, clearing of throat, crying spells, chilliness, loss of weight. As

a rule these symptoms continue for a number of years, at times with periods of improvement, succeeded by relapses under unusual nervous and physical strain, frequently with partial or complete breakdown. The physician usually finds a poorly nourished and highly strung patient, whose features are angular, cheek bones high, chest and abdomen long, arms and legs slender, and reflexes active.

Carefully made and often repeated physical examinations will not disclose evidence of organic disease. Usually enteroptosis can be detected. The findings in the lungs are doubtful or negative. The rate of the pulse is generally increased, while the temperature is normal or shows an afternoon rise to 99.2° or 99.4° F. or higher. The laboratory findings, including the Wassermann test, are negative for organic disease, and the Röntgen ray studies of the lungs for tuberculosis are doubtful or negative.

It is not astonishing, therefore, that a diagnosis of so called neurasthenia is made; but make a von Pirquet skin test and it will be promptly positive, and give a subcutaneous injection of tuberculin and it will always react positively. For this reason, Head argues, this symptom complex may be regarded as a special type of tuberculosis, without focal evidence, but discovered by a specific test. Head contends that most subjects who give the picture of nervous or physical exhaustion have physical disease of some sort, and that this will be unearthed if the examination is thorough; it may be tuberculosis, syphilis, ductless gland disorder, nephritis, or sepsis. In some of these patients, labelled neurasthenic, in whom examination fails to detect organic disease other than tuberculosis, the number of times in which a positive reaction to a maximum dose of tuberculin given subcutaneously will be obtained is astonishing and instructive. Head asserts that the number of negative reactions is small if the examination is careful and thorough and a large series is studied.

These cases are quite common and can be recognized by the specific tuberculin test. When properly diagnosed, they will be treated as tuberculous, which they are, and not as some form of nervous exhaustion, which they are not.

As to the exact site of the tuberculosis in the cases discussed here, no positive and final statement can be made. Sometimes the lesion is in the bronchial glands, sometimes at the hilum of the lungs, and in other cases in the mesenteric glands. In some there may even be some slight pulmonary involvement, either not sufficiently extensive or else too deeply placed to permit of detection by physical examination.

AN EXPLANATION OF BABINSKI'S SIGN.

One of the first tests learned by the aspiring neurological student is that for Babinski's reflex. He is told that its presence suggests organic brain disease or paresis. He learns that it is a comparatively slow dorsal extension of the great toe when the plantar reflex is tested, together with the slight spreading apart of the other toes. If the patient is in bed, as obviously he should be, there is also a slight rotation of the thigh on the hip and a contraction of the fascia lata. The student is also taught to distinguish the true Babinski from the Strümpell, the Oppenheim, the paradoxical, the Mendel Bechterew, and the Chaddock. With all this he does not learn the cause of the phenomenon, for the good reason that it is not known. It is in fact a unique thing, it is not the exaggeration, diminution, or abolition of a reflex, but the complete inversion of it—as if the gastric glands should secrete an alkali.

Theories have been offered in explanation of this sign, but the most plausible are those which take into account the significant fact that it occurs in young infants, but disappears when they have learned to walk. This would suggest that it represents some faculty which has been lost in the course of phylogenesis, appears in ontogenesis for a short time, and then is lost, never to reappear except when in the course of a disease the communication between the spinal cord and the cerebrum is interrupted. We would then appeal to comparative anatomy for some confirmation of this theory.

This is what has been done by a Russian neurologist, M. Astwazaturof (*British Medical Journal*, August 12, 1916), in a series of papers. In man the foot performs a purely static function, but in the lower animals it is prehensile. In the act of grasping, the great toe opposes the others. In man the opponens hallucis is absent and the first metatarsal bone is parallel to the others instead of making an angle with them.

It is possible that in a certain stage of evolution of the grasping function into the purely static one, there was a period when the flexor act was limited to the second, third, fourth, and fifth toes, the great toe being extended. Babinski's sign is probably a vestige of this condition. The great toe of the Hapalidæ has a nail instead of a claw, and is not prehensile, which fact seems to bear out this theory.

SO CALLED CLERGYMAN'S SORE THROAT.

George Steele-Perkins communicates to the *Lancet* for October 21, 1916, his views on the pharyngitis and laryngitis of public speakers. He states that it is now over thirty years since he first asked

himself why we speak of the condition as clergymen's sore throat and not as lawyers' sore throat. Why is this condition so rarely seen in lawyers who use their voices more than clergymen, and in stuffier atmospheres? On thinking over the matter the only difference the writer could perceive between a clergyman's and a lawyer's speaking was that a clergyman spoke *down* to his congregation, and a lawyer spoke *up* to the judge, the former thus pressing on his larynx and causing congestion, whereas the lawyer had his larynx and throat in a normal position, or rather in a hypernormal position. From that time he has always advised such patients to speak looking *up* to their audience and never *down*. He has used no local applications or treatment except to rectify a condition such as granular pharyngitis, but where necessary he has suggested a rest of voice for two or three months. In all cases this plan has been successful.

News Items

Northwestern Ohio Medical Society.—At the annual meeting of this society, held in Toledo on October 21st, the following officers were elected: President, Dr. J. R. Tillotson, of Delphine; vice-president, Dr. F. S. Replogel, of Bryan; secretary, Dr. A. S. McKetrick, of Kenton. Next year's meeting will be held in Lima.

Tuberculosis Preventorium in Poughkeepsie.—A new preventorium that will accommodate sixty children is to be erected at the Samuel W. Bowne Memorial Tuberculosis Hospital in Poughkeepsie, N. Y. Mrs. Bowne contributed $25,761 toward the fund and the city of Poughkeepsie gave $8,872 for plumbing, heating, lighting, water, and sewage systems.

The New York Neurological Society.—At a meeting of this society, which will be held at the New York Academy of Medicine, Tuesday evening, November 14th, at 8:30, the subject for discussion will be Poliomyelitis; Its Diagnosis and Treatment and the Management of the Recent Epidemic. Papers will be read by Dr. William M. Leszynsky, Dr. Frederick Tilney, Dr. B. Sachs, and Dr. C. L. Dana.

Eastern Medical Society.—At a stated meeting of this society, held Friday evening, November 10th, in the Hotel Brevoort, Dr. George W. Crile, of Cleveland, read, by invitation, a paper on Clinical Considerations of the Cancer Problem. The subject was discussed by Dr. Francis Carter Wood, Dr. Robert T. Morris, Dr. Willy Meyer, Dr. Israel Strauss, and others. Dr. Samuel J. Kopetzky exhibited a case of traumatic labyrinthitis followed by cerebellar abscess, in which operation was followed by recovery.

American Public Health Association.—At the annual meeting of this association, held in Cincinnati, October 24th, 25th, and 26th, Dr. William A. Evans, of Chicago, was elected president, and other officers were elected as follows: Dr. John H. Landis, of Cincinnati, first vice-president; Dr. Maurice McD. Seymour, of Regina, Sask., second vice-president; Dr. Manuel Iglesias, of Vera Cruz, Mexico, third vice-president; Dr. S. N. Gunn, of Boston, reelected secretary; Dr. Lee K. Frankel, of New York, reelected treasurer.

Meetings of Medical Societies to Be Held in Philadelphia during the Coming Week.—Monday, November 13th, Samaritan Hospital Medical Society, Aid Association of the County Medical Society (annual); Tuesday, November 14th, Pediatric Society, Wills Hospital Ophthalmic Society, Medical Examiners' Association; Wednesday, November 15th, Section in Otology and Laryngology of the College of Physicians; Thursday, November 16th, Section in Ophthalmology of the College of Physicians, Northeast and Southeast Branches of the County Medical Society; Friday, November 17th, Jefferson Hospital Clinical Society.

The National Committee for the Prevention of Blindness, in its *News Letter* for October, cites a case of blindness from wood alcohol poisoning after drinking liquors secured at a Brooklyn wholesale grocery. Investigation showed that the bottles, bearing counterfeit labels, contained from forty to fifty per cent. of wood alcohol.

Memorial Library at the Woman's Medical College.—As a memorial to his son, Dr. George Carlton Dominick, who died at sea recently, Mr. M. W. Dominick has arranged to equip and endow the new medical library at the New York Medical College and Hospital for Women, in West 101st Street. Doctor Dominick was an instructor at the college for a number of years.

A New Medical Society Organized in the South.—The West Florida and South Alabama Medical Society was organized at a meeting of physicians held in Pensacola, Fla., on October 27th, with the following officers to serve for the first year: Dr. Louis de M. Blocker, of Pensacola, president; Dr. M. S. Davie, of Dothan, Ala., first vice-president; Dr. E. Porter Webb, of Laurel Hill, Fla., second vice-president; Dr. F. A. Brink, of Pensacola, secretary and treasurer. The association will embrace all of West Florida and all adjoining counties of Alabama as far as Mobile.

Bronx County Medical Society.—The following program has been arranged for a regular meeting of this society, which will be held at Ebling's Casino, Wednesday evening, November 15th, at 8:30 o'clock: Dr. I. M. Heller will present the report of a case of radical treatment of peritonsillar abscess; Dr. Parker Syms will read a paper on Cancer of the Breast, which will be illustrated by lantern slides and discussed by Dr. Willy Meyer, Dr. Henry Roth, and others. Dr. Edward R. Cunniffe will read a paper on Intestinal Obstruction which will be followed by a general discussion.

Dr. George Wythe Cook Honored.—Dr. George Wythe Cook, of Washington, D. C., former president of the Medical Society of the District of Columbia, was the guest of honor at a banquet given on the evening of October 28th, on the occasion of his seventieth birthday. Dr. Frank Leech was toastmaster, and among the speakers were Dr. E. V. Davidson, Dr. S. S. Adams, Dr. E. A. Balloch, Dr. P. S. Roy, and Dr. W. M. Barton. Arrangements for the banquet were in the hands of Dr. Charles W. Richardson, Dr. T. N. McLaughlin, Dr. A. W. Boswell, Dr. S. S. Adams, Dr. J. R. Wellington, and Dr. H. C. Macatee. At the close of the banquet a silver loving cup was presented to Doctor Cook by the members of the society.

Personal.—Dr. C. Lincoln Furbush, of Philadelphia, has been appointed special assistant to the American Embassy in Berlin and medical inspector of the prison camps of the Allies in Germany.

Dr. Elbert M. Somers, formerly superintendent of the Long Island State Hospital and medical inspector for the State Hospital Commission, announces that he has opened an office for the practice of neurology and psychiatry at 33 Lefferts Place, Brooklyn.

Dr. Le Grand Kerr, of Brooklyn, was the guest of honor at a dinner given by the parents of the children he had treated for poliomyelitis during the recent epidemic. Doctor Kerr was presented with a bronze statue of the Winged Victory by Barrias, to symbolize his success in fighting against the disease.

Dr. R. Tait MacKenzie, of Philadelphia, who returned home recently after serving a year in the Medical Corps of the British Army, delivered an address on How Disabled Soldiers Are Reconstructed in an English Convalescent Camp, before the Philadelphia Clinical Society, Monday evening, November 6th. The lecture was illustrated by lantern slides.

Dr. William Gilman Thompson has resigned as professor of medicine at Cornell University Medical College, and Dr. Lewis A. Conner, professor of clinical medicine, has been appointed to succeed him.

Dr. Frank Maltauer, of Cincinnati, has been appointed associate professor of bacteriology and public health at the University of Tennessee.

The Tri-State Medical Society, of Illinois, Missouri, and Iowa, met in annual session at Kansas City, Mo., on October 26th and 27th, and elected the following officers: Dr. G. Wilse Robinson, of Kansas City, president; Dr. C. B. Francisco, of Kansas City, vice-president for Missouri; Dr. Charles M. Dargan, of Pontiac, vice-president for Illinois; Dr. C. S. Chase, of Iowa City, vice-president for Iowa; Dr. Charles H. Parkes, of Chicago, secretary and treasurer. Next year's meeting will be held in Iowa City.

Kentucky State Medical Association.—Dr. P. H. Stewart, of Paducah, was elected president of this association, at the annual meeting held in Hopkinsville, October 26th and 27th, and other officers were elected as follows: Dr. L. P. Earle, of Charleston, first vice-president; Dr. A. S. Brady, of Greenup, second vice-president; Dr. J. G. Gaither, of Hopkinsville, third vice-president; councillors, Dr. J. W. Kinkead, of Catlettsburg; Dr. J. N. McCormack, of Bowling Green; Dr. R. C. McChord, of Lebanon; orator in medicine, Dr. Sidney J. Meyers, of Louisville; orator in surgery, Dr. Fred L. Koontz, of Louisville. Next year's meeting will be held in Ashland. Important features of the scientific program were papers by Dr. Joseph C. Bloodgood, of Johns Hopkins University, and Dr. C. C. Bass, of Tulane University.

The Abolition of Heroine.—A meeting of the Committee on Drug Addiction of the National Committee on Prisons was held at the Hotel Vanderbilt last week, with Dr. Simon Baruch in the chair. Among those present were Dr. Samuel W. Lambert, Dr. Frederick Peterson, Dr. Charles F. Stokes, formerly surgeon general of the United States Navy; Mrs. Helen Hartlet Jenkins, Mr. Frederick Tilney, chairman of the Committee on Social Hygiene, and Mr. Joseph D. Sears, secretary ex officio. Discussion of the subject of drug addiction showed the consensus to be that among drug addicts the heroine habit was most prevalent among boys and in the early decades of adult life, and therefore the chief promoter of vice and crime. In view of this fact resolutions were adopted stating that since heroine was not so indispensable a drug that its place could not be easily filled by other drugs and measures that did not menace public welfare, it was recommended that Federal legislation be enacted to prevent the importation, manufacture, and sale of heroine.

Southern Medical Association.—The tenth annual meeting of this association will be held in Atlanta, Ga., November 13th to 16th, under the presidency of Dr. Robert Wilson, Jr., of Charleston, S. C. Dr. Holman Taylor, of Fort Worth, Texas, and Dr. Guy L. Hunner, of Baltimore, are vice-presidents of the association, and Dr. Seale Harris, of Birmingham, Ala., is secretary-treasurer. An excellent program has been prepared, and the meeting gives promise of being unusually interesting. On Monday, November 13th, the Southern States Association of Railway Surgeons, which is an auxiliary of the Southern Medical Association, will hold its fourth annual meeting under the presidency of Dr. Southgate Leigh, of Norfolk, Va. On Monday evening there will be a public meeting, at which Dr. W. A. Evans, of Chicago, will deliver an address on Infantile Paralysis, which will be followde by a concert. On Tuesday morning, at a general session, the annual presidential address will be delivered by Doctor Wilson, his subject being Opportunities and Responsibilities. Other addresses to be delivered at this session are the Oration in Medicine, by Dr. M. L. Graves, of Galveston, Texas, Cui Bono; the Oration in Surgery, by Dr. W. D. Haggard, of Nashville, Tenn., on Surgery of the Stomach; Medical Preparedness in the Army, by Major Robert E. Noble, U. S. Army; The Doctor's Work for National Defense, by Dr. Cary T. Grayson, of Washington, D. C. Surgeon General Rupert Blue, United States Public Health Service, is expected to deliver an address at this session. An attractive program of entertainments has been arranged by the local committee, which includes alumni reunions, receptions, automobile rides, etc. On Tuesday evening, the annual banquet of the Southern Medical Women will be held at the Hotel Piedmont, to be followed by a business meeting.

Combating Insects Which Affect the Health of Man.—Continued advances in the work of combating the activities of insects which affect the health of man are reported by the chief of the Bureau of Entomology of the United States Department of Agriculture in his annual report recently issued. In mosquito investigations in Louisiana a species hitherto considered a noncarrier of malarial infection was proved to be a carrier. Studies have been made of malaria, and measures are being evolved to meet plantation conditions. The "starvation" plan, aimed at exterminating the spotted fever tick of the Bitter Root Valley, Montana, was followed. The bureau also conducted a campaign of extermination against ground squirrels and other rodent hosts of the immature ticks. Examination of the rodents killed showed forty per cent. lower infestation by the tick than during the preceding year. The report directs attention to the demonstrations of the bureau specialists that the breeding of flies in manure can be prevented by treating the substance with calcium cyanamide and acid phosphate.

Prevention and Relief of Heart Disease.—At the last meeting of the Board of Governors of the Committee for the Prevention and Relief of Heart Disease, plans were developed for an active campaign to arouse public interest in the important problems of heart disease. The work was placed in the hands of special committees dealing with various phases of the problem, and the following program has been outlined by the Committee on Relief:

First: Occupation for Cardiacs—the Main Problem in Relief: (a) School children; vocational guidance, early selection of suitable occupations, etc. (b) Adults; under supervision of Social Service, mainly: 1. Adapting present occupation to the physical requirements of the patient. 2. Changing occupation. 3. Teaching a new occupation. 4. Establishing of the patient in a small self supporting business.

Second Cardiac Classes: To be established in connection with hospitals when possible with duties divided into medical and social work.

Medical Service to cover: 1. Constant supervision of the patients. 2. Diagnosis of heart disease. 3. Estimation of cardiac efficiency. 4. Examination of applicants for convalescent homes. 5. Assistance in the selection of suitable occupations.

Cardiac social service includes: 1. Referring patient to the clinic. 2. Follow-up of hospital, dispensary and convalescent cases. 3. Study of occupations, and placing therein. 4. Home convalescence and betterment of home hygiene and conditions. 5. Temporary financial aid.

Third: More Opportunity for Cardiacs in Convalescent Institutions: Fourth: Permanent Institutional Care: Large numbers of cardiacs, known as third stage cases, have repeated breaks in compensation and possess little or no economic value to the community. About fifty per cent. of their time is spent in hospitals and the remainder in losing the slight gains thus made. They are too chronic for the hospital, too serious for ambulatory treatment in cardiac classes or dispensary, too uncertain for the convalescent home. They are fit only for permanent institutional care.

Some economic values are often latent in these persons if suitable occupations are provided within the institution, with sales outlet for the produce arranged. Such institution could never be more than partially self supporting.

Dr. Frederic Brush is chairman of the Committee on Relief and the other members are Dr. Hubert W. Guile, Mr. Morris Waldman, and Mr. Charles Burlingham.

In addition to the foregoing, it is hoped that a way may be found to keep all the public playgrounds opened the year around. Heretofore some of these playgrounds have been closed during the winter.

The committee's program is of special interest now that public attention is focused on the aftercare of poliomyelitis. For the latter, as our readers know, funds have been forthcoming from many different sources. As a matter of fact, the problem presented by the proper care of cardiac cases is the most important of the two. It is estimated that there are about 20,000 children alone suffering from heart disease and requiring systematic care. In a number of ways the two groups need similar provision for relief. Thus both groups should be under constant social and medical supervision; the members of both groups should be fitted for occupations suited to their infirmity; some of the children in both groups need to be taken to school in conveyances. Altogether, it would seem likely that a similar plan of procedure would be developed, especially that a way be found to coordinate the work of existing agencies to the fullest extent.

The committee is appealing for funds to carry on its work. Those interested can obtain further information by writing to the Executive Secretary, Miss H. L. Woughter, 340 East Twenty-sixth street, Manhattan.

Modern Treatment and Preventive Medicine

A Compendium of Therapeutics and Prophylaxis, Original and Adapted

THE THERAPEUTICS OF A PHARMACOLOGIST.

By A. D. Bush, M. D.,
Professor of Pharmacology and Therapeutics, University of Southern California.

Forty-third Communication.

TONSILLITIS.

When those outposts of the body, the tonsils, become invaded by the enemy, there is great danger of distant trouble sooner or later. The avenues from the tonsils to remote areas seem especially open to some bacteria, particularly to those of the streptococcic family; so it behooves the attending physician to take unusually active measures, particularly so now that the streptococcic variety of tonsillitis seems to be spreading rapidly.

A prime essential is not to borrow unnecessarily of nature's reserve combative power; to this end the patient is put to bed and kept as quiet as possible. Because of the abnormal susceptibility of the lithemic to tonsillitis and pharyngitis, it is well to make tentative use of the salicylates in suspected cases of rheumatic predisposition. We may freely acknowledge ignorance of how the salicylates may be of value in rheumatism, contenting ourselves for the present with the clinician's assurance of demonstrated utility.

For local application no one thing is so generally sedative as a mildly alkaline solution, such as normal saline with borax or soda, frequently applied by spray or gargle; beside being cleansing, the alkalinity seems to soothe and favor resistance. Not infrequently the immediate relief is accentuated by using the gargle as hot as can be borne, the heat producing a relaxing effect, tending to favor resolution. A somewhat opposite method of attack is the application of astringent solutions, such as tincture of iron perchloride, and weak solutions of silver nitrate. Beside constringing the superficial tissues and thereby exerting some pressure on the deeper structures, these solutions enter the crypts and follicles to some extent and serve as deterrants to bacterial activity. Both of these preparations are best administered by swabbing applications; great care must be exercised that no liquid trickles down into the larynx, as the nitrate solution, especially, will produce glottic spasm of a very distressing character. Probably antiseptic applications have very little local effect, as the invading organisms are too deeply lodged to be thus affected, but it is not impossible that the contiguous mucosa is partially protected by these means.

Many physicians lay claim to good results from the internal administration of full doses of iron, especially the citrate of iron and quinine, but it does not appear pharmacologically wherein this treatment would exert any beneficial influence. If it helps to restore the disturbed organism to a normal state, it is a reasonable procedure, but has it been proved that the hemin content of the blood is reduced or that the plasmodia of malaria are present in tonsillitis? If not, then some other reason must be assigned for the alleged value of these substances; and while they may act favorably in some as yet undetermined manner, we must be sure that such is the case, before trusting our deductions.

Perhaps the most rational line of treatment is the prompt preparation of an opsonic autoserum and the administration of this to the patient, thereby assisting nature to a more efficient manufacture of those antibodies without which no cure is possible. Too often we are prone to forget that the development of antitoxins is nature's method of effecting cures; that drugs are but accessories, and care must be taken that they do not become impediments.

MERCURY PROTIODIDE.

One Half Grain, Four Times Daily.

By Charles C. Miller, M. D.,
Chicago.

Most syphilitics treated with mercury in this country receive the drug in the form of the protiodide by the mouth. I shall not enter into the discussion of the value of mercury in the treatment of specific disease, yet few physicians are entirely satisfied with its action in the alimentary canal.

Take a syphilitic, give him mercury protiodide and almost certainly he will become constipated. Sooner or later he has a foul breath, more or less gastric disturbance, and anemia. Sometimes too there is considerable acneform eruption.

To avoid these disadvantages, and secure a more pronounced effect, the writer has for years used the following method with distinct success: Once I am sure of the diagnosis, the patient is put upon one half grain protiodide of mercury tablets *before* meals and at bedtime. Just as soon as the protiodide tablets are started, laxatives are given.

Ordinarily a syphilitic taking this dose will require one half grain of podophyllin every night at bedtime. This is given in the form of one quarter grain tablets. A few patients require only one and others as many as three. If Hinkle's formula is used, one, two, or three must be given every night. This is not to purge; the patient should not be purged. The laxative is regulated to assure one or two stools daily. Without the laxatives the patients will quickly become constipated and then salivated.

Observing these rules, giving the protiodide before meals, and keeping the bowels open, the writer has, during the past fifteen years, treated many syphilitics, keeping them continuously upon two grains of protiodide each day for periods ranging from six months to a year; this, too, without unpleasant symptoms.

The effectiveness of protiodide given in this way will, I believe, astonish many physicians who have failed to get results in syphilitic infections.

32 North State Street.

A New Alcohol Tooth Paste.—Theodor Sachs (*Medizinische Klinik,* Sept. 17, 1916) states that in the treatment of mercurial stomatitis the desideratum is to employ a preparation which will act chiefly upon the gums. For this purpose the author has elaborated a tooth paste which consists essentially of an alcohol soap to which are added the usual bleaching and flavoring agents of tooth pastes. This new preparation brings the alcohol into direct contact with the gums where it can exert its mildly tanning and astringent powers. The preparation can be employed in the same way as the ordinary tooth pastes and produces an effective cleansing lather.

Fecal Stasis and Eczema madidans.—W. H. Axtell (*Northwest Medicine.* October, 1916) states that among the many distressing conditions secondary to fecal stasis and angulation of the sigmoid is chronic, weeping eczema. From an experience of eight cases of this obstinate skin lesion the author finds that it can be cured promptly by treatment directed to the relief of the intestinal disturbance. This treatment consists in the use of daily enemas, mild laxatives, and a regulated diet. Through the sigmoidoscope the sigmoid should be inflated and elevated, and any ulcerations of its mucosa treated by direct applications. Under such treatment the "weeping" will stop within two days and the eczema will be completely cured in two weeks. All local treatment of the eczema should be stopped except hot water fomentations where there is skin infection.

Treatment of Goitre with Quinine and Urea Injections.—L. F. Watson (*Texas Medical Journal,* October, 1916) uses the injections merely to relieve the symptoms of hyperthyroidism and they are not recommended to remove the tumor in simple goitre. The injections should always be made within the thyroid so that there will be no adhesions around the gland and operation will not be made more difficult because of previous treatment. Small infiltrations, often repeated, are to be preferred to massive ones. The injection of a weak solution of quinine and urea has little effect and the injection of concentrated solutions always gives rise to necrosis and connective tissue formation. The injections of iodine, carbolic acid, alcohol, arsenic, iodoform, and chromic acid are to be condemned because of their poisonous and corrosive properties, and the danger of producing a thrombus if accidentally injected directly into the vein. In treating toxic goitre it is necessary to prevent the pain due to injection by local anesthesia. If acute attacks of hyperthyroidism are to be prevented preliminary injections into the most prominent portion of the goitre of a few minims of sterile salt solution, given at one to three day intervals, followed by injections of sterile water, will be found indispensable. The result of quinine and urea injections depends on the amount of tissue destroyed. The cases that respond best to quinine and urea injections are those of beginning hyperthyroidism not severe enough to justify operative treatment, and as a preparatory measure to partial thyroidectomy in chronic cases of goitre too severe to warrant any immediate operative procedure.

Fissure of the Anus.—Charles J. Drueck (*International Journal of Surgery,* October, 1916) states that there are two principles governing the treatment of fissure: Rest and drainage. The bowels should be kept open—if possible by dieting or with enemas of olive oil or glycerin suppositories. Laxatives are contraindicated. In recent fissures, before the wound edges are thickened, the anus, and, if possible, the ulcer, is sprayed with a four per cent. solution of cocaine in one to 1,000 adrenaline chloride solution allowed to remain five minutes. A conical fenestrated speculum is now inserted with a shutter over the fissure. The shutter is withdrawn and the speculum opened, bringing the fissure into view. It is sprayed with cocaine if not previously reached, and painted with silver nitrate solution, twenty grains to the ounce, or with pure ichthyol. A cure should be effected in from two to four weeks If not obtained within this time surgical treatment should be tried. Divulsion of the sphincter is an old method which gives good results at times. Incision with drainage produces better results and may be performed under local anesthesia unless the patient is very nervous or the sphincter particularly irritable.

Preoperative Considerations in Exophthalmic Goitre.—D. M. Berkman (*St. Paul Medical Journal,* October, 1916) asserts that of the medical measures other than rest applied in exophthalmic goitre, e. g., bromides, phosphorus preparations, belladonna, and quinine, serum of thyroidectomized animals, Beebe's cytolytic serum, x ray exposures with the Coolidge tube, etc., the x ray probably produces the most decided results. Practically no benefit is obtained from it, however, in less than a month, and in the severe cases, the attendant excitement and mobilization usually offset the benefit. Digitalis is of value in the cases in which prostration is due to secondary cardiac deficiency. Porter's hot water injection entails practically no risk and often yields immediate improvement. One death has followed such an injection at the Mayo clinic, but the case was one of extreme intoxication, recovery from which seemed impossible. The hot water injection is a fairly accurate indication of the ability of the patient to undergo surgical treatment of the thyroid. In the occasional cases in which but little improvement results from a period of rest in bed, the patients are sometimes sent home from the Mayo clinic to continue the rest treatment; these patients usually return after several months in a condition permitting the operation of ligation with safety. The operative mortality at the Mayo clinic for the successive years, 1910 to 1915, was 4.8, 3.18, 2.6, 3, 2.89, and 2.63 per cent., respectively. The cases included were all instances of unmistakable hyperthyroidism. In the twenty-four fatal cases recorded in 1914 and 1915 the duration of previous definite history of the disorder was observed to have little bearing on the operative risk, though according to Mayo, it is in the rather acute cases, with special lethal tendency in the latter half of the first year, when the most marked effects are shown in the heart, liver, kidneys, and nervous system, that the operative mortality is highest.

Treatment of Graves's Disease by the Röntgen Ray.—Malcolm Seymour (*Boston Medical and Surgical Journal,* October 26, 1916) says that all writers on the subject of x ray treatment of hyperthyroidism have come to the following conclusions: The pulse rate is nearly always reduced, and this almost at once. The tremor and nervous symptoms improve from the start. The gland rapidly diminishes in size in some cases, remains unaffected in others, but if hard, tense, and throbbing, the throbbing diminishes and the gland becomes softer. The body weight practically always immediately increases. The advantages alleged for this treatment are: 1, There are no fatalities. 2, There is no resulting scar, as after operation. 3, It does not interfere with the patient's occupation. 4, It is painless and causes very little inconvenience to the patient. 5, If unsuccessful, an operation may be done with less risk, because of the favorable action of the x ray on the thymus gland. The x ray treatment of Graves's disease should not be undertaken except by those who are thoroughly experienced in Röntgen therapy. The dose must be accurately measured, for if the rays are applied in a haphazard manner without knowledge of the total dose, the result may be unsatisfactory, resulting in serious burns, or in total destruction of the gland, causing myxedema. The diagnosis of hyperthyroidism is frequently overlooked, and is mistaken for socalled neurasthenia, and is especially confounded with early pulmonary tuberculosis.

Mineral Water Injections in the Treatment of Boardlike Edema.—Denis (*Presse médicale,* September 7, 1916), having personally been relieved of annoying local sequelæ of acute rheumatism by Breuil mineral water, conceived the idea of applying the same water, chiefly by subcutaneous injection and in some cases by mouth, in the treatment of similar conditions of the tissues following wounds. The method was applied in nearly one hundred cases, a total of over two thousand injections being administered. The mineral water in question is classed with the sodium bicarbonate ferruginous waters, and is obtained commercially in 125 gram bottles. The dose for subcutaneous use was two small hypodermic syringefuls, taken directly from the bottle without previous sterilization of the water, which seems to be free of bacteria, no abscess ever resulting. The patient then was sometimes given the remainder of the bottle by mouth on an empty stomach, and another bottle later in the day. No other treatment was employed. The results were in most instances unexpectedly excellent. Obstinate, hard edema of the leg or arm following fractures, with trophoneurotic changes, or following phlebitis of the phlegmasia alba type, disappeared with surprising rapidity under the treatment. Superficial circulatory disturbances, when present, were first to disappear. Removal of hard periarticular edema permitted of more accurate x ray work, early mobilization, and electrotherapy, thus preventing stiffness or ankylosis, nerve degeneration, and muscular atrophy. Care was taken in the use of the water in patients with high blood pressure or fatigued circulation, on account of the pronounced action of the water on the latter. It is possible that other similar mineral waters may yield like results.

Röntgen Ray Treatment of Exophthalmic Goitre.—C. Augustus Simpson (*Southern Medical Journal,* October, 1916) concludes that x raying the thyroid gland alone will sometimes relieve the symptoms of Graves's disease. The blood count, fluoroscopic, and x ray picture examinations are often misleading and should not have too much effect on prognosticating the favorable and unfavorable cases. A large percentage of cases of exophthalmic goitre is associated with enlarged thymus, which many surgeons, to avoid dangerous postoperative symptoms and even death, advise resecting at the same time the thyroid is removed. This must greatly prolong and complicate the difficult operation of thyroidectomy in patients whom we have always regarded as bad operative risks. The Röntgen ray will quickly and painlessly atrophy the thymus gland, and for this reason should be the method of choice in all cases of exophthalmic goitre where enlarged thymus is suspected.

Treatment of Intestinal Stasis.—Fred M. Hodges (*Charlotte Medical Journal,* October, 1916) says that in the dietetic treatment the patient should be advised to drink plenty of water and eat bulky foods, especially cereals containing a great deal of organic acid and cellulose. Two important hygienic measures are the habit of going to stool at a certain time every day, and physical exercise. Massage is of value in a few cases and in a few electricity may be helpful. Medicinally, alkalies should be given where it is known that hyperacidosis exists. For marked constipation a mercurial, preferably blue mass in five to eight grain doses should be given every week or ten days. Agar, combined with cascara or phenolphthalein given twice daily in one to two dram doses is the best treatment if a laxative is to be used for a prolonged period. In some cases an insufficiency of the ileocecal valve is shown by the x ray and occasionally tenderness will be found during the examination when the ordinary examination was negative. Removal of the appendix has helped the treatment for stasis in these cases.

Resistance of Bacteria and Human Tissues to Germicides.—Robert A. Lambert (*Journal A. M. A.*, Oct. 28, 1916) reports the comparative resistance of living human cells and of Staphylococcus aureus to several germicidal substances determined by means of an improved technic for the artificial cultivation of living tissues. The germicides used were mercuric chloride, potassiomercuric iodide, potassium cyanide, sodium hypochlorite, iodine, phenol, tricresol, argyrol, hydrogen peroxide, and alcohol. Iodine alone proved relatively more destructive to the bacteria than to the tissue cells. The difference in destructive effects upon the bacteria and tissue cells was not great in the case of several other germicides, but they were all relatively more destructive to the tissue cells than to the bacteria. No ideal germicide in the sense of their relative differences was found among those employed, for iodine had the disadvantage of dissolving fibrin, which forms the scaffolding in wounds along which new cells grow. A striking fact was also shown, namely that hydrogen peroxide was an extremely feeble germicide although it was relatively very destructive to the tissue cells.

Treatment of Wounds with Possible Injury of Large Vessels.—E. Potherat (*Presse médicale,* September 7, 1916) comments on the frequency with which unsuspected wounds of large vessels in the neck and extremities are found, in spite of previous absence of hemorrhage, when dressings are being applied, or suppuration or absorption of a clot occurs. Fatal hemorrhage may occur in this way in a few hours, days, or weeks after the injury. Such cases are so numerous that Potherat is led to recommend, in all wounds in which, from the point of entrance or course of the missile, the latter must plainly have passed through a group of vessels and nerves or near a large vascular trunk, that we assume that vascular injury has taken place, even if hemorrhage is slight or absent. The vessel should be plainly exposed and if necessary ligated.

Thrombosis of the Brachial Artery.—John A. Caldwell (*Journal A. M. A.,* Oct. 28, 1916) reports a patient who sustained an injury to his brachial artery which produced thrombosis almost at once. Within a few hours after the accident the artery was exposed through an incision and traced downward to the point at which expansile pulsation disappeared. From this point down it was gently massaged with stroking made from below upward. After a few strokes pulsation appeared in the radial. After waiting for several hours, at the end of which time the radial pulse was still vigorous, the wound was closed and the patient made a complete recovery. This treatment apparently broke up the thrombus or caused its solution. Such treatment is applicable only where the thrombus is situated above a region in which there is an abundant collateral circulation, where there is little danger of an embolus being carried to the vital organs, where it can be carried out very promptly after the injury, and where the injury to the intima of the vessel is not very great. Under other conditions the best treatment is incision and thrombectomy with suture of the vessel.

Causes and Prevention of Untoward Results Following Use of Arsenobenzol Compounds.—J. Danysz (*Presse médicale,* September 14, 1916) states, as a result of experimental investigations, that thrombosis and phlebitis at the point of injection may occur, not only from faulty technic, but from excessive alkalinity of the solution used. Vomiting, diarrhea, chills, headache, and temporary fever occur within a few minutes or hours after an injection. Milan's "nitritoid attacks," are due to vasodilatation and also to the formation of a precipitate which is arrested temporarily in the capillaries. The promptness and severity of these effects depend upon the amount and concentration of drug given. A sufficiency of alkali with the drug will prevent them in persons with normal blood composition. Formation of precipitates is favored by presence in the menstruum of sodium chloride and especially of phosphates, carbonates, sulphates, oxalates, and magnesium chloride; on the other hand, it is lessened, thus diminishing the severity of nitritoid or anaphylactic aftereffects, by slow administration of very dilute solutions, by preparing these diluted solutions with isotonic sugar or glycerin solution, and by simultaneously injecting anesthetics or vasoconstrictors. The neutral drugs of this group, such as neoarsenobenzol, do not precipitate in the presence of chlorides, sulphates, or carbonates, and thus only exceptionally cause early untoward effects; more serious late results, however, are produced oftener than with the alkalinized compounds, such as arsenobenzol. With the whole group of these drugs, formation of a nonnoxious or slightly noxious precipitate is an essential condition for therapeutic efficiency. The sodium combined products are thus more active than the neutral (neo) ones, and when well prepared and injected with the required precautions, they are less dangerous than the latter.

Syphilis of the Central Nervous System.—A. Rocke Robertson (*Brit. Med. Jour.,* October 7, 1916) emphasises the fact that the spirochetes enter the meninges and nervous tissues early in the disease, there to produce lesions which are chiefly vascular and meningeal at first, later becoming largely avascular and degenerative. Since the cerebrospinal fluid is a true secretion into which few drugs pass it is necessary to introduce antisyphilitic agents directly into the fluid. This is best accomplished by the method of Swift and Ellis or by the use of serum to which definite small quantities of neosalvarsan have been added *in vitro*. The latter is the preferable method. Even in early syphilitic infection it is usually not enough to apply systemic treatment alone, for many such cases will later show manifestations of syphilis of the central nervous system. Robertson has secured very satisfactory results, both clinically and as judged by the Wassermann and other tests applied to the blood and spinal fluid, by the use of combined treatment in cases with early symptoms of involvement of the central nervous system. Early tabetic symptoms, headaches, and ocular changes were totally checked or largely removed. His plan was to give repeated intravenous doses of neosalvarsan and repeated intraspinal injections of autosalvarsanized serum. The repeated practice of combined injections gave better results than the use of either method alone.

Treatment of Grippe in Children.—Lawrence T. Royster (*Journal A. M. A.,* Oct. 28, 1916) states that prophylaxis is the most important of all the features of treatment, especially in infants and young children. Any member of the household who has grippe should be kept from the younger members, and this is true even in the case of "colds" which may be grippe in mild form. Nursing mothers with grippe should keep their mouths and noses covered with handkerchiefs when nursing or attending their babies, and other attendants who come into close contact with infants should adopt the same practice. Crowded places should be avoided and the children kept in the open air except when there is very much dust. When the child has grippe the main reliance should be placed upon sodium salicylate after an initial purgative and an initial dose of Dover's powder. The child should be kept in bed no matter how mild the attack; and symptomatic remedies exhibited as needed, chiefly opium for severe pains and aching. Nasal drops of menthol and camphor in petrolatum are useful

in the catarrhal forms. For cough wine of ipecac is useful in the tight stage followed by ammonium chloride and the adoption of general treatment suitable for pneumonia. Opium may be necessary for very severe racking cough. In the gastric type with vomiting the child must be kept absolutely quiet, allowed nothing by month, and the bowels kept open by enemas. Where there is diarrhea the colon should be irrigated, small doses of salines given, and a carbohydrate diet prescribed. Cardiac arrhythmia demands absolute and prolonged rest and occasionally digitalis. Otitis calls for the usual treatment with early incision of the drum membrane. Where there is persistent cough the child should be kept in the fresh air, prescribed regular and frequent periods of rest, and given tonics such as codliver oil. The disease should be quarantined.

Picric Acid in the Treatment of Erysipelas.—D. Critzman (*Presse médicale,* September 11, 1916) reports excellent results from applications of picric acid solution in both facial erysipelas and in erysipelas complicating wounds. The solution used is one in 1,000, with twelve grams of alcohol added to a litre of solution. As soon as the diagnosis is made, the affected area and zone surrounding it are painted with the solution, and a dry cotton dressing is applied. This is repeated every twelve hours thereafter. In three days, as a rule, the eruption is checked and the general condition improved, with a rapid drop in temperature. In cases treated less early benefit is likewise obtained, a prompt detergent action being exerted on the phlyctenular eruption, the duration of which is shortened. In no case was there noted a recrudescence of the local infection prolonging the disease more than twenty days. In surgical erysipelas, often migrating to the trunk or limbs, whatever the point of origin of infection, Critzman was always able to prevent extensions of the diseased area. Among weakened and cachectic patients, in whom erysipelas is often fatal, he had no deaths. He warns against the use of phenol sprays in erysipelas, considerable absorption taking place from the affected surface.

Autogenous Bacterial Vaccines in the Treatment of Bronchitis.—J. E. Robinson and D. W. Queen (*Southern Medical Journal,* October, 1916) speak highly of the effects produced by autogenous vaccines in simple bronchial catarrh and are inclined to believe that they are beneficial also in pulmonary tuberculosis, where the condition is not acute and where symptoms due to a secondary infection are pronounced. A stopping or diminution of the cough and expectoration, and the controlling of the temperature, if only for a few months, would be a material factor in the ultimate cure of the patient, and during the few months of an active immunity the general health of the patient may be brought to a high standard by rest, dietetic, and hygienic means. The vaccine is made to contain one thousand millions of bacteria per c. c., so each 0.1 c. c. represents one hundred millions of bacteria. Roughly speaking, 0.1 c. c. equals two minims. The first dose is generally 0.2 to 0.3 c. c., and may be repeated in from five to ten days, increasing 0.1 to 0.2 c. c. each dose, depending on the reaction secured from the previous one. Reactions are of two kinds, local and general. The local reaction consists of a redness and swelling at the point of inoculation, which should be about two or two and a half inches in diameter and should last two or three days, with some tenderness. The general reaction is a feeling of malaise with an increased cough and expectoration with a rise of temperature. If fever is produced, or if the local reaction is greater than two and a half inches, the dose is excessive, and should not be increased, but may need to be reduced.

Cranial Decompression in Spastic Cerebral Paralysis.—William Sharpe (*N. Y. State Jour. Med.,* October, 1916) classifies cases of cerebral spastic paralysis into the group without evidences of increased intracranial pressure and that in which there are evidences of such a condition. The latter type is the one which is amenable to operation with some hope of benefit. An experience of 219 cases falling in the second category has shown that decided benefit may be expected from a decompression operation. The improvement is manifest in diminution of the paralysis and spasticity, in the associated symptoms of convulsions and epileptiform seizures and in the improved mental development of the children. The operation consists in trephining and making a fairly large opening through the skull beneath one or both temporal muscles, combined with stellate incision of the dura. If there is a blood clot or if cysts are present these should be drained away, but scar tissue should be left undisturbed. The operation is simple for one experienced in brain surgery and is not fraught with danger to life. The technic is fully described. After the operation the usual orthopedic measures and proper muscle training should be instituted. The earlier in the course of the condition the operation is performed the better will be the results, and in a few cases operation has been performed with perfect results shortly after birth in cases in which traumatic hemorrhage was suspected.

Amputation Through Infected Tissues.—Chaput (*Presse médicale,* September 21, 1916) calls attention to the advantages of "lamellar" drainage in dealing with stumps resulting from amputation through infected tissues. This procedure consists in the use of sheets of rubber for drainage so arranged as to insure free vertical outflow of the wound secretions. Two conditions, however, are essential, viz., that in amputating, the flaps should be made of equal length and long enough to be easily sutured, and that they should not bear any gangrenous lesions. The flaps should, if possible, be lateral ones, as with anteroposterior flaps we cannot secure vertical drainage with the patient recumbent—unless he lies on the side, which is not always convenient or possible. At the inferior margin of each flap three pieces of silkworm gut are tied, one at each angle and a third at the centre of the free margin. With forceps one or more sterile sheets of rubber, one to three fingerbreadths wide, are next introduced so as to separate completely the internal surfaces of the two flaps from each other. The rubber should project two fingerbreadths beyond the wound margins, and a safety pin passed through the end.

Miscellany from Home and Foreign Journals

Shell Shock.—Arthur v. Sarbo (*Medizinische Klinik*, September 17, 1916) states that in a proportion of cases of shell shock there is actual damage to the medullary centres and specially to those of the eighth, ninth, tenth and twelfth nerves, leading to deafness and loss of the power of speech. The damage is believed to be due to the driving of the medulla into the foramen magnum, and of the cerebrospinal fluid into the fourth ventricle. In addition the shock may cause a disturbance of the circulation through the medulla. In certain other cases there is fracture of the base of the skull which is the cause of the symptoms. In a large proportion of the cases recovery is complete and in some the return of speech is sudden, though this is not the rule.

Breathlessness in Cases with Irritable Heart.—Thomas Lewis (*Brit. Med. Jour.*, October 14, 1916) states that from a study of a large group, several cases were found in which the breathlessness could not be attributed to the usual factors such as acidosis and respiratory or circulatory embarrassment. In these cases there was found to be a relative deficiency in the "buffer" salts of the blood so that when all of the contained carbon dioxide was shaken out the blood was more alkaline than normal blood. In the presence of the normal content of carbon dioxide the blood was just on the acid side of normal and an additional amount of carbon dioxide produced an abnormal increase in the blood's acidity. These results were confirmed by the electrometric determination of the hydrogen ion concentration and the relative absence of the "buffer" salts was proved by the addition of very small amounts of them to samples of the blood, and retesting the reactions.

Value of the Widal Test in Typhoid and Paratyphoid Fevers among the Vaccinated and Unvaccinated.—C. Gautier and R. J. Weissenbach (*Presse médicale*, September 21, 1916) refer to the fact that the value of the Widal agglutination test has been called into question owing to the frequency with which agglutinins for not only the typhoid but also the paratyphoid organisms are found in the blood in typhoid fever and the further complication entailed through previous protective inoculation. They report clinical laboratory work in 226 cases, including sixty-six controls and 160 cases of typhoid or paratyphoid infections confirmed by blood culture. Certain precautions in the test must be taken, if its diagnostic value is to be retained. The strains of organisms used must always be the same, and should possess an elective, high, and fixed aptitude for agglutination. A saline emulsion of a twenty-four hour agar culture is used, with 0.1 c. c. of commercial formaldehyde solution added to every fifteen c. c., and a constant titre of 350 million bacilli per c. c. The highest dilution yielding agglutination is that in which small flakes are visible with the naked eye after four hours' incubation. This highest dilution should always be ascertained, not only for the typhoid but also the A and B paratyphoid bacilli. If two or all three of these germs are agglutinated, and the ratio of their highest dilutions is one to six, seven, or more, that agglutinating in the higher dilution may be considered the infecting germ in the particular case. If the ratio is one to five, four, or less, the agglutinin saturation test must in addition be resorted to, i. e., each organism must be added in turn to a separate sample of the serum until that one is found which, upon such addition, causes agglutinating power to disappear, not only for its own species, but also for the other bacterial species in question. This organism is the one responsible in the given case. Furthermore, in unvaccinated subjects, the agglutination test, before the fifteenth, and especially before the eighth day of the disease, when the highest dilution is at least one in thirty for the typhoid and A paratyphoid organisms, or one in fifty for the B paratyphoid; after the fifteenth day these ratios are changed to one in fifty and one in 100, respectively. In subjects vaccinated against typhoid alone at least two months before, the test is available and positive at similar limits, specified in the article. In subjects vaccinated less than two months before, the test is valueless from the typhoid standpoint, though available for the other two organisms, against which the patient has not been protected.

Epidemiological and Clinical Considerations on Typhus Fever in Serbia.—Pétrovitch (*Bulletin de l'Académie de médecine*, September 19, 1916) points out that, in September, 1914, the typhus epidemic in Serbia was an obscure one, the early cases often being those of subjects already suffering from other infections and usually discovered in typhoid wards in hospitals. During this latent period the typhus infection was evidently being gradually distributed among the lice, the latter finally giving rise, from December, 1914, to July, 1915, to the gravest typhus epidemic ever known in Europe. By March, 1915, no hamlet in the entire region was free of the disease. Only 350 physicians and surgeons being at hand for a civil and military population of four millions, sanitary measures could not be adequately carried out. Foreign medical missions, however, aiming exclusively at destruction of lice, greatly reduced the epidemic in a short time. Later, during the retreat to Albania, it returned, but both morbidity and mortality were lower than in the earlier outburst. Pétrovitch comments on the necessity for early detection of the disease by closely watching among the typhoid patients for photophobia; facial turgescence; a diffuse, sombre redness, with rose colored points of the velum palati and uvula, and a coated, red margined tongue, followed by extreme dryness and tumefaction of this organ. Cleansing the arms with soap and water facilitates early detection of the eruption. These suspicious symptoms begin on the second day and indicate immediate isolation, before the eruption has become characteristic. A pulse rate of 100 to 120 from the outset, with marked softness and compressibility and obscurity of the heart sounds, portends early collapse, with death from circulatory failure.

Death Rate in Acute Infections.—Edwin E. Graham (*Journal A. M. A.*, October 28, 1916) reports that the deaths in Philadelphia from the acute infections occurring during the last five years have been analyzed and showed that of the five diseases, scarlet fever, measles, diphtheria, whooping cough, and typhoid fever, diphtheria caused the largest total number of deaths with typhoid, measles, pertussis, and scarlet following in the order given. The figures included all ages up to twenty years. In regard to prevalence measles led with a great majority and was followed in order by diphtheria, scarlet, whooping cough, and typhoid. Typhoid showed the highest death rate and measles the lowest with the others falling between. Whooping cough caused the largest number of deaths in infants less than one year old with measles second. Diphtheria caused the largest number during the second year, and this was also the period of highest death rate from measles. Diphtheria led in total number of deaths in the age periods from two to five and five to ten years with scarlet fever second for both periods. Typhoid fever was lowest up to five years and then rose with each five year period to the highest death rate for all periods over ten years. From ten to fifteen years diphtheria was the second most fatal of these diseases, scarlet third, and pertussis practically without fatality. The mortality from scarlet, however, was extremely low during and after this age period. For the total period of five years and including all ages up to twenty years scarlet fever caused the fewest total number of deaths, with pertussis second.

Differential Diagnosis of Exophthalmic Goitre.—A. W. Plummer (*St. Paul Medical Journal*, October, 1916) discusses in particular the differentiation of exophthalmic goitre from neurasthenia, the condition with which it is oftenest confounded. The picture of exophthalmic goitre is so definite a one that where the symptom group does not closely correspond, suspicion of another condition is warranted. A pulse rate of 120 associated with cold dry hands at once practically excludes hyperthyroidism. Marked fluctuations in the severity of the symptoms are typical of this condition, but they differ from those of neurasthenia in that their wave length as a whole is measured in weeks or months instead of in hours or days. The wave is often topped by a crisis of aggravation in all the nervous symptoms, together with anorexia, diarrhea, and painless vomiting. Too much stress is often laid on nervousness, palpitation, and tachycardia as diagnostic features, as they occur in many other conditions. An increased appetite, though it may be lost for short periods and often goes unnoticed, is the most reliable single symptom, in particular when it is associated with loss of weight. Polydipsia may also be present. A sensation of heat, usually with hyperhidrosis, is characteristic, but must not be confounded with the transitory hot flushes and cold sweats of neurasthenia. Thinning of the hair, general pruritus, and periods of scanty menstruation are also significant. A tight or choking sensation at the throat, without sufficient obstruction from the goitre, suggests neurosis. The nervously stimulated type of neurasthenia may simulate exophthalmic goitre, but the facies of the patient is missing, and one misses the frightened stare or rapidly winking, shifting gaze. The goitre patient talks rapidly and underestimates the seriousness of the situation. The pulse fluctuations of goitre cases are not as rapid nor as great as in neurasthenics. Thrills and bruits are present over the superior thyroid vessels in nearly eighty per cent. of cases. In many cases, moreover, we hear over the pulmonic area a systolic murmur, short and distinctly hard in quality, though often faint.

Lung Stones.—L. G. Heyn (*Lancet-Clinic*, October 7, 1916) asserts that the presence of one or more lung stones leads to a definite, distinctive clinical picture resembling, on the one hand, that of enlarged bronchial glands and, on the other, that of pulmonary hemorrhage due to erosion of lung parenchyma or a bronchus. His patient, a man of thirty-four years, suffered from harassing cough, increasing in recumbency, except when lying on the left side. There was inspiratory dyspnea, with some stridor, localized pain beneath the fourth left costosternal junction, and a sensation as if "something wanted to come up." There was no fever or loss of weight. The chest showed some hyperresonance, with harsh, puerile breath sounds throughout and a few scattered dry rales. X ray and repeated examinations for tubercle bacilli were negative. While in Colorado, during a fit of coughing, the patient brought up an irregularly shaped stone measuring 1.1 by 0.9 by 0.6 cm. This was followed by prompt return to complete health. Heyn cites seventeen cases of pneumoliths from the literature; in eight of these the lung stones were discovered only at autopsy.

Significance of the Ammonia Coefficient in Obstetrical Work.—James R. Garber (*Southern Medical Journal*, October, 1916) comes to the following conclusions: 1, The imperfect reaction of the maternal organism to the growing ovum is the usual predisposing factor in all cases of vomiting in pregnancy. 2, Reflex or neurotic influences are usually the exciting factor. 3, True toxemic vomiting is accompanied by serious changes in metabolism. 4, A high ammonia coefficient is not specific. It may indicate toxic vomiting or starvation following neurotic vomiting, or an acidosis due to various causes. 5, The ammonia coefficient is merely a danger signal and is always to be considered in connection with the clinical symptoms. This is especially applicable to a high coefficient. 6, A low ammonia coefficient indicates neurotic vomiting and is readily treated by suggestion. 7, When there are slight variations of and a persistently high ammonia coefficient, a positive diagnosis of toxic vomiting is indicated. When the ammonia coefficient curve has wide variations, sometimes falling to a low percentage, and is associated with pronounced nervous influences, there is little doubt that one is dealing with neurotic vomiting. 8, Chloroform produces characteristic lesions of the liver, and therefore should not be used as the anesthetic. The best anesthetic is nitrous oxide-oxygen. 9, The determination of the noncoagulable nitrogen coefficient assists in differentiating renal from hepatic conditions. Its chief use is to indicate the extent of the renal involvement.

Pyocyaneus Disease.—P. L. Bosellin (*Giornale italiano delle malattie veneree e della pelle,* September 20, 1916) reports a case of pyocyaneus infection with destruction of tissue on the anterior aspect of the left wrist in a woman of forty-six years. This disease in the newborn and adult is a definite morbid entity with multiform clinical aspects, and the diagnosis should be aided or cleared up by laboratory examination when the clinical evidence is insufficient.

Fatal Hemorrhage in Bone Tuberculosis.—Robert C. Patterson (*American Journal of Orthopedic Surgery,* October, 1916) reports a case of tuberculous involvement of the lungs and many bones and joints and glands in various parts of the body. Uncontrollable hemorrhage developed from a draining sinus in the sternum. After a post mortem study it was thought that the tuberculous process had extended into the internal mammary vessels.

Syphilitic Superinfection and Reinfection.—Ettore Mariotti (*Giornale italiano delle malattie veneree e della pelle,* September 20, 1916), in reporting two cases, gives an exhaustive review of the literature and concludes that it is not impossible for a syphilitic patient to sustain a new infection during any stage of the disease. During or after energetic antisyphilitic treatment the patient may acquire an exogenous reinfection. Energetic mercurial treatments, especially injections of calomel, greatly attenuate the infection and impede the corrosive action of the specific toxin.

Estimation of Myocardial Efficiency. — J. Strickland Goodall (*Brit. Med. Jour.,* October 14, 1916) asserts that the only satisfactory method for such an estimation is one which actually tests the cardiac and circulatory response to known amounts of work. The simplest test consists in weighing the patient in pounds and giving him various measured amounts of work in specified periods of time by making him run up steps of measured height. Before the test his pulse rate, respiration rate, and systolic brachial blood pressure should be read, and these observations should be taken at once and for several minutes after the end of the exercise. If the heart is in good condition all three of these factors rise with exercise and fall to normal within three minutes thereafter. A fair reaction shows the same phenomena with a less rapid return to the normal. Poor reactions are indicated by rises in pulse and respiratory rates without a rise in the systolic blood pressure. Finally, very bad reactions show an actual fall in the systolic blood pressure. For less vigorous persons the tests may be applied with exercisers and graded weights to lift, or with an inclined plane of a grade of one to eight. The total reserve capacity of the heart may also be determined by these tests by the repetition of the work in increasing amounts until the systolic blood pressure ceases to rise. The total power having thus been determined, if it is below normal the tests may be converted into therapeutic exercises by reducing them to amounts of work less than the limit and having them carried out daily for periods of one week, with a total work test at the end of each week and an appropriate increase in exercise prescribed on the basis of results.

The Influence of War on Diabetes mellitus.—C. con Noorden (*Medizinische Klinik,* September 17, 1916) in a study of over 100 cases reveals the fact that only one occurred in a member of the reserves, the rest being found among those actively engaged at the front. It was determined that the elements of nervous strain and bodily fear played minor roles in provoking the condition. The chief causes seemed to be increased physical efforts combined with poor living conditions and an improper diet. About sixty-five per cent. of the cases occurred in men who had not previously shown signs of diabetes, the remainder either having had the disease in mild form or having shown some tendency to it. The latter group provided the majority of the severe cases. In most instances from both groups, however, proper medical care and diet removed the glycosuria and a considerable proportion of the men were sufficiently restored to be available for military service of a less active form than that at the front. The most important index of the condition of the men was found to be the state of the blood sugar—not the degree of glycosuria. If the blood sugar remained high after treatment the prognosis was not so favorable as if it fell fairly promptly to normal. Even after the greatest improvement possible the severer cases were deemed no longer capable of military service of any type.

Fractional Gastric Analysis.—Ernest C. Fishbaugh (*Journal A. M. A.,* October 28, 1916) reports the futility of the ordinary single withdrawal of a test meal as an index of the gastric function, and emphasizes this by a record of the results obtained by the fractional method and the Rehfuss tube. Using a breakfast of forty grams of water crackers and 300 mils of water and withdrawing samples of the gastric contents at twenty minute intervals, it was possible to classify the results in three divisions. The first included those cases in which the gastric secretion of acid and ferments fell toward the end of gastric digestion. The acidity varied from very low to decidedly high and the pepsin followed the curve of the acid. In this group there were all grades from hypacidity to hyperacidity and hyposecretion to hypersecretion. The maximum acidity was reached in times varying from one to two and a half hours after the meal, with an average of one and a half hour. The second group showed a continual rise in gastric secretions to the end of gastric digestion. In this group the pepsin secretion also usually followed the curve of acid secretion. Here, also, the total range included hypacidity and secretion to hyperacidity and secretion. In the third group the gastric secretions were found to be either absent or greatly delayed and this group contained three classes of cases: 1. Absence of both acid and enzymes; 2. Absence of acid alone; 3. Presence of both, but their late appearance. The first of these forms was very rare. All of the forms of curves of gastric activity were encountered repeatedly in apparently normal persons and it was found that each subject had his own particular type of curve which remained constant upon repeated examination. It was not possible to state that any one type was normal or abnormal from the data so far obtained.

Proceedings of National and Local Societies

AMERICAN LARYNGOLOGICAL ASSOCIATION.

Thirty-eighth Annual Congress Held at Washington, D. C., May 9, 10, and 11, 1916.

The President, Dr. G. HUDSON-MAKUEN, in the Chair.

(*Continued from page 925.*)

Angioma of the Larynx (*Continued*).—Owing to the yielding character of the growth, its bluish tinge, and the history of previous bleeding, the diagnosis was made of angioma of the larynx. Removal of a portion for diagnosis was deemed too dangerous, and external operation was advised. This was subsequently performed by Dr. C. A. Elsberg. The growth was removed, the mucous membrane sutured, and the pathologist reported a hemangioma. The patient made an uneventful recovery. Doctor Mayer concluded that angioma of the larynx was a rare disease, occurring mostly in adults, the proportion of males to females being about four to one. It might be mistaken for cancer. Endolaryngeal removal, even of a portion of the growth, for diagnosis was fraught with danger, while laryngofissure was entirely safe and feasible.

Dr. HENRY L. SWAIN, of New Haven, remarked that if Doctor Mayer wanted another case simply to bear out what he said about the danger in these cases, he could mention one in which he attempted to remove a growth of this kind. They got hemorrhage all right. If anything further was needed to substantiate the diagnosis, the microscope did. He had a slide at home showing it to be true angioma of that type. He was interested to hear what Doctor Lynch thought he could do with such a case by suspension.

Dr. ROBERT CLYDE LYNCH, of New Orleans, had never had an opportunity of seeing one of these cases, and had, therefore, had no personal experience with them. He thought, however, that if it was possible to get underneath the place, and if the surface was not too broad and the position properly localized, it might be possible to do it under suspension. However, that could be decided at the time the case presented itself. After seeing the illustration of the size and site of this angioma, he would not attempt its removal under suspension.

Further Progress in the Use of Radium in the Field of Laryngology.—Dr. D. BRYSON DELAVAN, of New York, said that decided advances had been made during the past year in their knowledge of the application of radium in diseases of the upper air passages, while the number of the conditions in which it was found effective was being steadily increased. Several institutions, notably the General Memorial Hospital of New York, had been fortunate in acquiring amounts of radium large enough to meet all probable demands; while those administering it were gaining experience in its use and learning how it might best be used and controlled.

As to the uses of radium, closely allied to their department might be mentioned the success of radium in "vernal catarrh," or that form of conjunctivitis which occurred during the spring, and often, when established, lasted throughout the year. Abbe had observed ten cases, recurrent for many years, and asserted that improvement always began soon after the first treatment. Even patients who had been previously treated by the removal of hypertrophied masses, cauterization, and caustics, received uniform benefit from radium and were ultimately cured. A second interesting condition in which radium had no rival was in the reduction of lymphoid tumor cases, as found in tumors of the tongue, called hemolymphangioma. The treatment by radium of papillomata of the larynx, as with warty growths in general in other parts of the body, was being attended with ever increasing success. Leucoplakia of the tongue, Abbe believed, was as capable of cure by radium within the mouth as was the skin hyperkeratosis. In the mouth, however, the duration and the method of application required more judgment and skill to attain good results. The treatment was associated with transient painful irritation, but this seemed essential to success. Chronic abrasions and fissures of the lip were curable by radium. In the treatment of nevus, excellent results were being obtained. New growths of nonmalignant type were receiving an increasing amount of attention, with excellent results. Thus, Abbe had shown a case of myeloid tumor of the lower jaw completely cured. Tumors of the larynx of various kinds had been caused to disapear, with complete return of the singing voice. In the field of nasopharyngeal fibroma the use of radium was most encouraging, particularly so in view of its success in the treatment of fibromata of the uterus.

Two cases observed by the speaker, of sphenoid carcinoma, were worthy of notice. Both originated in the left side of the throat, close to the wall of the larynx, probably exolaryngeal. Both were seen late, long after operation would have been possible. Both patients were men in the early fifties, hitherto in perfect health, active, vigorous, and of good antecedents. When first seen, the disease in both had invaded the interior of the larynx, the left lateral wall of the pharynx, the pyriform sinus, the tonsil, and the base of the tongue. In both, ulcerations were present and there was marked aphonia and dysphagia. Both were treated at the same institution, exposed to large doses of radium, and in both the results were materially the same. The first effect locally was an almost immediate control of the secretions of the throat. From having been abundant and fetid, they promptly ceased. Following this, the areas of ulceration rapidly diminished in extent, and in the less severe of the two cases disappeared, while in the other case they seemed to do so. The swellings, which had appeared over extensive areas of the affected parts, decreased greatly and the infiltrated tissues were reduced in size, became soft to the touch, and more natural in appearance. Meanwhile the voice became clearer, and deglutition improved so that both patients were

able to swallow without pain, and to increase largely the variety of their food. The general improvement was remarkable. Digestion became normal, and sleep more prolonged and restful. Strength increased steadily, and there was an almost normal condition of good spirits. One patient, a physician, was able to resume office practice and operative work for a period of over two months. Both had agreed that if the further progress of the disease should be entirely unfavorable, the benefit gained in the relief of suffering and the added comfort afforded would well have repaid them for any inconvenience which the radium had caused, whether from burns of the skin or from any other result.

Already results worthy of profound consideration had been obtained. Far from being discouraged, there was every reason why they should make persistent and continued effort finally to solve the existing problems and give to the world a successful cure.

Dr. Cornelius G. Coakley, of New York, believed that the great trouble with the use of radium was that they could find little or nothing to be used as a guide in the doses of this material. Doctor Delavan mentioned in his paper "the application of a tube of strong radium for fifteen minutes." Now, that did not mean anything to those working with it. He would like to know the actual amount of it to be a guide to other men. Another great difficulty with the use of radium was the enormous expense of the material. At the present time they were having placed at their disposal by the Crocker Institute about one hundred grams of radium, the cost of which was somewhere over $10,000. They used it in various pathological conditions. That was a prohibitive cost for most men in the practice of medicine.

Their greatest difficulty was that it burned, and it burned very severely. They had not yet been able properly to screen this material when placed in the mouth, or in the nose, or nasopharynx, or on the exterior of the body so as to have it reach the object of the pathological process without getting more or less burning. If they used too little, they did not get enough action; if too much, they got terrific burns which occurred not at the time, but even months later, as happened in one case treated by radium at Johns Hopkins. The patient had an application of radium a year ago last March, and the burn did not manifest itself until August of last year. In one of his own cases in which they applied it, a portion of the nose had been burned off as a result of the action, the burn coming on six months after the application. The radium destroyed the growth in the nose, but also almost all of the nose as well. It caused external thrombus and finally destruction. Those were some of the things with which they had to contend. They knew nothing themselves, and there was very little in the literature to guide them in escaping those factors.

There was one other point in relation to malignancy. If they used it they would unquestionably stimulate the action of the malignant process in the same way as they would if they curetted or cauterized it. If they were going to use radium, they had to get it right into the mass and have an amount which the ordinary practitioner could not afford to invest in, if they desired to do more than merely stimulate the growth.

Dr. Jacob H. Hartman, of Baltimore, desired to report a most unusual experience. In August, 1913, there was a patient, a gentleman, sent by his family physician with an endolaryngeal growth, of a red, angry color, filling up a large part of the larynx and interfering with the respiration. The speaker gave him an unfavorable prognosis and advised him to have another opinion. He was taken for consultation to Doctor Winslow, who agreed that the growth was undoubtedly malignant in character and inoperable. On September 4th, two small portions were removed very carefully for pathological examination. The microscopic examination was made and the specimen reported malignant. On September 14th, a tracheotomy was performed. On September 21st, radium was applied externally for three hours. On September 24th, radium was again applied for nine hours, and was followed by most extensive burns all over the neck, and the patient suffered intensely. On October 6th, there was almost complete obliteration of the growth, and on October 23d, the patient was again examined and there was no vestige of the growth at all, only a slight thickening of the mucous membrane over the arytenoid space. The larynx was absolutely normal. April 12, 1916, the larynx was thoroughly clean, and there was no evidence of growth noted at all. The patient had gained thirty to forty pounds and was remarkably well and absolutely free from any trouble of this kind.

Dr. Harmon Smith, of New York, told how, about three years ago, a young boy, twelve years of age, who had a large growth, was sent to the General Memorial Hospital in New York, where they now had some of the strongest radium in this country. At that time the application of radium only increased the growth, but they had not the strength of radium that they had at present. The boy was sent to him and had the growth removed on two different occasions with considerable hemorrhage, nearly fatal, each time. Injections of ammonium chloride and trichloracetic acid failed to hold it in check. The condition progressed gradually, the boy became anemic, and the growth extended out into the jaw and filled up the cheek. Some weeks ago he was sent back to the General Memorial Hospital, where they applied radium once for a period of three hours. Following that he had a hemorrhage, and a few days after the hemorrhage an edema of the larynx set up which necessitated tracheotomy, and the boy died.

He recalled a case of similar character where removal had not completed the disappearance of the growth and it had recurred, so this young boy, about nineteen years of age, was sent to have his application of radium at the same time. He had an application of strong radium which set up such inflammation in the cheek and the tissues adjacent to the growth, that for at least a week the boy was unable to swallow at all. They had to feed him by rectum and it became a very serious proposition; so that, in his opinion, they should know more about the action of radium before applying it indiscriminately. Yet this radium was in the hands of an expert, and applied at a hospital where radium

was being used experimentally as well as practically. He also had three cases of cancer of the larynx which required tracheotomy, and a tube of radium was inserted to be left as long as was seen fit. Those cases went on without apparent benefit to death.

Dr. John R. Winslow, of Baltimore, told how it was his privilege to see the case mentioned by Doctor Hartman from the beginning until the end. The last time he examined it there was no evidence of growth, nor any indication of the site of attachment of the growth. One who had not seen the case previously would have been unable to determine whether there had ever been any pathological condition in the larynx. Of course, the case was an absolute cure of a condition which, as far as his experience and judgment went, would have been an absolutely incurable and inoperable one.

An interesting thought occurred to him as to what happened to these growths. He took particular pains to inquire of this patient whether he had had any increased expectoration or secretion in any way pointing to a breaking down by ulceration, or similar process, and he admitted no such condition. Apparently the growth simply disappeared.

Dr. Cornelius G. Coakley, of New York, wished to ask, with reference to Doctor Hartman's case, whether the growth of the larynx was ulcerated, and what was the strength of radium used.

Dr. John R. Winslow, of Baltimore, said they were greatly handicapped, for while they had practically one of the largest collections of radium in the country, it belonged to an incorporated, private institution which was conducted largely on a commercial basis. The cost of an application of radium was somewhere in the neighborhood of $100, if not more. That, in itself, was almost prohibitive in many cases, so that it could only be used exceptionally. There was no one who had obtained a loan of radium, and so far as he knew there was no Government institution for this purpose. It seemed to him it was a field in which the Government should take a hand and incorporate a national radium institute for the benefit of the public.

Just before he came away he saw an epithelioma of the nose, completely filling the nose and invading the ethmoid, as well as causing protuberance of the eyeball, in which he expected, if possible, to have the radium applied. It was absolutely inoperable. The patient was seventy-nine years of age, and the tumor myxomatous in appearance, bleeding on touch. While there had been no opportunity of removing a specimen for examination, he had no doubt that it was an epitheliomatous.

Answering Doctor Coakley's question as to whether the growth in the larynx was ulcerated, and the strength of the radium used in Doctor Hartman's case, there was no ulceration and no involvement of the glands. He did not know in what strength the radium was used, but he knew it was very strong.

Dr. Robert Clyde Lynch, of New Orleans, had had two or three experiences with the use of radium. The first case was that of a patient with sarcoma of the nose, treated two years ago. He did the first stage of the Caldwell-Luc operation and put in the radium, unscreened—simply the little capsule with the glass container which held the radium into the nose and antral cavity. This was a fifty-five mm. tube. The diagnosis of sarcoma had been made by microscopic examination, and the nose had been blocked up completely. In the course of four weeks there was free nasal respiration, and an examination with the Holmes laryngoscope did not reveal any evidence of the growth.

The second case was one of an intrinsic laryngeal growth in which an extension occurred, necessitating something else being done. Seventy-five mgm. of radium were applied externally, fifty on the diseased side and twenty-five on the opposite side, the radium being screened with brass, then four rows of sheet lead, then the same thickness of aluminum, then gauze, and finally a rubber cot. This roll was applied to the outside of the larynx and left for twelve hours. Two days following the application there appeared the most beautiful sunburn, the larynx was extremely red, and the patient complained a little. The growth became pale, white, and dry; it gave the appearance through the mirror of being dry. After a rest of five days and a reapplication for eight hours, a recurrence of this burn appeared, though not so much. Then there was a rest of one week and a reapplication for twelve hours. After this there was an apparent retraction of the growth. The surface remained dry and gave the impression as if the deeper invasion of the growth toward the cartilage was becoming less. He had devised an intubation tube for the endolaryngeal application of radium. In reporting an application of radium, he thought they ought to lay special stress upon the size of the dose and the length of application.

Dr. Henry L. Swain, of New Haven, in a case exactly similar to the one cited by Doctor Winslow, in which he was expecting to use radium, had used the capsule as mentioned by Doctor Lynch. In this case they merely put the capsule into the substance of the growth, which bled profusely for a little while. The capsule was allowed to remain in over night and the patient sent home in the morning. An external burn resulted from the application and recession of the growth. Doctor Winslow was interested to know what became of these growths. This was one of those pale, flat growths, and it became rosy hued, and all of this rose hued area eventually disappeared by mild ulceration. The whole growth was not exposed to this application of radium, so a second application was given about six weeks after the original application, at this time the radium remaining for nearly five hours. It was now only three months since the second application, and the growth had practically disappeared; at least we cannot find any trace with careful search. He thought it was extremely valuable to recite their experiences in this way and discuss them from so many angles.

Dr. Cornelius G. Coakley, of New York, said that seventy-five mgm. of radium, when put into the growth and left there, would cause an enormous amount of destruction. Seventy-five mgm. applied on the outside of the neck for involvement of the larynx, or tonsil, or pharyngeal mucous

membrane, would not do very much. They must have an enormous amount, four hundred or one thousand mgm., if they wished to get results from external applications through healthy tissue to malignant tissue. This must be left in about three or four hours. He thought the best results were obtained by strong doses applied for a short time, and then reapplied at short intervals of about two or three days.

Dr. D. Bryson Delavan, of New York, said that there were some things which belonged to the laboratory. Radium did, because it required large amounts to produce effects. The general practitioner had no more to do with radium than the driver of a hackney coach with the New York Central Railroad. It was something the general practitioner could not, in the nature of things, know about. It was something that even Doctor Abbe, who for many years had spent such a large amount of study upon the subject, did not know enough about to specify. It was something which was so new and the discussion of which was so fresh that there was actually no literature to guide them. There was nothing which they could use as a guide, but the work being done in a few places by a few men.

The largest amount of radium in this country was at the laboratory with which he had the honor of being slightly connected. There were two other institutions doing the best work they knew how to do and trying hard to learn just how to do the work—the one to which Doctor Coakley referred. and the other was one under Doctor Bissell at Johns Hopkins. Their institution would soon have two grams of radium, and he did not know any place in Europe that had as good a supply. Radium had not yet proved a cure for cancer, but it had a possibility, and that possibility was worthy of following up. Radium would burn. Well, it hurt to be operated upon in any way. It was not pleasant to take ether and be laid up for a month or two, or five months, after painful surgery, but it was a very beautiful thing to be well and among friends. And so it was with the use of radium. Suppose it did burn? In those two cases cited both patients suffered severe burns, but they rejoiced at it, even though they did not result in cures, but only in temporary benefit.

If there was nothing in radium, why, they had tried and done their best; if there was, there was a great prize in store.

Epidemic of a Severe Form of Acute Infection of the Throat with Abscess Formation.—Dr. Clement F. Theisen, of Albany, observed that this epidemic occurred in Albany during December, 1915, and January and February, 1916. Cases occurred in all parts of Albany, 384 coming under the speaker's personal observation. Fifty-eight of the patients had abscesses in different parts of the fauces. Forty-four of this number were more or less typical cases of peritonsillar abscess. Of the remaining fourteen cases, in eight abscesses developed in the lateral columns of the pharynx. There were two cases of infection of the epiglottis with great edema and some pus, two cases of abscess of the lingual tonsil, and two of retropharyngeal abscess. Joint complications, acute arthritis, and polyarthritis occurred in twelve cases, acute endocarditis in one, and in twenty-four examination of the urine showed the presence of albumin and casts. In sixty-eight cases acute otitis media developed, requiring incision of the tympanic membrane, with one mastoid complication in a young child whose membrana tympani ruptured ten days before the speaker was called. Cultures taken during the epidemic showed streptococcus infections in the majority of the cases. A few were pneumococcus infections. The milk supply was probably not a factor. There were no deaths among the speaker's cases, although some patients were seriously ill, particularly those with joint and kidney complications. The onset of the attack in most cases was extremely severe, with chills, great prostration, swelling of the glands of the neck, and high temperatures, particularly in children.

(To be continued.)

Letters to the Editors

RHUS POISONING.

Syracuse, N. Y., *November 6, 1916.*

To the Editors:

Nearly every year I am a victim to ivy poisoning, and beside my personal experience, I see many cases in practice. A localized, intense itching and burning are the first symptoms, followed in a few days with papules which fill with serum. With no treatment or the ordinary treatment of washes and ointments, it subsides in ten days or two weeks, and there is a desquamation of the parts involved.

Maisch, in 1865, made experiments and attributed the poison to a volatile acid which he named toxicondendric acid, but which Pfaff (*Jour. Experimental Med.*, II, 1897, p. 181) identified with acetic acid. Pfaff found the poisonous principle to be an oil which caused the eruption only in places where it had been applied, if care was taken not to distribute it to other parts of the body.

Many years ago, in desperation to relieve the itching, I would saturate a bit of cotton with chloroform and rub the part—generally fingers—and I soon found that I could abort the attack. The itching would gradually subside and the papules would not form. After reading Pfaff's contribution, it was plain to see that in using the chloroform I had cleansed my hands from the poison. Since then I have substituted benzol for chloroform, as it is a better solvent for oily and resinous substances, and gasoline is about as efficient.

One has only to scrub thoroughly and clean the part as soon as the first symptoms appear to be relieved.

John B. Todd, M. D.

DOCTOR DAVIN AND THE ANDERSON TRIAL.

New York, *November 2, 1916.*

To the Editors:

During the progress of the Anderson trial in Brooklyn I was reported in the newspapers as having said that the case was not one of anterior poliomyelitis.

I endeavored in vain to obtain a retraction of this statement, both from the reporters and the editors responsible for it. The enclosed article, which gives my position in the proceedings, is only likely to have a limited circulation among those who read these newspaper stories. Its republication in your journal would remedy this drawback as far as it relates to my professional brethren, whose opinion I value and whom I would like to reach with my side of the story.[1] If this is inexpedient I would like to have published the statement that at no time did I give to any one, not even to counsel, my opinion of the case until it was given to the Court while I was on the stand.

John P. Davin, M. D.

[1]The article referred to by Dr. Davin, which we regret being unable to republish, appears in the *Medical Economist* for October, page 208, under the title of Psychology of the Public.

Book Reviews

[We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.]

Changes in the Food Supply and Their Relation to Nutrition. By Lafayette B. Mendell, Professor of Physiological Chemistry in the Sheffiield Scientific School of Yale University. New Haven: Yale University Press, 1916. Pp. 61.

This little book is a collection of the author's remarks at the second Pan American Scientific Congress at Washington in 1915. It begins with a discussion of the problem of food production as it will soon face the rapidly growing populations. Food preservation and food conservation are taken up next, then transportation facilities, customs in diet, and changing industrial and social conditions. One way in which food products will meet increase of population is by addition to their number; within the last few months attention has been directed to the possibility of growing in the United States at least two plant products which may serve as human foods, i. e., proso millet and grain sorghum or kaoliang, both of which have been known in other parts of the world as constituents of the diet of mankind. It is pointed out (page 22) that protein has lost the special significance it possessed in Liebig's day as the sole source of energy. The too great consumption of meat in America is discussed, pride in the ability to buy it being one reason for its excessive use. Advertising is blamed for the excessive gum chewing in the United States, also, on the other hand, for the healthful substitution of cereals for meat and eggs at breakfast. It is said—not in this book, however—that gum chewing is common among the Allies in the European war. There are many other interesting items, e. g., that although the bakers in the United States are capitalized at $270,000,000, still seventy per cent. of our bread is home made. We commend this little volume as a useful and entertaining one.

Diseases of the Digestive Tract and Their Treatment. By A. Everett Austin, A. M., M. D., Former Professor of Physiological Chemistry at Tufts College, University of Virginia and University of Texas; Present Assistant Professor of Clinical Medicine, in Charge of Dietetics and Gastrointestinal Diseases, Tufts College, etc. With Eighty-five Illustrations, Including Ten Color Plates. St. Louis: C. V. Mosby Company, 1916. Pp. 552.

This book is conveniently divided into three parts; the first deals with general characteristics, the second with special gastric diseases, and the third with special intestinal diseases. The first part is by far the largest, and is, we think, the most valuable part of the work. There are chapters on the surface anatomy of the stomach and intestines, the physiology of digestion, examination of the patient, physical methods of examination of the digestive tract, acquisition and examination of gastric contents, examination of feces, dietetics in digestive disorders, and treatment of digestive disorders. Most of these chapters are well worth reading and contain in readily available form much information which the usual textbooks are careful to omit. The chapters on examination of the patient, dietetics, and treatment are particularly good. The chapter on digestion could be enlarged with advantage, for it contains less than what may be found in any book on physiology. The second and third parts of the book are concerned with the chief gastric and intestinal diseases, and may suffice as an introduction to the subject or as a serviceable summary. These parts are less complete than the corresponding sections in any good book on practice, and are far too brief to satisfy a specialist. The book is well printed and is adequately illustrated, but it lacks a bibliography. The author refers constantly to the various workers and writers, but forgets to say where any account of their work may be found. Incidentally, the author (in the first sentence of the preface) seems to have settled to his own satisfaction the vexed question of the authorship of the book of *Ecclesiastes;* unfortunately we have no proof that Milton lived in biblical times. Expressions like *per oram* and *per anus* should be corrected.

Differential-diagnostische Tabellen. der inneren Krankheiten. Von Dr. med. J. Cemach, Wien. 46 Tabellen mit 18 farbigen und schwarzen Abbildungen sowie 8 Fiebertypen. Zweite, vermehrte und verbesserte Auflage. München: J. F. Lehmanns, 1915.

This small book consists of a series of diagnostic tables, twenty-one in number, in which are compared the clinical and etiological features of affections of various organs of the body. Its object is not to replace the textbook of medicine, but to place before the eyes, so arranged as to permit of rapid comparison, the essential diagnostic signs of the various disorders, thereby facilitating quick differentiation and preventing omission, in the comparisons made, of any important clinical feature. Only the typical forms of the various diseases are taken up. In this new, second edition, a number of additional or subsidiary tables have been inserted. A few illustrations and temperature charts are also included where concise description is impossible.

S. Weir Mitchell, M.D., LL.D., F.R.S., 1829-1914. Memorial Addresses and Resolutions. Philadelphia, 1914. Pp. 155.

This book contains a series of personal tributes rendered the late Doctor Mitchell at a special meeting of the College of Physicians of Philadelphia; various minutes of appreciation passed by the Board of Trustees of the University of Pennsylvania, the Council of the University Medical School, the Directors of the Library Company of Philadelphia, and the Board of Trustees of the Jefferson Medical College, and the proceedings of a joint meeting held in memory of Doctor Mitchell by various learned societies of Philadelphia. At the last named meeting addresses were made by Mr. Talcott Williams, of Columbia University; Dr. William H. Welch, of Johns Hopkins University, and Mr. Owen Wister. In these various eulogies the essential characteristics and manifold activities of this untiring worker in medicine and literature are fittingly set forth. His medical labors are described by Doctor Welch, and his achievements and place in American literature pointed out by Owen Wister, his kinsman, who classes *Hugh Wynne* and *Westways* with the works of Trollope and Fielding, because they are friendly to mankind, not sensationally misanthropic. In spite of Mitchell's extensive knowledge of pain, evil, and sorrow, gained from "four years' observation of mutilated soldiers and fifty years' study of hysteria, neurosis, insanity, and drug mania, . . . the tone of Doctor Mitchell's books is a lesson and a tonic for an age that is sick and weak with literary perverts." This Owen Wister deems literature's true debt to him.

A Practical Treatise on Disorders of the Sexual Function in the Male and Female. By Max Hühner, M. D., Chief of Clinic, Genitourinary Department, Mount Sinai Hospital Dispensary, New York City; Formerly Attending Genitourinary Surgeon, Bellevue Hospital, Out Patient Department, and Assistant Gynecologist, Mount Sinai Hospital Dispensary, New York City, etc. Philadelphia: F. A. Davis Company, 1916. Pp. xv-318. (Price, $3.)

The greater part of the present volume has already appeared in print in various medical journals and elsewhere. The publishing of these papers in a single volume will insure for them a wider circulation and a longer life. Those who are at all acquainted with the literature of the subject will find nothing new or unusual in the present work; but it is quite possible that many practitioners will appreciate a book of this kind, especially those parts which deal with the management of such of the sexual neuroses as are amenable to treatment. The author handles his subject in a plain, straightforward way, and since he is, as a rule, eminently "orthodox," the present contribution will offend very few, and may possibly be read by some who would be repelled by more authoritative and scientific books. We would like to know the author's authority for the statement (page 185) that it is the presence of vaginismus which causes *demi-vierges* to object to sexual intercourse; if such is really the case, vaginismus must be much more common than we had supposed. The "bibliography" at the end of the volume is not really a bibliography of the subject; it is rather a reference to the sources from which the author derived some of his information. Still, it makes interesting reading and supplies food for thought; the omissions, in some cases, are more eloquent than the names printed.

Interclinical Notes

The *Survey* for October 28th discusses editorially infant mortality, housing reform, and working hours for women. "So long as mothers work in factories," observes Doctor Robin, of Wilmington, Del., a valued member of the staff of the NEW YORK MEDICAL JOURNAL, "so long will babes go to their graves."

* * *

What with war, patriotism, religion, rebellion, the prospects of an enlarged periodical, etc., divvle a word is there about medicine in the *Outlook* for November 8th. It is an interesting issue, nevertheless; it pays particular attention to the status of the troops, regulars and militia, now scattered along the Mexican border. The guardsmen come in for some severe criticism for their lack of military appearance, etc. There is a sympathetic account of the career of the late William Merritt Chase.

* * *

Fiction chosen with unusual care seems to be the principal feature of the November *Century*. The short stories are The Persistent Little Fool, by Fanny Kemble Johnson; Olivia Mist, by Vincent O'Sullivan; The Sea Green Incorruptible, by E. F. Benson; and A Transit of Venus, by Marjory Morten. The superb serial, by William Dean Howells, The Leatherwood God, comes to a close, and Aurora the Magnificent, by Gertrude Hall, takes its place. The illustrations and other pictures are, as usual very fine.

* * *

"Chain your doctor" is the advice given by *Pulp and Paper Magazine* for August 15, 1916; very good advice, too, if the doctor is guilty of such outrageous conduct as charged further on. We suppose the doctor must have kicked the casting out of place or it would not have dropped him so suddenly. Here is the item, however, and our readers may judge for themselves: "In one of the Ontario Mills recently, one of their employees lost a leg, owing to a calender doctor falling. The injured man was performing his duties at the calender stack and without provocation one of the castings supporting a doctor broke, permitting the doctor to fall, striking the workman on the leg, crushing it so that amputation was necessary. While this sort of accident is very rare it shows that great care must be exercised in inspecting these castings. The company immediately chained all doctors to the frame of the stack. This gives absolute protection against a similar accident. We are calling attention to this in hopes that it may be a warning to other mills." The least the doctor can do is to replace the lost leg. The prompt action of the company is worthy of all praise.

Meetings of Local Medical Societies

MONDAY, *November 13th.*—New York Ophthalmological Society; Society of Medical Jurisprudence, New New York; Roswell Park Medical Club, Buffalo; Williamsburg Medical Society, Brooklyn; New Rochelle, N. Y., Medical Society; Yorkville Medical Society (annual).

TUESDAY, *November 14th.*—New York Academy of Medicine (Section in Neurology and Psychiatry); Medical Society of the County of Schenectady; Medical Society of the County of Rensselaer; Buffalo Academy of Medicine; Newburgh Bay Medical Society; New York Obstetrical Society.

WEDNESDAY, *November 15th.*—New York Academy of Medicine (Section in Genitourinary Diseases); Alumni Association of City Hospital, New York; Schenectady Academy of Medicine; Women's Medical Association of New York City (New York Academy of Medicine); Medicolegal Society, New York; Buffalo Medical Club; Northwestern Medical and Surgical Society of New York; Bronx County Medical Society (annual); Dunkirk and Fredonia Medical Society; Buffalo Academy of Medicine.

THURSDAY, *November 16th.*—New York Academy of Medicine (stated meeting); Auburn City Medical Society; Geneva Medical Society; German Medical Society, Brooklyn; Æsculapian Club, of Buffalo; New York Celtic Medical Society.

FRIDAY, *November 17th.*—New York Academy of Medicine (Section in Orthopedic Surgery); Mount Vernon Medical Society; Alumni Association of Roosevelt Hospital; New York Microscopical Society; Clinical Society of the New York Post-Graduate Medical School and Hospital.

Official News

United States Public Health Service:

Official list of changes in the stations and duties of commissioned and other officers of the United States Public Health Service for the seven days ending November 1, 1916:

ARMSTRONG, CHARLES, Assistant Surgeon. Continued on duty at Ellis Island, N. Y.

CORPUT, G. M., Surgeon. Granted four days' leave of absence on account of sickness from October 19, 1916.

COX, ORA H., Assistant Surgeon. Relieved from duty at Ellis Island, N. Y., and will proceed to Saulte Saint Marie, Mich., for duty; granted three days' leave of absence en route.

DYER, R. E., Assistant Surgeon. Continued on duty in plague eradicative measures at New Orleans, La.

EDMUNDS, MEADE C., Assistant Surgeon. Continued on duty at the Marine Hospital, St. Louis, Mo.

ESKEY, C. R., Assistant Surgeon. Relieved from duty at the Marine Hospital, Chicago, Ill.; will proceed to Ellis Island, N. Y., for duty.

FROST, W. H., Passed Assistant. Will deliver an address on poliomyelitis at the annual meeting of the Southern Medical Association at Atlanta, Ga., November 13-16, 1916.

FULLER, J .K., Assistant Surgeon. Continued on duty at the plague laboratory, San Francisco, Cal.

GORMAN, P. J., Assistant Surgeon. Relieved from duty at the Marine Hospital, Chicago, Ill., and ordered to report to the commanding officer, Coast Guard cutter *Tampa.*

GRIMM, R. M., Passed Assistant Surgeon. Bureau letter dated September 28, 1916, amended to read "nine days' leave of absence from October 16, 1916."

HARRISON, WALTER T., Assistant Surgeon. Ordered to report for duty at San Francisco Quarantine Station, Angel Island, Cal.

HURLEY, J. R., Passed Assistant Surgeon. Assigned to duty in the Bureau of Medicine and Surgery, Washington, D. C., under Assistant Surgeon General W. C. Rucker.

IVEY, R. R., Assistant Surgeon. Detached from the New York Division of the Coast Guard; ordered to report at Barge Office, New York, N. Y., for duty in connection with the physical examination of applicants for enlistment.

LEAKE, J. P., Passed Assistant Surgeon. Ordered to proceed to Middlesex County, Va., to investigate the occurrence of cases of poliomyelitis.

LUMSDEN, L. L., Surgeon. Ordered to proceed to Carrollton, Ga., to make a preliminary sanitary survey of that town.

MCMULLEN, JOHN, Surgeon. Will deliver an address on trachoma at the annual meeting of the Southern Medical Association at Atlanta, Ga., November 13-16, 1916.

MOTTER, MURRAY G., Technical Assistant. Will deliver an address on the Public Health Service at Columbia, Pa., November 17, 1916.

MURRAY, V. B., Assistant Surgeon. Relieved from duty at the Marine Hospital, San Francisco, Cal., and ordered to report to commanding officer, Coast Guard cutter *McCulloch,* for duty.

OAKLEY, J. H., Surgeon. Granted four days' leave of absence from November 10, 1916.

PRATHER, J. J., Assistant Surgeon. Ordered to proceed to Mineola, L. I., for a survey of mental and physical conditions of groups of school children.

PERRY, J. C., Senior Surgeon. Relieved from duty as chairman of the board convened at Ellis Island, November 13, 1916.

REICHARD, J. D., Assistant Surgeon. Granted fourteen days' leave of absence from October 30, 1916.

Ridlon, J. R., Passed Assistant Surgeon. Granted one month and ten days' leave of absence from October 29, 1916.

Rucker, W. C., Assistant Surgeon General. Ordered to represent the Service at the annual convocation of the American College of Surgeons at Philadelphia, Pa., October 27, 1916.

Sprague, E. K., Surgeon. Detailed as chairman of a board convened at Ellis Island, November 13, 1916, *vice* Senior Surgeon J. C. Perry, relieved.

Wagenbach, W. F., Assistant Surgeon. Continued on duty at the Marine Hospital, St. Louis, Mo.

Warren, B. S., Surgeon. Will deliver an address on sickness insurance at the annual meeting of the Southern Medical Association, Atlanta, Ga., November 13-16, 1916.

Worley, J. F., Assistant Surgeon. Relieved from duty on Coast Guard cutter *McCulloch*, and will return to station, Marine Hospital, San Francisco.

Wynne, R. E., Assistant Surgeon. Granted three days' leave of absence en route to Stapleton, N. Y., from November 2, 1916.

Appointments.

Dr. Walter Trousdale Harrison, Dr. Charles Armstrong, Dr. Rolla Eugene Dyer, Dr. Justin Keyser Fuller, Dr. William Frederick Wagenbach, and Dr. Meade Castleton Edmunds have been appointed and commissioned as assistant surgeons from October 20, 1916.

Boards Convened.

Boards of cimmissioned medical officers convened for the physical examination for promotion of certain officers of the Coast Guard, November 6, 1916, as follows: Washington, D. C., detail for the board, Assistant Surgeon General W. G. Stimpson, chairman; Passed Assistant Surgeon W. F. Draper, recorder. Philadelphia, detail for the board, Senior Surgeon Fairfax Irwin, chairman; Assistant Surgeon Liston Paine, recorder. Baltimore, detail for the board, Surgeon C. W. Vogel, chairman; Assistant Surgeon Joseph D. Stout, recorder.

Boards of commissioned medical officers convened November 13, 1916, to conduct the examinations of applicants for appointment as assistant surgeon as follows: Ellis Island, N. Y., detail for the board, Senior Surgeon J. C. Perry, chairman; Passed Assistant Surgeon E. H. Mullan, recorder. Chicago, detail for the board, Surgeon J. O. Cobb, chairman; Assistant Surgeon H. C. Yarbrough, recorder. Cincinnati, detail for the board, Passed Assistant Surgeon W. H. Frost, chairman; Passed Assistant Surgeon Paul Preble, recorder. New Orleans, detail for the board, Passed Assistant Surgeon Friench Simpson, chairman; Assistant Surgeon S. L. Christian, recorder.

United States Navy Intelligence:

Official list of changes in the stations and duties of officers serving in the Medical Corps of the United States Navy for the two weeks ending October 28, 1916:

Allen, A. H., Passed Assistant Surgeon. Detached from the *Texas* and ordered to duty on the *Louisiana*.

Berryhill, T. A., Medical Director. Detached from duty in the Great Lakes Hospital, Ill., and ordered to the Mare Island Hospital, Cal., for duty.

Bowman, F. H., Assistant Surgeon. Ordered to the *Colorado* for duty.

Connor, W. H., Passed Assistant Surgeon. Detached from the *Kansas* and ordered to the *Olympia*.

Curtis, L. W., Medical Director. Detached from the Newport Hospital and ordered to the Great Lakes Hospital, Ill., for duty.

Gates, M. F., Medical Director. Detached from the Mare Island Hospital and ordered to the Newport Hospital.

Giltner, H. A., Acting Assistant Surgeon. Appointed an acting assistant surgeon from October 21, 1916; ordered to duty at the Navy Recruiting Station, Parkersburg, W. Va.

Hart, S. D., Passed Assistant Surgeon. Detached from duty at the Newport Training Station and ordered to the *Maumee* for duty.

Kelley, H. L., Passed Assistant Surgeon. Ordered to command the Naval Hospital, Port Royal, S. C.

Ledbetter, P. B., Passed Assistant Surgeon. Detached from duty at the Naval Hospital, Las Animas, and ordered to the Training Station, Great Lakes, Ill.

Lee, E. K., Assistant Surgeon, Medical Reserve Corps. Commissioned an assistant surgeon in the Medical Reserve Corps from September 18, 1916.

Reed, T. W., Passed Assistant Surgeon. Detached from the Naval Hospital, Norfolk, Va., and ordered to the Asiatic Station, via November transport, for duty.

Rennie, W. H., Surgeon. Resignation accepted, effective November 1, 1916.

Schmidt, L. M., Passed Assistant Surgeon. Detached from the *Louisiana* and ordered to the Norfolk Hospital for duty.

Torrence, R. A., Assistant Surgeon. Ordered to the *Texas* for duty.

Waterhouse, R. M., Assistant Surgeon. Ordered to the *Melville* for duty.

Whiteside, L. C., Passed Assistant Surgeon. Ordered to the Las Animas Hospital for duty.

Casualty.

Surgeon J. H. Holloway, retired, died at Albuquerque, New Mexico, August 2, 1916.

Births, Marriages, and Deaths

Married.

Clark-Starkey.—In Newtonville, Mass., on Wednesday, October 25th, Dr. Frank Robinson Clark, and Miss Emily Jane Starkey.

Kimberlin-Bradley.—In Alameda, Cal., on Thursday, October 19th, Dr. Lester O. Kimberlin, of San Francisco, and Miss Gladys L. Bradley.

McCartney-Mitchell.—In Littleton, Colo., on Tuesday, October 17th, Dr. Frank M. McCartney, of Denver, and Miss Elizabeth M. Mitchell, of Denver.

Myers-Goeltz.—In San Francisco, Cal., on Wednesday, October 18th, Dr. Mark C. Meyers, of San Francisco, and Miss Louise A. Goeltz, of New York.

Wood-Corey.—In Hartford, Conn., on Wednesday, October 25th, Dr. Floyd Alberti Weed and Miss Marguerite Lucille Corey.

Died.

Abbott.—In Bethel, Ohio, on Sunday, October 22d, Dr. Julius Abbott, aged seventy-one years.

Borland.—In Elizabethtown, Pa., on Friday, October 20th, Dr. John Borland, aged eighty-one years.

Connell.—In Fond du Lac, Wis., on Saturday, October 21st, Dr. James P. Connell, aged fifty-five years.

Coyle.—In Nashville, Tenn., on Saturday, October 21st, Dr. James M. Coyle, aged sixty-seven years.

Drake.—In Brooklyn, N. Y., on Sunday, October 29th, Dr. Emory G. Drake, aged sixty-four years.

Dukeman.—In Los Angeles, Cal., on Monday, October 23rd, Dr. William H. Dukeman, aged sixty-one years.

Frierson.—In Shelbyville, Tenn., on Saturday, October 21st, Dr. William G. Frierson, aged forty-one years.

Hayward.—In Mt. Clemens, Mich., on Wednesday, October 25th, Dr. Abner Hayward, aged eighty-six years.

Henderson.—In Sarnia, Ont., on Wednesday, October 25th, Dr. William A. Henderson, aged forty-five years.

Jewett.—In Providence, R. I., on Tuesday, October 24th, Dr. Franklin S. Jewett, aged fifty-nine years.

Long.—In New York, N. Y., on Sunday, October 22nd, Dr. Henry D. Long, of Greensburg, Pa., aged forty years.

Maine.—In Springfield, Mass., on Sunday, October 29th, Dr. Frank D. Maine, aged seventy-seven years.

McKee.—In Quito, Ecuador, South America, on Friday, October 20th, Dr. Edward Sydney McKee, of Cincinnati, Ohio, aged sixty-two years.

McMann.—In Gardner, Ill., on Tuesday, October 24th, Dr. William W. McMann.

Plumbe.—In Chicago, Ill., on Sunday, October 22nd, Dr. Edward G. Plumbe, of Dubuque, Iowa, aged seventy-eight years.

Saltenberger.—In Millstadt Township, Pa., on Saturday, October 21st, Dr. John Saltenberger, aged seventy-eight years.

Webster.—In Siloam Springs, on Saturday, October 21st, Dr. J. W. Webster, aged sixty-nine years.

BIRTH CONTROL,*

Its Medical, Social, Economic, and Moral Aspects.

BY S. ADOLPHUS KNOPF, M. D.,

New York,

Professor of Medicine, Department of Phthisiotherapy, New York Post-Graduate Medical School and Hospital; Visiting Physician, Riverside Hospital-Sanatorium for the Consumptive Poor of the Health Department of the City of New York.

When at this very moment across the sea in Europe the best blood of the nations which were heretofore considered the most enlightened, cultured, and civilized, is daily being shed; and hundreds of thousands of young men in the prime of life are sacrificed to the Moloch of war, it must seem a hazardous undertaking to talk of birth control, which means artificial birth limitation, and by some superficial observers is designated as race suicide. I trust, however, that before I arrive at the end of my paper, I will have convinced you that the object of my appeal is not a plea for reducing the population, but for increasing its vigor by reducing the number of the physically, mentally, and morally unfit, and adding to the number of physically strong, mentally sound, and more highly developed men and women.

In accordance with the program outlined, I will deal first with the medical and sanitary aspects of the subject. No one will deny that we occasionally come across a family well to do and intelligent where the parents, by reason of unusual vigor, and particularly by reason of the physical strength of the mother, have been able to rear a large number of children. In some instances all have survived and have grown up to be healthy and vigorous. But these instances are rare, and are becoming more and more so every day. On the other hand, large families, that is to say, numerous children as the issue of one couple, among the ignorant, the poor, the underfed and badly housed, the tuberculous, the degenerate, the alcoholics, the vicious, and even the mentally defective, are an every day spectacle. It is well known to every general practitioner whose field of activity lies among the poor and the above mentioned classes, that the infant mortality among these is very great. The same holds true of the mortality of school children coming from large families among these classes of the population.

Concerning tuberculosis, with which, by reason of many years' experience, I am, perhaps, more familiar than with other medical and social diseases, let me relate the interesting fact that a carefully taken history of many cases has revealed to me that with surprising regularity the tuberculous subject, when he or she comes from a large family, is one of the later born children—the fifth, sixth, seventh, eighth, ninth, etc. The explanation of this phenomenon is obvious. When parents are older, and particularly when the mother is worn out by frequent pregnancies and often weakened because obliged to work in mill, factory, or workshop up to the very day of confinement, the child will come into the world with lessened vitality, its main inheritance being a physiological poverty. This systemic poverty will leave it less resistant, not only to tuberculosis, but to all other diseases of infancy and childhood as well. The morbidity and mortality among these children is greatest when the children are most numerous in one family.

Miss Emma Duke, in the third of the Infant Mortality Series, gives the result of a field study in Johnstown, Pa., based on the births of one calendar year (1911). The inspection was made of the 1911 babies in 1913, so that even the last born baby included had reached its first birthday—or rather had had a chance to reach its first birthday; many of them were dead long before that day. The following is Miss Duke's table showing the infant mortality rate for all children borne by married mothers in Johnstown during that year:

Deaths per 1,000 births in	
Families of 1 and 2 children	108.5
Families of 3 and 4 children	126.0
Families of 5 and 6 children	152.8
Families of 7 and 8 children	176.4
Families of 9 and more children	191.9

Dr. Alice Hamilton, of the Memorial Institute for Infectious Diseases, Hull House, Chicago, made a study of 1,600 families in the neighborhood of the settlement. The following is the table of the child mortality rate of the 1,600 families as published by Doctor Hamilton:[1]

Deaths per 1,000 births in	
Families of 4 children and less,	118
Families of 6 children,	267
Families of 7 children,	280
Families of 8 children,	291
Families of 9 children and more,	303

*Address delivered by invitation at the forty-fourth annual meeting of the American Public Health Association, Cincinnati, October 27, 1916.

[1] *Bulletin of the American Academy of Medicine*, May, 1910; and Miss Mary Alden Hopkins in *Harper's Weekly*.

Many families were found of thirteen, fourteen, and even sixteen members. The largest of all was that of an Italian woman who had borne twenty-two and raised two. The small families of every nationality had a lower mortality rate than the large families of the same nationality. The Jewish families of four and less had the astonishingly low mortality rate of eighty-one per 1,000, while in families of eight and less, the rate rose to 260 per 1,000.

The larger the family, the more congested will be the quarters they live in and the more unsanitary will be the environment. Last, but not least, with the increase of the family there is by no means a corresponding increase of the earning capacity of the father or mother, and as a result malnutrition and insufficient clothing enter as factors to predispose to tuberculosis or cause an already existing latent tuberculosis to become active.

What is the result of this condition in relation to tuberculosis—one single disease? Out of the 200,000 annual deaths from tuberculosis in the United States, 50,000 are children. Of the economic loss resulting from these early deaths I will speak later on, but in continuing along the medical and sanitary lines of my subject, I must call your attention to the fact that according to some authors sixty-five per cent. of women afflicted with tuberculosis, even when only in the relatively early and curable stages, die as a result of pregnancy, which could have been avoided and their lives saved had they but known the means of prevention.[2] Sometimes we succeed in saving such a mother by a timely and careful emptying of the uterus. But an abortion, even scientifically carried out and resorted to only with the view of saving the life of the mother, is never desirable, either for the consultant to advise, nor for the gynecologist or obstetrician to perform; and who will dare to say, even under the best conditions, that this operation is devoid of danger!

What is the explanation and what are the consequences from the point of view of sanitation of the death of 50,000 tuberculous children? They have become infected mostly from tuberculous parents, or tuberculous boarders who had to be taken into the family to help pay the rent. In the crowded homes of the poor there was neither sunlight, air, nor food enough to cure the sufferers, and before they died they became disseminators of the disease. Nearly all of the infectious and communicable diseases are more prevalent in the congested, overcrowded homes of the poor, particularly of those with large families. The propagation of syphilis and gonorrhea by contact infection, other than sexual, can be avoided in the homes of the well to do by enlightenment and the conscientiousness of the afflicted. They are almost invariably communicated to the innocent in the homes of the ignorant and poor. Gonorrheal infection transmitted from parent to child or from one infected member of the family to the other, is responsible, more than anything else, for the 57,272 blind persons in the United States.[3]

The great syphilographer, Fournier, left us the following irrefutable statistical evidences of the seriousness of syphilitic transmission. As a result of paternal transmission there is a morbidity of thirty-seven per cent. and a mortality of twenty-eight per cent.; maternal transmission resulted in eighty-four per cent. morbidity and sixty per cent. mortality; and the combined transmissions are no less than ninety per cent, of morbidity and 68.5 per cent. mortality.[4]

I venture to state here that would or could a syphilitic or gonorrheal parent be taught how to prevent conception during the acute and infectious stages of his or her disease, there would certainly be less inherited syphilis, less blindness from gonorrheal infection; in other words, fewer unfortunate children in this world handicapped for life and a burden to the community.

That insanity, idiocy, epilepsy, and alcoholic predisposition are often transmitted from parent to child is now universally admitted, and corroborated by everyday experience, and by an abundance of statistics. Countless millions of dollars are expended for the maintenance of these mentally unfit. The State of New York alone spends $2,000,000 annually for the care of its insane. Whether sterilization of these people would be the best remedy is a question still open for discussion. The constitutionality of the procedure is doubted by some of our legal authorities. Segregation is resorted to in the meantime with more or less rigor according to State laws. Every year, however, many of the patients who had been committed to institutions for the treatment of mental disorders are discharged as cured. They are allowed to procreate their kind. Would it not be an economic saving if at least the persons whose intelligence has been restored were instructed in the prevention of bringing into the world children who are most likely to be tainted mentally and to become a burden to the community?

The economic loss to our commonwealth from bringing into this world thousands of children mentally and physically crippled for life is beyond calculation. But considering tuberculosis we have been able to calculate at least approximately what it costs. I have stated that 50,000 children die annually from tuberculosis in the United States. Figuring the average length of life of these children to be seven and a half years, and their cost to the community as only $200 per annum, this represents a loss of $75,000,000. Such children have died without having been able to give any return to their parents or to the community. Who will dare to calculate in dollars and cents the loss which has accrued to the community because so many mothers died of tuberculosis when an avoidable pregnancy was added to a slight tuberculous ailment in a curable stage? Who will dare to estimate the cost of the loss of an equally large or perhaps larger number of mothers afflicted with serious cardiac or renal diseases, or frail or ill from other causes, whose lives could have been prolonged had an additional pregnancy not aggravated their condition?

Of the many mothers, married and unmarried, who have become chronic invalids and even lost their lives as a result of having resorted to abortive

[2] C. A. Credi-Hoerder: *Tuberkulose und Mutterschaft*, Berlin, J. Kraeger, 1915.

[3] United States Census, 1910.

[4] Berkowitz: Late Congenital Syphilis, New York Medical Journal, June 17, 1915.

measures in order to rid themselves of an unwelcome child, no statistics are available. If such were they would be an appalling evidence of the great danger of such criminal procedures, and would certainly show the advantage of a more enlightened attitude regarding the means of contraception, at least for the married women who are enfeebled or diseased.

The many diseases I have mentioned whereby children in large families, and mothers because of too frequent pregnancies are carried off to an early grave, are not limited to the poor. In regard to economics, the middle class suffers also. Thus, if even a relatively well to do family begins to increase out of proportion to the earnings of the father, the family will soon be in want and approaching poverty. Less and less good food, less sanitary housing, less care of the children, and more sickness will almost inevitably result. Every sickness or death of child or adult has increased the expenses of the family. There is the doctor's bill, the druggist's bill, and last, but not least, that of the undertaker. A grave has to be purchased. If there have been savings, they are gradually swallowed up, and debts are often contracted for the sake of a decent funeral.

Next to the medical and sanitary comes the physiological aspect of birth control, which can be summarized in a very few sentences. The average mother with two, three, or four children, not having arrived in too rapid succession, say, with two or three year intervals, is physiologically, that is to say, physically and mentally, stronger and better equipped to cope with life's problems than the worn out and weakened mother whose life is shortened by frequent and numerous pregnancies.

What is the physiological effect of voluntary artificial restriction of the birth rate of the offspring? In Holland, where the medical and legal professions have openly approved and helped to extend artificial restriction of the birth rate, the health of the people at large, as shown by its general death rate, has improved faster than in any other country in the world, and at the recent Eugenics Congress it was stated that the stature of the Dutch people was increasing more rapidly than that of any other country—the increase being no less than four inches within the last fifty years. According to the *Official Statistical Year Book of the Netherlands*, the proportion of young men enlisted for the army over five feet seven inches in height has increased from 24.5 to 47.5 per cent. since 1865, while the proportion below five feet two and a half inches in height has fallen from twenty-five to less than eight per cent.[5]

In that enlightened country teaching by the medical profession of the most hygienic methods of birth limitation has enabled the poor to have small families, which they could raise to be physically and morally better equipped than formerly, and what is most interesting to observe is that, whether as a result of this or for some other reason, the families among the more well to do are not nearly as small as in other countries.

In Australia and New Zealand, the means of artificial restriction are in free circulation and the restriction of families is almost universal. Yet these two English colonies have furnished to their mother country in these hours of struggle efficient and physically and mentally well equipped regiments. The soldiers of Australia and New Zealand have shown themselves brave and fearless fighters, and certainly equal, if not superior, as far as physical endurance is concerned, to their English brethren. In the latter country, it is well known, birth control is frowned upon by the legal, any by nearly all the ecclesiastical authorities.

And what of France? Before the present war, Drysdale, in his *Small Family System*, very aptly said: "It has become the fashion to speak of the depravity of France, of her alcoholism, of her disregard for law and order, and of her terrible *crimes passionnels*, and to ascribe to them the falling birth rate. If this was the case, it is obvious that these evils would be most intense where the process had gone furthest, i. e., in the cantons of the lowest birth rate (the French islands of Ré and Oéron)." "The passions of the inhabitants of these islands are very innocent; they are reading and dancing. The dancing, always decent, is the preparation for marriage; illegitimate births are very rare. One could not imagine manners more pleasant or more honorable. Nevertheless the birth rate of these islands is among the lowest. It is because every one there is more or less of a proprietor. Each person has some property to protect; each is ambitious for his children." But we have the authority of Doctor Bertillon, the great French statistician, that it is just in the cantons of these islands that the greatest moral improvement has taken place, and that where the French have obeyed the command to increase and multiply, there alcoholism and crime abound.

Let me quote briefly from an editorial article on contraception which appeared in the *Medical Times* for April, 1916: "France today is presenting her splendid spectacle of utter efficiency to the world because only the fittest of her people have survived, and the chief factor has admittedly been contraception. Surely we have heard the last of the croakers about decadent France. Holland would give an equally good account of herself if the need should arise and for the same reason."

We have already touched in part on the economic cost growing into the millions which accrues annually to the nation because of a high birth rate concomitant with a high infant and child mortality rate. Well may we ask the question whether disease and the deaths of thousands of women and children cannot be prevented by an enlightened attitude toward the question of birth control. Why is it not done? If the millions of dollars expended uselessly, reverted to the nation's wealth, would they not add immeasurably to the health and economic happiness of the nation at large?

And now we come to the social or sociological aspect of our topic, so closely interwoven with economics. That the social and moral life of a smaller family, where the father earns enough to support wife and children, and where the mother may devote her time to the care of them, and where neither she

[5] C. V. Drysdale: *The Small Family System; Is It Injurious or Immoral?* New York, B. W. Huebsch.

nor the children must go out to help in the support of the family, is superior to that of a family with a large number of children where the mother and often the older children must slave, does not permit discussion. The larger the family of the poor, the more child labor, the more disruption and irregularity, and the more frequently we find a lower standard of life and morals in general.

The records of our charities and benevolent societies amply prove that, as a rule, the larger the families are that apply for relief, the greater is their distress.

In answer to a letter containing suggestions on this topic, Doctor Foote, president of the New York Association for Improving the Condition of the Poor, very pertinently said: "The race suicide theory which has been so much exploited of late, is an immense encouragement to the large family idea, and the illiterate are hardly to be blamed if they are misled upon this question. The subject that you discuss is one that is worthy of serious consideration, and that has in the past been treated with an excess of sentiment."

That judicious birth control does not mean race suicide, but on the contrary race preservation, may best be shown by the reports from Holland. The average birth rate in the three principal cities of Holland was 33.7 per 1,000 in 1881, when birth control clinics were started. In 1912, it had fallen to 25.3 per 1,000. The general death rate, however, had dropped in the same period from 24.2 to 11.1 per 1,000, or to less than half, while the two thirds reduction in the mortality of children under one year of age—from 209 to seventy per 1,000 living births—is even more significant.[6]

As a final evidence of the social and economic value of imparting information concerning family limitation, permit me to quote from a personal letter from the great pioneer of this humanitarian movement, Dr. J. Rutgers, honorable secretary of the Neo-Malthusian League of The Hague. The league has been in existence since 1888, and received its legal sanction by a royal decree, January 30, 1895. It has 6,000 contributing members; all information is given gratuitously. As a result of this league in Holland we do not see children dressed in rags as in former years prior to the starting of this movement. To use the venerable secretary's own words:

> All children you now see are suitably dressed; they look now as neat as formerly only the children of the village clergyman did. In the families of the laborers there is now a better personal and general hygiene, a finer moral and intellectual development. All this has become possible by limitation in the number of children in these families. It may be that now and then this preventive teaching has caused illicit intercourse, but on the whole morality is now on a much higher level, and mercenary prostitution, with its demoralizing consequences and propagation of contagious diseases, is on the decline. The best test (the only possible mathematical test) of our moral, physiological, and financial progress, is the constant increase in longevity of our population. From 1890 to 1899 it was 46.20; from 1900 to 1909 it was fifty-one years. Such a rise cannot be equalled in any other country, except in Scandinavia, where birth limitation was preached long before it was in Holland. None of the dreadful consequences feared by the advocates of clericalism, militarism, and conservation have occurred. In spite of our low birth rate, the population in our country is rising faster than ever before, simply because it is concomitant with a greater economic [illegible] movement and better [illegible] hygiene.

To verify these figures statistically, Doctor Rutgers refers to Drysdale's[7] diagrams. The good doctor closes his splendid letter by saying:

> One must have been a family physician for twenty-five years like myself in a large city (Rotterdam) to appreciate the blessings of conscious motherhood resulting in the better care of children and the higher moral standard. And all these blessings are taken away from you by your government's peculiar laws, made to please the Puritans.

To these latter well meaning people and those similarly minded who fear race suicide, particularly a decline of the American stock, I strongly recommend the reading of that splendid address of Professor Charles A. L. Reed, A. M., M. D., former president of the American Medical Association, entitled *The American Family*. In the chapter on The Outlook of the American Family, he pertinently says: "We see in a declining birth rate only a natural and evolutional adjustment of race to environment—an adjustment that insures rather than menaces the perpetuation of our kind under favoring conditions." And concerning underpopulation in general, this distinguished writer says in the same address: "It seems, indeed, to the careful student that the danger to the American family today and still more in the future lies in the direction of overpopulation rather than underpopulation."

According to Mulhall and Reed, the increase in population from 1820 to 1890 was 650 per cent. in the United States (only twenty-five per cent. in the United Kingdom and less than 100 per cent. in France and Belgium). The rate of increase in this country has been vastly accelerated in the twenty-five years that have since elapsed. Our population today of over 100,000,000 has been doubling itself on an average of once in less than twenty-five years since 1790, and it will probably continue to do so in the future. May I say in passing, that in the State of New York we have observed the alarming phenomenon that the proportional increase among the insane is double that among the sane population?

And now I approach the last and most important phase of my subject, namely, the moral, which also means to me the religious, phase of this great problem. Let me say to you, my colleagues, that I approach it with awe and reverence, for I believe I fully understand the import of it.

A quarter of a century of practice among the tuberculous, the rich and the poor, in palatial homes, humble cottages, dark and dreary tenements, and in overcrowded hospitals, has shown me enough to bring to my mind the utter immorality of thoughtless procreation, and my experience has been limited to this one disease of the masses. The tears and sufferings I have witnessed when I have had to decline help because it was too late to prevent the despair of the poor, frail mother at the prospect of another inevitable confinement, and later the sight of a puny babe destined to disease, poverty, and misery, has made me take the stand I am taking today. I am doing it after profound

[6] *Birth Control News*, Cleveland: Birth Control League of Ohio, [illegible], 1

[7] C. W. Drysdale, D. Sc.: *Diagrams of International Vital Statistics with Description in English and Esperanto, together with a Table of Correlation Coefficients between Death & Birth-rates, etc.*, London, Wm. Bell, 162 Drury Lane, W. C. 12

reflection, and I am fully aware of the opposition I am bound to meet. But in my early career as an antituberculosis crusader, I became accustomed to the fate of those who venture on new and heretofore untrodden paths of progress.

What would the moral outcome of birth control, or let us rather say, rational family limitation be, if taught judiciously to those seeking and needing the advice? Millions of unborn children would be saved by contraception from the curse of handicapped existence as members of a family struggling with poverty or disease.

There are hundreds of young men and women, physically and morally strong, who would gladly enter wedlock if they knew that they could restrict their family to such an extent as to raise a few children well. But their fear of a large family retards, if it does not prevent their happiness, and *ipso facto* the procreation of a better and stronger manhood and womanhood. The woman withers away in sorrowful maidenhood and the man whose sexual instincts are often so strong that he cannot refrain, seeks relief in association with unfortunate and often diseased sisters, called prostitutes. The result is a propagation of venereal diseases with all its dire consequences. To an audience composed of physicians and sanitarians I need not say what these consequences are. They involve sterility, physical and mental suffering in the man, or sterility in both man and woman, and according to the severity of the infection—abortion, premature labor, a dead child, or one lastingly tainted with disease.

At times disease does not enter as a factor into the tragedy, but the result is a girl mother, a blasted life, for our double standard of morality recognizes "sin" in our sisters only, not in ourselves. Of her, compassionate tongues only say she loved not wisely, but too well; of him nothing is said at all. He is spotless and virtuous in the eyes of the world and can go through life as if he had never sinned and been responsible for a blasted life or two.

Even our moralists must acknowledge that by an early marriage with a man of her choice, enabled by understanding to limit the number of children, many a girl would be saved from so called dishonor, and in many instances from prostitution One of the strongest arguments of our moralists and purists is that the knowledge of contraception would lead the young to enter upon forbidden sexual relations and become degraded morally. Granted that this may happen in a number of instances, the benefit derived from a diminution of venereal diseases, in a greater number of happy and successful marriages among the younger people, fewer but better and healthier offspring instead of an unrestricted procreation of the underfed, the tuberculous, the alcoholic, the degenerate, the feeble minded and insane, would more than outweigh the isolated instances of sexual intercourse prior to marriage.

After all is said, I feel impelled to plead with all earnestness for the abolishment of the State and Federal laws which make the imparting of knowledge for contraception a criminal offense. I plead for the establishment of free clinics, directed by regular physicians of high repute, remunerated by city or State, who are competent to give information as to birth limitation in cases where they deem the giving of such instructions advisable.

As to the urgency and the wisdom of efforts to change these laws,[8] I am sure that you will be willing to listen to the words of two of our greatest American physicians; first, to those of our venerable Nestor of the medical profession, Professor A. Jacobi, of New York, ex-president of the American Medical Association; secondly, to Professor Hermann M. Biggs, of New York, my own beloved teacher, the distinguished sanitarian and pioneer in the modern warfare against tuberculosis. In his preface to Dr. William J. Robinson's book, *The Limitation of Offspring*, Doctor Jacobi says: "Our Federal and State laws on the subject of prevention of conception are grievously wrong and unjust. It is important that these laws be repealed at the earliest possible moment; it is important that useful teaching be not crippled, that personal freedom be not interfered with, that the independence of married couples be protected, that families be safeguarded in regard to health and comfort, and that the future children of the nation be prepared for competent and comfortable citizenship."

Dr. Hermann M. Biggs, prior to the recent dismissal of the case by Judge Dayton of the Federal Court against Mrs. Sanger for sending information about birth control through the mails, gave to the press the following statement: "I am strongly of the opinion that the present laws in regard to the giving out of information in relation to the governing of infant control are unwise and should be revised. There can be no question in the mind of any one familiar with the facts that the unrestricted propagation of the mentally and physically unfit as legally encouraged at the present time is coming to be a serious menace to civilization, and constitutes a great drain on our economic resources. This is my personal view."

To the foregoing expressions of opinions let me add what one of our most distinguished jurists, the Honorable Judge William H. Wadhams, of the Court of General Sessions, wrote me concerning these laws:

In order to save the State from the burden of large families, where there is no possibility of their being supported and where the neglect which follows often results in their becoming State charges, not only because they are mentally, but often physically unfit to bear the burden of

[8] United States Criminal Code, Section 211 (Act of March 4, 1909, Chapter 321, Section 211, U. S. Statutes at Large, xxxv, 1, page 1,088 *et seq.*), *New York Statute Book* (Section 1142 of the Penal Law). The Federal law prescribed a fine of $5,000 or imprisonment of not more than five years, or both, for any one using the mails to give advice for producing abortion or preventing conception. The New York State law, above mentioned, makes the giving of a recipe, drug, or medicine for the prevention of conception or for causing unlawful abortion a misdemeanor punishable with no less than ten days nor more than one year imprisonment or a fine of not less than $50 nor more than $1,000, or both, fine and imprisonment for each offense. It will be noticed that both laws make the giving of advice for the prevention of conception as great an offense as producing abortion. According to the New York State law, a "lawful" abortion is permitted and not punishable, but to prevent such abortion, always more or less dangerous to life, is not permitted and is punishable by law. In all medical colleges careful instruction is given how to perform the "lawful" abortion. All good textbooks on gynecology describe the operation as carefully as an amputation of the cervix or a hysterectomy; but concerning the advice to give, for example, to the poor tuberculous mother who has had her uterus emptied once so that she may not be obliged to submit to such a "lawful" operation again, our teachers of gynecology and our textbooks dare not say a word.

life, I am of the opinion that there should be some proper birth regulation after a certain number of children have been born, and that, therefore, there should also be some modification of the laws with respect to the giving of information upon this subject. I think the sanitary, medical, social, economic, and moral status of the population would be improved by proper and more general information upon this subject.

Beside the letter from this eminent judicial authority and the strong expressions of opinion of A. Jacobi, M. D., and Hermann M. Biggs, M. D., I have been the recipient of communications from many leading physicians, divines, political economists, and sociologists, all agreeing with me that judicious birth control, under the highest ethical medical guidance, is a national necessity and that our present laws on the subject need urgent revision. For want of space I will mention only the following: Dr. John N. Hurty, secretary, Indiana State Board of Health; Dr. Godfrey R. Pisek, professor of diseases of children, New York Post-Graduate Medical School and Hospital; Dr. J. W. Trask, of Washington, D. C.; Dr. Lydia Allen de Vilbiss, formerly of the New York State Department of Health, now in charge of the division of Child Hygiene of the State Board of Kansas; Dr. Ira S. Wile, editor of *Medical Review of Reviews*, New York; Dr. John A. Wyeth, professor of surgery and president of the New York Polyclinic Medical School and Hospital; ex-president of the American Medical Association and New York Academy of Medicine; Frank Crane, D. D., formerly pastor of the Union Congregational Church of Worcester, Mass., now well-known writer of leading editorial articles; Percy S. Grant, D. D., rector, Protestant Episcopal Church of the Ascension of New York city; Frank Oliver Hall, D. D., minister of the Church of the Divine Paternity, New York city; John Haynes Holmes, M. A., Unitarian Church of the Messiah, New York city; Stephen S. Wise, D. D., of the Free Synagogue, New York city; James A. Field, Ph. D., of the University of Chicago; Irving Fisher, Ph. D., professor of political economy of Yale University, and chairman of the Hygiene Reference Board of the Life Extension Institute; Franklin H. Giddings, Ph. D., professor of political science, Columbia University; William H. Allen, Ph. D., director of the Institute for Public Service of New York City; Hon. Homer Folks, former commissioner of charities of New York, now secretary of the State Charities Aid Association of New York; Miss Lillian D. Wald, founder of the Henry Street Settlement and originator of the work of the School Nurse in New York; A. Melville Dewey, educator and president of the National Society for Efficiency.

I must not fail to say a word about our Catholic friends and those of other faiths who are so strongly opposed to teaching or making public the means of contraception and limiting family increase. Let us have no word of bitterness or reproach because millions of devout Catholics hold these views. Let us not antagonize either priest or Catholic layman, who have a right to their convictions as much as we have to ours. If an enlightened Government will at last permit contraception to be taught where it is likely to be productive of the most good, when in years to come we can show our Catholic brethren that because of birth control resulting in a rational family limitation, we have decreased poverty, disease, and crime, and have produced a better generation of men and women, better equipped physically, mentally, and morally for life's mission—in short, men worthy to be called true citizens of a great republic—then I am sure our Catholic friends will see that after all we have not been wrong, and then they may be willing to follow along the same lines of teaching rational birth control.

I leave it to this distinguished body of physicians and sanitarians either to send a memorandum to the Federal and State governments setting forth the reason for a change of these laws, or, if it is wiser, to form a committee to study the best and most practical suggestions for Federal or State legislatures to act upon.

Dr. William L. Holt, writing on birth control as a social necessity and duty, says: "Conscious and limited procreation is dictated by love and intelligence; it improves the race. Unconscious, irresponsible procreation produces domestic misery, and half starved children. Conscious procreation of human lives elevates man to the gods. Unconscious procreation degrades man to the level of brutes."

May I be permitted to close with what I am free to confess is my innermost conviction? I believe in birth control, that is to say, birth limitation, based on medical, sanitary, ethical, moral, and economic reasons. I believe in it because with the aid of it man and woman can decide when to have a child, work and prepare for its arrival, welcome it as the fulfilment of their heart's desire, watch over it, tenderly care for and educate it, and raise it to be what every child should be destined to be—a being happy, healthy, strong in mind, body, and soul. If we but use our God-given sense to regulate the affairs of Government and family wisely and economically, this great world of ours will be one of plenty and beauty where the good will predominate over the evil, and the children born in it will become men and women only a little lower than the angels—images of their Creator.

16 West Ninety-fifth Street.

COMPRESSION FRACTURE OF THE FIFTH LUMBAR VERTEBRA.

By James K. Young, M. D., F. A. C. S.,
Philadelphia,
Associate Professor of Orthopedic Surgery, University of Pennsylvania; Professor of Orthopedic Surgery, Philadelphia Polyclinic; Orthopedic Surgeon, Philadelphia General Hospital.

Much attention has recently been attracted to displacements of the sacroiliac synchondrosis, and to anatomical and pathological lesions of the lumbosacral and the sacroiliac articulations. Nevertheless, compression or compression fracture, especially of the fifth lumbar vertebra, has not received the attention that it merits. With the exception of the excellent observations of Campbell, Henderson, Sever, and Adams, and the elaborate studies of Hartwell, the literature on the subject is meagre.

Etiology. Compression of the fifth lumbar vertebra is usually the result of a fall, the patient land-

ing violently upon the buttocks in a sitting position, the body being flexed. If the strain is too great for the intervertebral discs, compression results. In this respect it differs from compression fracture in other parts of the vertebræ, which may be due to direct violence as well as to hyperflexion. The position of the fifth lumbar vertebra makes it especially susceptible to such injury; below is a firm unyielding base, and above it must sustain the body weight.

Symptoms. The symptoms of compression are so well given by Hartwell that they need be only briefly repeated: Pain upon movement, local tenderness, protective spasms, limitation of motion, and absence of paraplegia. The x ray findings are all characteristic. If complicated by ligamentous injuries, the patient will have symptoms characteristic of railway spine, reflex spasm upon the slightest movement or touch, etc. If complicated by displacement of the sacroiliac synchondrosis, Kernig's sign may be elicited.

Pain. Pain in the lumbar region is constant and is increased upon any movement which shifts the superincumbent weight of the body. Sitting down or rising from a sitting position increases pain. Changes of position afford temporary relief. Local tenderness is not a characteristic sign, but is more apt to be observed in fracture of the transverse process. Limitation of motion from protective spasm is not a symptom of compression, but is due to ligamentous injury or fracture of the processes or arches and may be absent in compression of the bodies. It is not strange to find the absence of paraplegia or nerve pressure, since the calibre of the spinal canal is not affected. Scoliosis with the convexity toward the compressed side is a constant and important objective symptom. Later a secondary compensatory curve develops. If complicated by displacement of the sacroiliac synchondrosis, we discover Kernig's sign. In the writer's experience there is one symptom which should be emphasized, and that is shock, which is out of all proportion to the amount of injury. One patient was unconscious, with a loss of speech, and inability to stand or walk for a time, on account of the intense pain in the lumbosacral region.

Frequent changes of position have been mentioned. This same patient could sleep only from two to two and a half hours each night for a year following the injury, and then only in a sitting position.

The spinal deformity may be a primary lumbar scoliosis, or a secondary dorsal scoliosis.

Injury to spinal contents. In fractures and compression of the spine, synchronous injury to the cord has been considered a frequent and important sign in establishing a diagnosis. In injuries to the fifth lumbar vertebra greater damage can be borne by the lumbar and sacral nerves if, without subsequent paralysis, the cord itself is compressed and injured. The question naturally arises, Why is the cord not more frequently injured in this condition? The answer is best given by Jacobson:[1] "Being lodged (the cord) in the centre of the column, it occupies neutral ground in respect to forces which might cause fracture. For it is a law in mechanics that when a beam, as of timber, is exposed to breakage, and the force does not exceed the limits of the strength of the material, one division resists compression, another laceration of the particles, while the third between the two is in a negative condition." And so with the spine in cases of compression fracture, one segment, either anterior or posterior, will be exposed to compression, the other to laceration, and the intermediate portion, where the cord is situated, will be in a neutral state.

Disalignment of the spinous processes. This is an invaluable sign and one that is usually present. It is recognized by touch. The impact of the bodies results in a rotation of the spine at the site of the fracture. Below the seat of fracture the tips of the spinous processes may be palpated in a line, which is broken at the seat of fracture, where the tips of the spinous processes will be found to deviate greatly to one side or the other. Localized tenderness is a symptom of great importance, so much so that, when found over the spinal processes, or just lateral to them in the lumbar region, fracture of the spine should always be suspected until examination by the Röntgen rays. Movements of the back are limited and painful, but are no more emphasized than in numerous cases of hypertrophic arthritis.

Among symptoms to be noted are rectal pain and spasm. These have not been especially referred to by other writers of experience, but they form a part of the symptom complex of compression fracture of the fifth lumbar vertebra; but these are also prone to occur in other lesions in the vicinity, as displacement of the latter vertebra, rotation, etc. Paralysis of the sphincter has not been observed in the writer's experience.

X ray diagnosis. This is the final means of determining the presence of compression or compression fracture. In addition, the usual anteroposterior, lateral, and oblique views should be taken, and a detailed study of the region should be made to determine the presence or absence of fracture. The sacroiliac region should be carefully studied, as there is associated at times a displacement on one side. These injuries often go unrecognized for years until the correct diagnosis is established by the x rays. It is then often too late to accomplish much, and this is sufficient excuse for emphasizing the possibility of the existence of compression fracture of the spine. Stereoscopic views are also of some value. Indeed, these patients are often treated for years for suspected lesions of other parts, for instance, a dislocation of the kidney, oophoritis, endometritis, and spasm of the anus. In one patient, irregular menstruation had led to dilatation and curettage, and the removal of one ovary. I have observed an association between displacement of the sacroiliac synchondrosis and displacement of the sacrolumbar articulation, one relieving the strain of the other; the pubic symphysis also took part in mitigating the strain.

DIFFERENTIAL DIAGNOSIS.

A. From fractures of the transverse process of the fifth lumbar vertebra. In this injury we have symptoms of railway spine, but there is never scoliosis or lateral deviation.

[1] Holmes: *System of Surgery*, i. 1883. p. 529.

B. From displacement of the ilium. In this condition there is a history of sudden onset, as when a patient is lifting in a strained position, with no history of traumatism, as in fracture. There may be also lateral deviation of the spine from the beginning of the affection. There is no localized tenderness, no disalignment of the vertebræ; the x rays reveal a displacement upward of the ilium.

C. Rotation of the lumbar vertebræ. In this condition there are lumbar scoliosis, spasm of the spinal muscles, and tenderness over the fifth lumbar vertebra. There are also nerve pressure pains radiating down the limbs, pain in the arms, and general disability.

D. Lateral deviation in Pott's disease. There is always in this disease a marked cyphosis, with occasional abscess formation. The spine deviates to one side from absorption and crushing of the vertebral body and there is marked rigidity from ankylosis at the seat of the disease. Occasionally paraplegia is present.

E. Rickets of the pelvis. In rhachitic deformity of the pelvis, there is often great lateral deviation of the spine in the lumbar and dorsal regions; but always a scoliosis compensatory in character. The pelvic diameters are greatly changed and there are other evidences of rickets in the extremities.

F. Malignant disease of the fifth lumbar vertebra or sacrum. These give excruciating pain in the spine, both local and radiating down the course of the nerves, through the lumbar and lumbosacral plexuses. There is some localized tenderness, and a palpable rounded, oval, bilateral mass, that can be confirmed only by an x ray examination and by laboratory methods, including the Wassermann reaction. Syphilis often occurs in this region and the symptoms are almost identical, except for the laboratory findings. The x ray appearances are quite similar.

G. Arthritis deformans of the lumbosacral articulation. This gives localized pain, stiffness, and rigidity of the spine and pain on motion. There is difficulty in lying down. The x ray examination reveals deposits with some bridging of the intervertebral spaces.

TREATMENT.

Early treatment consists in traction in bed, by the head and feet—the patient being upon a hard mattress, or lying in a body cast, like a Lorenz's shell, or, as it is sometimes called, *Stehbett*. After the symptoms subside, the patient should be fitted with a spinal brace, having lateral uprights and crutches under the arms.

The first three cases here enumerated are instances of compression fractures of the fifth lumbar vertebra with fracture of the transverse process. The fourth case is one of compression fracture without fracture of the transverse process.

Case I. Z. G., aged forty-eight years, fell on a flagstone in a sitting position, February 23, 1914. She experienced severe pain in the lumbar region and lost consciousness. When she regained consciousness the ribs on one side were more prominent than on the other. Her body was "doubled up" as she entered the house, and she was compelled to sleep in a sitting posture for a year, and then only from 11 p. m. to 1.30 a. m. Examination showed the posterior superior spines level and the limbs of the same length. Lateral movements of the spine were slightly limited. There was some rotation of the vertebræ to the left in the lumbar region and to the right in the dorsal region. The lumbar muscles were prominent on the left side. To the left of the sternum the fourth to the seventh ribs were prominent. The left shoulder dropped forward and there was occipital cephalalgia. Pain was complained of all through the lower extremities after the accident. Marked spasm of the anus required divulsion. The x ray examination showed considerable curvature of the spine, an old fracture of the right transverse process of the fifth lumbar vertebra and a fracture of the body with partial crushing of the left side. The patient was treated with a spinal brace, extension, and suspension on a bar. Massage of the back brought about great improvement. Examination by Professor Wendell Reber showed the eye grounds absolutely normal, but she had a high grade esophoria, twelve degrees of latent convergence of the visual axis and a latent hyperphoria or upward deviation of the left eye. She was profoundly neurasthenic and this may have had much to do with her ocular status.

Case II. J. B., a sailor, aged forty years, admitted to my service in the Philadelphia General Hospital. He gave a history of being injured on shipboard four months previously. He slipped, but did not fall, so that he did not strike his buttocks. The affection had been regarded as an intracapsular fracture of the femur. The x rays showed a typical compression fracture of the fifth lumbar vertebra on the right side, with fracture of the left transverse process without displacement upward, but with callous formation about the fracture. The body of this vertebra was tilted forward and the spinous processes were elevated.

Case III. G. H., aged forty-two years, injured February 26, 1913, by falling twenty-five feet out of a tree on the lower part of the spine, striking the buttocks. He was unconscious for a time, and four days later showed peritonitis. He was in bed for three months. I saw him fifteen months after the injury. He complained of pains down the limbs and walked with a limp. He could not raise the right arm and had difficulty moving in bed from side to side. The reflexes were exaggerated on both sides, but there was no ankle clonus and Babinski's reflex was absent on both sides. On the left side there was loss of sensation over the arch of the foot, the inner side of the knee, and over the rectus femoris; but he was sensitive over all the muscles of the back. Kernig's sign was double plus on the right and single plus on the left side. There was sensation to touch in the sacroiliac region on the right side. The abdomen was much swollen, with dullness on percussion over the entire region. The x rays showed fracture of the transverse process of the fifth lumbar vertebra and the process was tilted upward with compression of the body of the vertebra.

Case IV. A. W., aged thirty-eight years, nurse; history of injury of eight years' standing. There was no history of a fall. The injury was brought about by lifting a heavy invalid. Pain was experienced on sitting down or on rising. There was a left lumbar scoliosis, and Kernig's sign was positive on the left side. The x ray examination showed crushing of the body of the fifth lumbar vertebra, with separation of the sacroiliac synchondrosis.

222 South Sixteenth Street.

DIAGNOSIS OF DUODENAL ULCER.

By A. Everett Austin, M. D.,
Boston,
Assistant Professor, Clinical Medicine, Tufts College Medical School; Acting Chief, Medical Clinic, Boston Dispensary; Physician, Berkeley Infirmary.

Duodenal ulcer either is becoming more frequent, or our means of diagnosis more accurate, but every physician who comes in contact with a large series of diseases of the digestive tract must confess inability to disentangle the confusion of symptoms which occur with this disease, and with the so called nervous hypersecretion. As evidence of the former statement, we can only refer to the results of autop-

sies, where, in a lengthy series, duodenal ulcer was only infrequently noted.

For instance, under Chiari, of 3,061 autopsies, duodenal ulcer was found in only 1.38 per cent. Fenwick reports that in 13,055, only thirty-four such ulcers were discovered, or 0.26 per cent. Perry and Shaw report that in 17,652 autopsies, only seventy ulcers, or 0.5 per cent., were found. Weir, of New York, publishes the results of 1,000 autopsies in which only two duodenal ulcers, or 0.2 per cent., were found. In general, upon averaging these and other results, we find 0.365 per cent. of duodenal ulcer. On the other hand, since operation has been more freely undertaken for this disease, based on as complete evidence as could be deduced from symptoms and physical examination, its frequency has steadily increased. Moynihan reports operation in 187 cases in 1908-9 and 115 cases in 1909-10. William J. Mayo reports 152 cases previous to 1906, and 401 from 1906-1911. Why the section statistics should differ so from those obtained by examination *in vivo* has no plausible explanation.

It is conceivable, however, that a duodenal ulcer may spontaneously undergo so complete a cure that the scar tissue which is left may be fully absorbed, and hence escape the attention of the pathologist. The operation, naturally, takes place during the period of activity, and we are surprised at the unerring accuracy with which a competent surgeon, with hands incased in rubber gloves, can detect indurations in the duodenum resulting from this form of ulcer.

The practitioner, however, has to do with an entirely different phase of the problem. It is all right for such an authority as Moynihan to declare that he has been able to verify by operation almost all of the cases of duodenal ulcer which he had diagnosed, but the average practitioner would certainly lose ground in the confidence of his clientele if he recommended operation based upon his diagnosis, and in many of the cases, operation was found to be unnecessary. On the other hand, it is often dramatic to see the number of patients who have suffered for years from this disease, passing from physician to physician, and being treated for nervous indigestion, neurasthenia, etc., when the basis of all their suffering is an unrecognized duodenal ulcer. How, then, are we to avoid sins of omission and commission?

Let us first analyze the symptoms of which the patients suffering from this disease as well as from nervous hypersecretion complain, because, unfortunately, the manifestations of a comparatively simple functional ailment and of an ominous disease are extremely similar. These symptoms are: Periodicity of suffering, interrupted by intervals of comparative freedom, an excellent appetite, appearance of discomfort or pain some hours after the meal, and relief from distress after food is taken. In the first place, through complications brought about by adhesions, it is difficult, without leading questions, to obtain from the patient a clear succession of these symptoms. At first, unquestionably, the pain and discomfort are long delayed after food is taken, but there comes a time when patients insist that with either affection the pain is continuous and the former relief from food is either restricted or entirely absent. In general, we can always learn that the suffering has persisted for a long time, some declare for years, and in many instances its progress has been so gradual that the patient cannot remember its original onset. Nor is this discomfort always designated as a pain, but sometimes as pressure or fullness, particularly when the stomach is empty instead of filled, as is common with sufferers from myasthenia. Others describe their feeling as that of constant hunger, which is stayed only for a short period by taking food, a species of bulimia; and declare that their stomachs empty quickly, though even where undoubted ulcer exists, this can be disproved either by the use of the tube or by x ray examination. At least in such cases, except where adhesions have formed, we never have the overwhelming pain that is experienced with gallstone colic.

With reference to the character of the pain in duodenal ulcer and hypersecretion, there are included here a few of the actual expressions of patients who have suffered from these disorders and in whom the former affection has been demonstrated by operation:

No. 611. Pain in pit of stomach, accompanied by vomiting, two to three hours after food is taken; relieved by soda and by eating. Never occurs in the morning.

No. 720. Dull pain two to three hours after eating; relieved by food. Pain awakens at three or four o'clock in the morning with sour eructations.

No. 658. Pain occurs only in the evening and early morning.

No. 129. Pain in pit of stomach extending to back, three or four hours after meals; relieved by food.

No. 560. Pain in pit of stomach occurring mostly at midnight; relieved by food.

No. 166. Pain three or four hours after eating; relieved by food or hot drink.

On the other hand, in cases of pure hypersecretion, where neither the presence of occult blood nor x ray examination could verify the presence of an ulcer, we have the following descriptions of the pain:

No. 552. Severe pain at two or three a. m., which is relieved temporarily by food.

No. 225. Pain may come directly after food or several hours after; when occurring late, relieved by food.

No. 739. Pain arouses from sleep in early morning, with occasional vomiting; relieved by food.

No. 172. Pain under the breast bone four hours after meals; occurs much oftener after a large meal.

From these brief reports, which comprise only a few which could be cited, we can plainly see that as to character and period, the pain does not vary. The appetite remains excellent in both conditions, in fact, is exaggerated, and periods when the stomach is empty are times of great discomfort to the patient, who hastens to refill his stomach. It will also be noted from these descriptions that the period at which the pain occurs in the night varies greatly. When these are analyzed, however, we learn that the patient who indulges in a hearty meal at six or seven o'clock in the evening finds that his attack occurs in the early morning, while he who indulges in an ordinary light New England supper, experiences his distress late in the evening or about midnight.

Schriiver states that the severity of the night pain has considerable diagnostic value; the more severe

and frequent it is, the greater is the severity of the lesion when ulcer actually exists. When pure hypersecretion is present, however, the pain can often be alleviated by taking a light meal rather than a heavy dinner. Another feature of both diseases is their characteristic periodicity. In true duodenal ulcer, however, most patients report attacks occurring constantly in fall and spring, while with hypersecretion of nervous origin, periods of mental distress or worry bring on an attack. A traveling salesman under my care, was always plagued by this latter affection whenever he started on one of his long business trips which usually lasted from four to six weeks, during which strenuous efforts were demanded of him on account of competition. At home, he was always free from this discomfort.

Acid eructations may occur with both conditions, which may be exaggerated until actual vomiting takes place, but an occasional opportunity to examine the vomitus has demonstrated almost always a pure gastric juice without food fragments, so that they are not induced by pyloric stenosis or spasm.

The site of the pain has no diagnostic value since some describe it as extending through to the back; others as passing up along the chest on both sides; while in one instance, in which operation proved the presence of duodenal ulcer, the pain was invariably situated under the sternum.

As the symptomatology of duodenal ulcer is somewhat vague, and as already stated, coincides so closely with that of pure gastric hypersecretion, unless we agree with the Mayos, that the hypersecretion is always the outcome of an ulcer or ulcer scars, we are forced to rely almost wholly upon physical examination for the differentiation of the conditions.

As regards the patient's general condition, unless he has refrained from eating for fear of exaggerating the pain, which rarely occurs, because instinctively he soon learns that food eases the pain, we find the sufferers from either condition well nourished, in fact, in two instances under my observation, they were obese from the frequency and the quantity of the food which they had taken to satisfy the spurious hunger. Only rarely do we find a patient blanched and anemic from repeated minute hemorrhages into the intestinal tract.

The tender point which is so frequently described, has not been discovered at all constantly by me. In fact, instead of the localized tender point, as described, midway between the sternum and the navel and a little to the right, various forms of tenderness have been found in cases in which operation showed an undoubted duodenal ulcer. In one instance, the painful point was at the right of the median line just above the navel; in another in the epigastrium to the left of the median line at the level of the eighth rib; in another, the tender point was just under the xiphoid, and in still another, over McBurney's point. In all others of the thirteen cases, the records report no tenderness whatever. The rigidity of the right rectus has also been adduced as a diagnostic point in the detection of duodenal ulcer, but in my series of twenty-five cases this peculiarity was never discovered.

Increased acidities, either alimentary or due to the presence of highly acid gastric juice in the fasting stomach, are well recognized features which are rarely missed, particularly the former. While some authors report undoubted instances of duodenal ulcer where the acidities are normal or sometimes diminished, this has not been my experience. In all of the thirteen cases operated in, in which estimations of the gastric acidities were made, there was no exception to the presence of a hyperchlorhydria. These acidities, as a general rule, run higher than fifty and eighty for free and total, but two instances were found where the total acidity ran as high as 120 and 150. In the cases not operated in, the same rule holds true. While these latter may be regarded as instances of pure hypersecretion, yet the presence of occult blood, characteristic pain, and the results of the x ray examination indicate that they were unquestionably cases of duodenal ulcer. These examples, of course, were based upon the alimentary hypersecretion and have nothing to do with the continuous secretion which was found in many cases. In practically all instances, too, these high acidities were accompanied by an increase in the total volume, the gastric contents often running as high as 200 to 250 c. c., hence the conclusion must be drawn, based upon this limited number which, of course, bears no relation to the enormous number which the Mayos and others have collected, that an alimentary hypersecretion is always associated with duodenal ulcer. Unfortunately, however, while duodenal ulcer is associated with hypersecretion, the latter does not by any means always indicate an ulcer, so that the diagnostic value of this symptom is much impaired.

With reference to the continuous secretion, we find among the thirteen cases, six in which the fasting stomach always contained a larger amount of gastric juice than normal. Just what the normal amount is, has never been fully determined, but for comparison, a minimum of thirty c. c. was selected, and all amounts beyond that were regarded as hypersecretions. Among the twelve cases not operated in, there were also found six characterized by this fasting hypersecretion, making practically half of the total accompanied by this persistence of gastric juice after the food had left the stomach, as shown by careful microscopic analysis. Again, there is a distinct difference between the increased acidities associated with myasthenia, in which the solid residuum of the gastric contents forms half or more of the total. In many instances, however, though not all, record was made of the relative amount of solid material, as determined either by sedimentation or by the use of the centrifuge. Of the cases operated in, four were found in which the solids were as low as 1/12, 7/100, 1/6, and 1/8, while the others did not differ from the normal. This was also true of the cases not operated in, hence it seems possible to conclude that, with a large amount of content withdrawn with high acidities and small residue, we have a much greater probability of some organic lesion acting as an irritant, than with high acidities with small volume and large residue.

The next main suggestive diagnostic point is the presence of small quantities of blood in the

digestive tract. Of course, where the ulcer is situated in the first part of the duodenum, blood is rarely found in the gastric contents, and even when blood is found, its availability for diagnosis is much impaired from the fact that it is often produced by the slight mechanical lesions caused by the tube. When we examine the feces for the detection of blood, after the usual precautions of excluding hemorrhoids, clearing out the intestinal tract by a laxative, and demanding a three days' meat free diet, and find blood, in my estimation it is one of the most suggestive of all the varied points which lead to the diagnosis of duodenal ulcer. Never, in my experience, has a purely functional gastric hypersecretion been accompanied by chemical blood in the stool, so that while duodenal ulcer may unquestionably exist without minute hemorrhage into the intestinal tract, its presence, associated with the other main symptoms of characteristic pain, fasting discomfort, hypersecretion, and x ray findings, is almost pathognomic of duodenal ulcer.

Of the thirteen cases operated in, occult blood was found in six, which gives a ratio much greater than that reported by other investigators. Unfortunately, however, no distinction is made by various authors between visible blood in the stool or the so called "tarry stool," and the chemical blood, always minute in quantity, determined by reagents. Moynihan reports occult blood in only fifty per cent. of his cases, Perry and Shaw in fifteen per cent., and Fenwick in forty per cent.

When we depend upon such gross hemorrhages as produce "tarry stools," the percentages must be vastly less than in the detection of occult blood; hence Mayo regards this symptom as possessing the least significance for the diagnosis of duodenal ulcer. On the other hand, if the feces from a patient suffering with this disease are examined persistently over some little period, it will rarely happen that no evidence whatever of blood is found. It is conceivable, however, that an ulcer may heal so that no active oozing takes place and still may produce symptoms through adhesions, which renders the life of the patient miserable. Then, again, there may be periods during which no discomfort is experienced, when minute traces of blood in the stool are not found. During an exacerbation, however, it rarely happens that a careful, persistent search for blood is not rewarded by success.

Of my cases not operated in, twelve in number, occult blood was found in ten. The only explanation which can be offered for the disproportion between these two groups is that the group operated in was of much greater chronicity, a factor which often induced the patients to submit to operation on account of the long duration of their illness and their desperation in search of relief. Many of these cases, too, at operation showed that adhesions caused the greater part of the discomfort and that the ulcer was probably not in a state of activity. In my estimation, the presence of occult blood will always strongly substantiate the diagnosis of ulcer, while its absence does not necessarily exclude ulcer, when backed up by other evidence.

As to the value of x ray examination, many different opinions are expressed. Some would base the diagnosis almost wholly upon distortions found in or about the so called "Bishop's cap," while others demand in the x ray examination evidence of early rapid motility and exaggerated peristaltic waves. It was found that of the thirteen cases operated in, seven had had x ray examinations; of these, six confirmed the diagnosis of duodenal ulcer made upon other evidence and substantiated by operation, while one proved entirely negative, though the scar was clearly evident when the abdomen was opened. One case not included in this list was diagnosed as ulcer largely on account of the x ray examination, but at operation there proved to be a kinked and twisted duodenum due to adhesions to the gallbladder. It seems, however, that we are not justified in recommending operative intervention unless the assurance of röntgenological investigation is given the patient. In my own cases, where such an examination was not made, other evidence already mentioned was so positive that the former seemed superfluous, while the expense to people of limited means is no inconsiderable matter. Of the cases not operated in, five had x ray examinations with three negative results and two positive, but identification of the ulcer was wanting because the abdomen was not opened.

From review of the factors included in this short article, it seems that a diagnosis of duodenal ulcer must be based largely upon the four factors of periodical and characteristic fasting discomfort, if not pain; on the presence of hypersecretion, particularly of the alimentary variety rather than the continuous; on the presence of occult blood in the stool; and on distortions of the first part of the duodenum, as shown by the radiogram. A short perusal of any series of case histories will soon show that all of these are practically never found in any one case. When, however, any two or three are evident, we may well forego the presence of the fourth factor. The relative value of the history, of the character of the pain and its intermissions, and the detection at some time of occult blood in the stool, appears to me to be of the greatest importance. On account of the close similarity of symptoms, as explained, of duodenal ulcer and functional hypersecretion, the former lose much of their significance and dependence must be placed more upon physical signs than upon symptoms, and, as hypersecretion is present both as a functional disorder and as the outcome of ulcer, we are driven to the conclusion that occult blood in the stool and the distortion of the duodenum shown by the x ray examination are the positive signs upon which we must largely base our diagnosis.

As far as the differential diagnosis is concerned, there is probably no condition which so closely simulates duodenal ulcer as cholelithiasis. Reference is not made to the typical attacks of gallstone colic with vomiting, but to the advanced forms, where adhesions have taken place between the gallbladder and the duodenum. It is common, too, to find in cases of gallbladder involvement, by reflex action, the same hypersecretion which we may find with the ulcer, and, secondly, there is often the tender point so characteristic of the latter. The periodicity of attacks of cholecystitis is well known. In my experience, one of the most distinctive points of difference between these two conditions is the slight

trace of bile found in the urine when the common duct and gallbladder are involved. Still, with the greatest effort at learning the truth, mistakes are often made. Reference has already been made to the instance where a primary cholecystitis produced such marked symptoms of duodenal ulcer by adhesions to the duodenum that the operation was undertaken with that mistaken diagnosis, only to find that the primary condition was an inflamed gallbladder with several small stones. On the other hand, a man presenting himself with jaundice following an attack of typical pain, though a diagnosis of cholecystitis was made, was shown at operation to have a duodenal ulcer which, by causing adhesions to the gallbladder, had produced obstruction in the common duct. In typical gallstone colic, however, the pain reaches a severity which is never found with duodenal ulcer. Another characteristic feature is that the distress produced by duodenal ulcer can generally be allayed by food or an alkali, or, as one patient puts it, "the employment of a hot drink," but these means are never successful in checking a gallstone colic. Again, a marked distinction can be made by the common experience that icterus, or at least bile in the urine, occurs with cholecystitis, while blood in the feces is found more particularly with duodenal ulcer, although there have occurred in my practice cases of cholecystitis associated with arteriosclerosis, where occult blood was found repeatedly in the stool, owing probably to the rupture of some small arteriole in the intestinal tract.

The distinction between gastric ulcer situated near the pylorus, and duodenal ulcer, is often impossible; in my estimation, it is a mere refinement of diagnosis to reach such a decision, so that, like many practitioners, we merely refer to the lesion as a gastroduodenal ulcer, leaving it to the surgeon to differentiate. The ulcer inside the pylorus, or, in other words, on the gastric side, has been found by me to be much more likely to produce gastric stasis either through the redundancy of the scar tissue or by means of the pyloric spasm which so often accompanies it. As to the delayed pain or fasting discomfort, there is little or no difference whether the ulcer is inside or outside the pylorus. This does not exclude the possibility of saying that the ulcer is of gastric origin when it is situated in the lesser curvature or in the fundus, where, unquestionably, pain occurs much earlier.

Another difficulty which has apparently confused many diagnosticians is the differentiation of duodenal ulcer and appendicitis. In more than half of the operative cases which have come under my observation, the appendix had been removed without more than temporary relief of pain and discomfort. In many of the reports which have been received in regard to the condition of the removed appendix, it is plainly indicated that there was not a distinctly diseased organ; such terms as "moderately enlarged," "slightly congested," being employed to designate its condition. Whether this similarity is due to the reflex relation of the plexuses by which pressure applied above the navel causes pain at the appendix or not, or whether there is an associated causal relation between mild disease of the appendix and a duodenal ulcer, as has been held, is not certain. At least, whenever the appendix has escaped removal and patients are operated on for duodenal ulcer, the appendix, at my suggestion, has always been removed.

Moynihan calls attention to this associated lesion of the appendix and the duodenum, considering it probable that the duodenal ulcer is secondary to the invasion of the appendix and due to a toxemia arising from the latter. On the other hand, Schrijver declares that, when both pathological conditions are found, the appendicitis is more likely to be secondary or oftener a coincident affection. The conjoint condition of duodenal ulcer and inflamed appendix has not been found by him with the frequency that it has been by Moynihan. My own opinion has always been that the diagnosis of diseased appendix is often made in error on account of the reflex relations of the plexuses involved, and that unless undoubted evidence of disease in the right lower quadrant is present, in the form of tenderness at McBurney's point, rigidity of the right rectus over it, and attacks of slight rise of temperature, it is much wiser to let the surgeon make the median incision and examine the region of the duodenum, at the same time removing the appendix, if the duodenum is found normal. At least, confusion occurs only with the so called chronic condition or appendicitis larvata.

110 Marlboro Street.

THE VALUE TO THE OPERATING SURGEON OF A THOROUGH UNDERSTANDING OF THERAPEUTIC AGENTS.*

By Albert Vanderveer, M. D., LL.D., F. A. C. S.,
Albany, N. Y.

I feel it proper to preface with some remarks the paper I am about to present. The older I grow, and now that more time is afforded me to review the results of a rather active life, the less hope I have of contributing something of value to the members of this society. Since the organization of the society I have believed it possible for your papers and discussions to be of great value to the busy operating surgeon, and in this I have not been disappointed. In our early study and diagnosis of abdominal lesions, the physician, or general practitioner of olden days, and the surgeon accomplished much in the joint study of their cases, but not until the introduction of aseptic surgery did the operating surgeon become a factor of therapeutic importance. In those memorable periods, however, one great advance was made, when, in consultation, the physician and surgeon combined in one strong effort to study the new conditions of abdominal work. Also, at this time, laboratory investigations developed, and, as a result, a more perfect knowledge of their importance. In an early announcement of one of our annual meetings it was stated, in addition to the list of valuable papers, "let us have your suggestions regarding any subject you may believe to be of value to the society." I consider this one of the most impressive appeals given by any of our National

*Read by title at the seventeenth annual meeting of the American Therapeutic Society, Detroit, Michigan, June 10, 1916.

associations, and here may I be permitted to say: That in general surgery the men of the future who accomplish success will be those who give the best that is in them to the study of surgical bacteriology, and that, closely following them, will be those who work in the atmosphere of this society. It is difficult for me to express how much I regret the tendency, in some of the younger men in our profession, in the handling of their patients, or in getting the histories, to frequently lose all interest in the case when once they have touched upon a surgical lesion and have said, "this is a case for the surgeon." In a certain percentage of cases more persistent investigation would have demonstrated that therapeutic measures following a correct diagnosis, would have obviated the necessity for an operation. The operating surgeon is, at times, placed in an embarrassing position, when the attending physician, having assured the family that an operation was absolutely demanded, finds on a more prolonged study of the case that therapeutic measures alone are necessary; or—another dilemma—when hurriedly called to do an operation, he finds it unnecessary and that the therapeutic elements in the case have been sadly neglected. Alas! too often is it a source of great distress when the surgeon comes in contact with conditions that might have been cleared up by proper therapeutic measures.

In these remarks I offer no excuse for the failure of the operating surgeon thoroughly to examine the patient upon whom surgical intervention is about to be employed, nor do I wish to convey the impression that in any way I am depreciating the earnest, painstaking investigations of our splendid physicians of today. If we have a criticism to make at present, in medicine or surgery, it is that we are prone to discredit our efforts and to forget that the enemies of our profession—disease and death—never relax their tendency to destroy.

Here let me say that no surgeon is free from errors in his diagnostic work, but also allow me to make this plea, that we continue our team work and not forget the mistakes in diagnosis that are now being brought so prominently to the front by our laboratory reports. Since my first visit to the Mayo clinics I have often thought of the thoroughness of their examinations, and the completeness of the sequence whereby each doctor has his special work, leaving no doubtful points of diagnosis when the case finally reaches the operating table.

At my time in life there is much, very much, to be recalled, not only in preventive medicine, but in the more efficient application of therapeutic remedies, as we know them at the present time. It is not out of place to refer to serious operations necessitated upon some particular part of the human system, in which the earlier application of rational therapeutics, as we understand them now, would have relieved much suffering. How often the simple alveolar abscess—particularly in the child—has been allowed to go on until more serious necrosis followed.

It took us a long time to understand that a number of our joint troubles arose from invasion of the system through the tonsils, and today, although no subject has received more attention in our laboratories, by clinicians and surgeons, than suppuration, what baneful influences continue to attend the formation of pus. Inflammatory processes today, with the methods of examining the secretions, the blood, and especially the genitourinary tract, the biliary system, and other important organs, afford us more accurate diagnoses, and the various new therapeutic methods have relieved much suffering, and prevented serious organic changes. Pus, however, maintains the same vicious influence as of old. We have but to study the wounds now occurring in this terrible European war to be convinced. The therapeutic value of the continuance of the methods to which I have referred, and the more thorough investigation of the blood, in aiding location of the foci of pus, cannot be overestimated. The same statement applies to x ray work and a host of similar aids to the application of therapeutic remedies. I am sure that some of the criticisms of today will be condemned, so far as they tend to undermine our confidence in past bacteriological and therapeutic measures.

Although the class of cases to which I am about to refer were the easiest for me to select from my histories, I might say that today it would be difficult to give, in the same period, a like number, owing to advanced therapeutic knowledge, yet their symptoms corresponded so nearly to those of the disease suspected that I believe they are of sufficient importance to be embodied in this short paper; and to lead to conclusions that may be of service to children, with whom my advancing years bring me more and more in love and sympathy.

It is difficult to get subjective symptoms from children, and unless we are exceedingly careful we fail to recognize the true condition. Occasionally the child is treated for a supposed rheumatic condition, when, in reality, joint changes are already present, and an error is committed in not getting a consultation sufficiently early. These cases sometimes reach us in a lamentable condition. Yet it is desirable not to put a child under the strenuous treatment required in acute surgical disease, unless it is positively indicated.

There are many advances in my profession I review with the greatest of gratitude, among them a better and increasing knowledge of reflex conditions. In the cases I am now reporting it was plain that the condition of the system was manifested in the urine and other secretions, correction bringing rest and comfort to the little one, and relief to the anxious parents. Examination of the urine, feces, tonsils, and teeth should be made with great care in all cases pointing to joint trouble in children or in adults.

As a profession we have, for many years, felt the necessity of relieving reflex irritation early in hip-joint disease especially, and men of my age will remember how enthusiastically the late Doctor Sayre emphasized the adherent prepuce and congenital phimosis as an element of irritation that must always be eliminated before putting such cases upon mechanical treatment.

In the five cases I report each presented such characteristic symptoms as lameness, nocturnal pain, pain on examination of the joint, fixation with contraction of the limb, increased pain on pressure of the head of the bone into the acetabu-

lum, with other marked signs, and general illness of the child, so that it seemed absolutely necessary, as the opinion of two of the physicians in charge was expressed, that the child should be put upon treatment for acute inflammation of the joint. As will be observed, in one case a splint was actually procured, with the intention of placing the child upon that line of treatment.

After the study of these cases I not infrequently heard the remark, through some of my patients, that there were doctors who considered me a crank on uric acid in the urine and diet. Perhaps there may have been an atom of truth in the statement, but what better therapeutic aids have we had in the past few years in the treatment of blood pressure, with its associate conditions, than those derived from understanding of acidosis and diet?

Case I. K., aged twenty months, a strong, well developed girl, walking when a year old; active and energetic in every respect. About August 1, 1892, the child showed a slight hesitation in her walk with the right leg. This early attracted the attention of her trained nurse, and the physician of the family was called to see her. There was no history of traumatism. The child could not tolerate having the leg extended, was fretful, did not sleep well at night, and was petulant during the day; there were some digestive disturbances, and the danger of hipjoint trouble was pointed out. When I examined her, August 2d, there was flexion of the thigh upon the abdomen, and characteristic symptoms pointing to hipjoint disturbance. The child cried very much indeed when approached, particularly when an examination was made. She was ordered kept absolutely quiet, no effort made to take her out in the carriage; she very reluctantly consented to be lifted from the crib to the sofa, and was contented not to he disturbed in any way. When moved, she complained of pain in the joint. She was an only daughter in a representative family, and the intimation of hipjoint trouble caused great sorrow, as an aunt had died of tuberculosis at an early age. On examination of the urine, made on my third visit, and at a time when the wire breeches had been ordered, I found a marked condition of uric acid. The term, acidosis, would not have been inappropriately used.

I immediately put her upon a preparation of bicarbonate of potassium, and ordered her to drink freely of lithia water, which she was very willing to do. She soon showed signs of improvement, and in two weeks made a complete recovery, having no return of symptoms later on, nor any indication of having suffered as she did for a length of time. Her urine has been examined a number of times, and there is always a trace of uric acid, but she drinks pretty continuously of lithia water and shows no evidence of rheumatic trouble elsewhere; is a well, active, healthy young woman.

Case II. November 7, 1895, I was called in consultation hy the family physician to see Master S., aged eighteen months, who was, apparently, suffering from marked lesions about the left hipjoint. He had shown somewhat similar symptoms previously, had been circumcised for a congenital phimosis, and improved after that, but the parents were on the alert and promptly advised their physician when they observed any untoward symptom. He had been ill for nearly two weeks when I saw him, crying out in his sleep at night, could not be handled with comfort, objected to the approach of his nurse, or to any attention on the part of his mother, presented a rise in temperature, with loss of appetite, and looked sick. The objective symptoms were really deceptive. There was some contraction of the thigh upon the abdomen, apparent pain in every effort to straighten it, fixation of the joint when bringing the leg down to the level of the mattress, the spine was elevated, and there were symptoms of acute inflammation of the joint. He received a thorough examination, although somewhat unsatisfactory, owing to his crying and struggles, a condition now lessened for a moment by administration of an anesthetic. Upon inquiry, I learned that his urine had not been examined. This was done and it was found to contain a large amount of uric acid. It was noticed he was not voiding very much, and in urinating he was quite distressed.

He was put upon a thoroughly alkaline treatment, with marked benefit, ultimately making a good recovery, and within a short time. No mechanical contrivance was used. He is now a fine, robust, and energetic man, with no return of his trouble. His mother and himself thoroughly believe in careful diet, and free drinking of water.

Case III. September 10, 1896, I was requested by the family physician to see Master S., aged two years. The patient had suddenly been seized with pain in the left hip, and the doctor feared that incipient disease of the hipjoint was developing. The little fellow had a slight congenital phimosis, which was relieved at once, but his pain continued and his inability to sleep disturbed the household. In all ways he presented an alarming sickness. He showed rather more characteristic symptoms than either of the previous patients. On my second visit, I secured a specimen of his urine and found a very pronounced acid condition, with a great deposit of uric acid and triple phosphates—lithemia well marked.

After letting him drink very freely of lithia water, which he took willingly, keeping him quite faithfully upon the potassium carbonate, which he also took readily, and after having given him small doses of calomel, the little fellow improved, made a complete recovery, and today is an active, healthy man.

Case IV. On March 12, . . . Master B., aged eight years, an active, healthy boy, attending the primary department in school, was supposed to have been injured in coasting. Soon after, he complained of lameness, which, in a few days, developed into the characteristic symptoms of disease of the hipjoint, and the consulting surgeon felt the necessity of placing him in bed with a weight and pulley. The child was brought some little distance to me for consultation, and while there were many of the characteristic symptoms of early disease of the hipjoint, yet examination of his urine presented the same history that previous cases reported in this paper had shown. After a pretty vigorous alkaline treatment, he made an exceedingly prompt recovery, and remained well without return of his active symptoms.

In considering these cases we find a number of interesting conditions. Rheumatism in children, as most of the authorities agree, when affecting the joint, is apt to be slight. It is true the stiffness and tenderness may be well marked, and that the inflammation may be limited to a very few joints, but I do not now remember any reference to cases where the affection seemed to be confined so decidedly to one joint, and that the hip. Then the treatment must claim consideration, for it seemed in the most pronounced manner to grant relief, when prescribed on the basis of a rheumatic trouble—an excessive amount of uric acid in the system.

The length of time since the attack certainly leads us to consider that there were no real inflammatory conditions causing organic changes. No lesions whatever were left in any case, nerve, muscular, osseous, or other.

This paper is a slight contribution to a class of cases to aid us somewhat, perhaps, in the diagnosis of a condition that causes great anxiety, one requiring positive treatment if it is a true surgical lesion.

Recently, in the *Lancet*, Langmead, referring to

rheumatism in children, said: "About one in every fifteen London school children is rheumatic, and, if poor, he does not get adequate treatment. The disease is left to smoulder on. There should be routine examination of children from this standpoint."

These cases are in line with that important study we are now attaching to our surgical investigations, i. e., end results. My fifth case, however, is one that introduces the element that will probably never be excluded from the ultimate conclusions.

Case V. Miss C. H., aged twelve years, was treated for some little time by one of the ablest men in our profession, a diagnostician of rare skill, and exceedingly painstaking. When called to see this child, he found, in his careful examination, that the left hipjoint seemed to be more particularly involved, also in her walk; there were some nocturnal pains. He went over the case very thoroughly and put her upon a line of treatment for a rheumatic condition, although the urine exhibited little uric acid. No great improvement followed. A few weeks later, June 24, 1912, I saw the case with him in consultation, and the contraction of the limb, together with other symptoms, led us to believe that hip trouble might be developing. The patient was put upon Hutchinson's treatment, with crutches, the shoe of the well leg elevated, a weight applied to the shoe of the suspected limb, and she was allowed to get about, her general medical treatment being continued.

After a few months it was a delight to all to note her symptoms had quite entirely disappeared. At the end of six months, she was able to get about without the crutches; the flattening of the hip gradually disappeared, and she has remained well since, developing into a fine, healthy girl, but with this criticism in the mind of the older physician, living in an adjoining city, who saw her two or three times during her early illness—that the surgical treatment had little to do with her recovery.

May it not be said, there will always be a borderline of cases in which both medical and surgical diagnosis may be questioned?

28 Eagle Street.

POST PARTUM SEPSIS.

By Albert M. Judd, M. D., F. A. C. S.,
New York,

Gynecologist, King's County, Jewish, and Long Island College Hospitals; Consulting Gynecologist, St. Joseph's, Far Rockaway, and Swedish Hospitals, and East New York Dispensary.

I wish to present the records of a list of 100 cases of post partum and postabortive sepsis which occurred in my service in two hospitals, and from which I have elicited many interesting points. My plan in the arrangement of this list has been to place the prominent features under headings, as follows: 1. Number of days in the hospital; 2, hospital diagnosis which was placed on the chart on the discharge of the patient; duration of pregnancy, and the days post partum or postabortive; 3, treatment before admission; 4, treatment in the hospital; 5, under remarks I have placed morbidity, the change of symptomatology due to change of position or vaginal examination, and the result on discharge; 6, laboratory findings. Under laboratory findings I have the results of blood cultures, and in a few cases the findings of colon bacilli in the urine. Leucocytosis and the differential I have not given, but will simply state that the leucocyte count varied from eleven to 40,000, and the differential from eighty to ninety-five. These cases varied; first, from a class which may be spoken of as sapremia; second, the more dangerous toxemias, which formed the great majority; third, a minor number of bacteriemias. Most of the sapremic cases went along without further trouble than was shown by a rise of temperature, which dropped in a few days and the case proceeded to a moderately quick recovery. The toxemia cases varied in symptomatology according to the local lesions and the result of the toxemia. The bacteriemia cases were not uniformly fatal as will be seen from a further analysis. Unfortunately the blood cultures were studied only for aerobic bacteria, not anaerobic. The cases varied in length of time of illness, one case of bacteriemia being fatal two days after admission to the hospital, and one case of pyemia is credited with a stay of ninety days. Every time I have reviewed this list I have been able to pick out something new from it, and I recommend it for study.

It is my opinion that these two conditions, especially that occurring post partum, cause the general practitioner more annoyance and worry than any other condition with which he is confronted. He is subjected many times to unjustifiable pressure from the family and friends. Often for fear of criticism he is led to adopt active treatment which his own better judgment teaches him he should not attempt, such as, for instance, the application of forceps too early in delivery; vaginal or intrauerine manipulation; curettage; vaginal or intrauterine douches; and usually when there is a chill following such treatment, the worrying of the family will lead him to continue active treatment to the detriment of the patient and to his own reputation. I know that many times if he calls a consultant he will be supported in active interference. The laity has been taught and allowed to continue in the belief that retained secundines or portions of placenta or both are the cause of a complex symptomatology known as "blood poisoning," and whereas in an incomplete abortion, with placenta or membranes presenting at a dilated os, I advise careful removal by means of placental forceps or sponge stick, I feel that the active curettage that has been done in these cases is distinctly harmful. We may thus many times change a sapremia to an extensive pelvic lesion with its resulting toxemias, or perhaps to a bacteriemia. Thus it seems to me that it is high time that the laity were taught the meaning of an enthetic infection, and thus we should discourage wrongfully directed mechanical efforts to remove small pieces of placenta or membranes, which, if not discharged within a few days by Nature are discharged at a subsequent menstrual period. I use the term, enthetic, because autogenous is really a biological term, whereas enthetic means an infection which has been introduced from without. It may have been introduced at the time of the labor or abortion or at some remote period and brought into activity only by the conditions of which we are speaking.

In the list presented the cases were all under close personal observation in two hospitals. The

CHART OF 100 CASES OF POST PARTUM SEPSIS (DR. A. M. JUDD).

TIME IN HOSPITAL	DIAGNOSIS. DURATION OF PREGNANCY. DAYS POSTPARTUM OR POSTABORTIVE	TREATMENT BEFORE ADMISSION	TREATMENT IN HOSPITAL	REMARKS. MORBIDITY. CHANGE OF POSITION AND MANIPULATION. RESULT.	LABORATORY FINDINGS
5 days	P. A. bacteriemia 6 weeks	Induced	Conservative and vaccine	Initial rise 103° F. for five days. Fatal.	Streptococcus
15 days	P. A. metritis 4 months	Spontaneous	Conservative	Initial rise 104° F. 1 day, then normal 2 days. Vaginal examination 106° F. with chill, for 4 days 104° F., then normal for 3 days. Third rise 104.5 for 2 days after discontinuing Fowler, then normal. Recovery.	Negative
5 days	P. P. peritonitis pneumonia. 7 days P. P.	Spontaneous	Conservative	Initial rise 104° F. for 4 days, then 106.5° F. Fatal.	Negative
9 days	P. P. metritis 9 days P. P.	Spontaneous	Conservative	Initial rise 102° F. for 3 days, then normal. Recovery.	Negative
21 days	P. P. cellulitis 4 weeks	Spontaneous	Conservative	Initial rise 103° F. for 5 days, second rise 104.5° F., gradually normal after 9 days. Improved.	Negative
21 days	P. P. abscess of right gluteal reg. 12 days P. P.	Spontaneous	Incision and drainage	Initial rise 101° F. for 6 days, then 102° F. Operation, then temp. normal. Improved. Transferred for acute mania. Final recovery.	Negative
14 days	P. P. cellulitis 10 days P. P.	Spontaneous	Conservative	Initial rise 102° F. for 1 day; normal for 8 days; second rise 102° F. for 2 days. Then temp. normal. Recovery.	Negative
14 days	P. P. cellulitis 10 days P. P.	Forceps	Conservative and vaccine	Initial rise 105.5° F for 2 days, normal for 1 day; second rise 102.5° F. for 2 days, then temp. normal. Recovery.	Negative
56 days	P. A. bacteriemia perforated uterus 6 weeks	Induced	Conservative and vaccine	Initial rise 102° F. for 3 days, then normal. Recovery.	Streptococcus longus
14 days	P. A. metritis 6 weeks	Spontaneous	Conservative	Initial rise 103.5° F. for 2 days; second rise 102.5° F for 1 day; then temp. normal. Recovery.	Negative
14 days	P. A. cellulitis 3 months	Induced	Conservative	Initial rise 102° F. for 2 days, then normal. Recovery.	Negative
21 days	P. A. cellulitis 2 months	Spontaneous; Curette for bleeding	Conservative	Initial rise 105° F. for 4 days, normal for 1 day; second rise 106° F. for 2 days; then normal. Recovery.	Negative
12 days	P. A. cellulitis 8 weeks	Spontaneous	Conservative	Initial rise 102.6° F. for 2 days, then normal. She developed a very large exudate 1 month after discharge from hospital. Improved.	Colon bacillus in urine
40 days	P. P. pelvic abscess 8 weeks P. P.	Version	Incision above Pouparts	Initial rise 102° F. for 2 days; second rise 104° F. for 3 days; then normal for 3 days; third rise 102° F. for 1 day; fourth rise 104° F. Operation. Then normal. Recovery.	Negative
30 days	P. P. pelvic cellulitis 7 days P. P.	Spontaneous	Conservative	Initial rise 102.5° F. for 1 day, then normal. Recovery.	Negative
24 days	P. A. cellulitis	Induced	Conservative	Initial rise 104° F. for 2 days; temp. normal for 6 days; second rise 102.4° for 3 days, then normal. Recovery.	Negative
37 days	P. P. cellulitis 5 weeks P. P.	Forceps	Conservative	Initial rise 103° F.; then normal for 8 days; second rise with chill 103° F. after discontinuing Fowler. Next day chill, 103° F.; another chill, 103.2° F.; then temp. normal for 7 days; out of bed; then chill, 105° F. for 2 days; then normal. Improved.	Blood culture a number of times. Widal neg. Malaria neg.
1 day	P. A. cellulitis 8 weeks	?		Initial rise 101° F. Discharged against advice.	Negative
63 days	P. P. cellulitis 10 days P. P.	Spontaneous	Conservative	Initial rise 102° F. for 2 days; normal for 6 days; second rise 102° F. for 4 days; chill, 105.5° F.; then 103° F. for 11 days; normal for 3 days; third rise 103° F. for 2 days; normal for 20 days; fourth rise 103° F. for 2 days; then normal. Improved.	Negative
49 days	P. P. cellulitis 4 months P. P. 6 wks. pregnant on admission	Spontaneous	Laparot. left salpingo oophorectomy for tuboovar. abscess; mistake in diagnosis.	Initial rise 102° F. Operation; third day postoperative 102.4° F. for 3 days, then normal; 14 days post-operative, 102.5° F. for 6 days; then normal. Improved. Aborted 1 month after leaving hospital.	Gonococcus in fal. tube
35 days	P. P. cellulitis 6 days P. P.	Spontaneous	Conservative	Initial rise 104° F. for 1 day; normal for 19 days; second rise 103° F. for 3 days; then normal. Recovery.	Negative
28 days	P. A. cellulitis 6 weeks	?	Conservative	Initial rise 102° F for 2 days; normal for 3 days; second rise 103.4° F. for 3 days; normal for 3 days; third rise 103° F. for 2 days; normal. Recovery.	Negative
21 days	P. A. cellulitis 42 days	Induced	Conservative	Initial rise 104° F. for one day; chill, 105° F.; normal for 1 day; 102° F. for 6 days, then normal. Recovery.	Negative
35 days	P. P. cellulitis 5 days P. P.	Spontaneous	Conservative	Initial rise 103° F. for 2 days; gradually normal for 10 days; second rise 102° F. after discontinuing Fowler; normal in 2 days. Improved.	Negative
10 days	P. A. cellulitis 42 days bacteriemia	?	Conservative	Initial rise 103° F. followed by chill; 105° F. for 2 days; 104° F. for 1 day; chill, 105° F.; aborted, 100° F. next day; then normal. Improved.	Blood culture Staphylococcus
8 days	P. A. cellulitis	?	Conservative	Initial rise 103° F.; gradually normal in 3 days; then second rise 101° F. for 1 day; then normal. Improved.	
22 days	P. A. pelvic abscess 42 days	Induced	Postvaginal section	Initial rise 102° F.; gradually normal after 15 days. (Discharged against advice.) Improved.	Negative
24 days	P. A. abscess 42 days	?	Postvaginal section	Initial rise 102° F. for 1 day; normal for 2 days; second rise 103° F.; then 101° F. for 3 days; operation. Improved.	Negative
42 days	P. A. cellulitis 42 days	?	Conservative	Initial rise 103° F.; second day 105° F. with chill, ranging between 102° F. and 104° F. for 20 days. Then normal. Improved.	Negative
2 days	P. P. bacteriemia 12 days P. P.	Spontaneous	Conservative	Initial rise 105° F., then 103° F.; second rise, 100° F. Fatal	Streptococcus brevis
17 days	P. P. cellulitis 77 days	Forceps	Conservative	Initial rise 101° F. for 4 days; second rise 102.5° F. for 2 days, then normal. Recovery.	Negative
30 days	P. P. cellulitis 10 days P. P.	Spontaneous	Conservative	Initial rise 105° F. for 1 day; then 101° F.; normal for 3 days; second rise 102° F. for 3 days, then normal. Against advice. Recovery.	Negative
30 days	P. A. pelvic abscess	?	Postvaginal section	Initial rise 101° F.; operation; between 101° and 102° F. for 2 days, then normal. After laparotomy for mistaken diagnosis of tuboovarian abscess post-vaginal section done. Discharged against advice	Negative
10 days	P. A. pelvic cellulitis	?	Conservative	Initial rise 102° F. for 2 days, then normal. Admitted 4 weeks later to another hospital; operated on for pelvic abscess pointing above Poupart's ligament. Improved.	Negative

CHART OF 100 CASES OF POST PARTUM SEPSIS (DR. A. M. JUDD).

TIME IN HOSPITAL	DIAGNOSIS. DURATION OF PREGNANCY. DAYS POSTPARTUM OR POSTABORTIVE	TREATMENT BEFORE ADMISSION	TREATMENT IN HOSPITAL	REMARKS MORBIDITY. CHANGE OF POSITION AND MANIPULATION. RESULT.	LABORATORY FINDINGS
21 days	P. P. pelvic cellulitis. 8 days	Forceps	Conservative and vaccine	Initial rise 103° F. for 2 days; normal for 1 day; second rise 103° F. for 2 days; normal for 9 days; third rise 103.5° F. for 1 day, then normal. Recovery.	Negative
14 days	P. P. metritis 10 days	Forceps	Conservative and vaccine	Initial rise 105° F., chill; 102° F. for 8 days, then normal. Recovery.	Negative
21 days	P. P. exudate in abdominal wall 1 day	Spontaneous	Conservative	Initial rise 102° F. for 19 days; second rise 103° F. for 1 day; normal. Recovery.	Negative
28 days	P. A. cellulitis thrombophlebitis of popliteal 90 days	?	Conservative	Initial rise 106° F., chill, expelled fetus; 107° F., chill; expelled placenta; normal for 2 days; chill, 105° F. for 1 day, then normal. Recovery.	Negative
14 days	P. P. cellulitis 14 days	Spontaneous; packed for bleeding	Conservative	Initial rise 104° F. for 1 day, then normal. Recovery.	Negative
21 days	P. P. cellulitis 3 days	Spontaneous	Conservative and vaccine	Initial rise 104.5° F., gradually normal in 10 days; second rise 103.2° F. for 2 days, then normal Recovery.	Negative
10 days	P. P. metritis 3 days	Forceps	Conservative	Initial rise 101° F. for 5 days, then normal. Recovery.	Negative
28 days	P. A. cellulitis 42 days	?	Conservative	Initial rise 103.5° F. for 1 day; normal 5 days; second rise 103° F. for 3 days, then normal. Recovery.	Negative
21 days	P. P. cellulitis 14 days	Spontaneous	Conservative	Initial rise 103° F., chill; for 3 days normal; second rise 102° F., then normal. Recovery.	Negative
2 days	P. P. bacteriemia 3 days	Spontaneous	Conservative	Initial rise 106° F. for 2 days. Fatal.	Streptococcus
35 days	P. A. cellulitis	?	Conservative	Curetted at hospital for incomplete abortion. Initial rise 103° F.; second day normal; then 103° F.; for 3 days, normal; then 104° F.; normal 19 days. Against advice left hospital. Returned 1 month later; operated upon; postvaginal section; nothing found. Fatal 2 weeks after operation	Negative
21 days	Pelvic abscess P. A.	Spontaneous	Postvaginal section	Initial rise 101° F. 4 days; second rise 103° F.; operated upon. Recovery.	Negative
28 days	Pelvic abscess. P. A. rectovag. fistula to drain prev. op.	Spontaneous	Postvaginal section	Initial rise 100° F. for 8 days; operation; second rise 103° F. for 2 days, then normal. Improved.	Negative smears
42 days	P. A. retroperitoneal abscess 42 days	Spontaneous	Incision and drainage	Initial rise 102.5° F. for 9 days; operation; normal for 18 days; second rise 103° F.; gradually normal. Recovery.	Negative
28 days	P. P. cellulitis 28 days	Spontaneous	Conservative	Initial rise 103.5° F. for 5 days, then normal. Recovery.	Negative
21 days	P. A. cellulitis 42 days	Curettage	Conservative	Initial rise 102° F. for 7 days, then normal. Recovery.	Negative
16 days	P. P. cellulitis 3 days	Forceps	Conservative	Initial rise 103° F. for 9 days, then normal. Recovery.	Negative
21 days	P. A. pelvic abscess 42 days	?	Postvaginal section	Initial rise 104.2° F. for 2 days; operation 102° F.; then normal. Improved.	Positive Wassermann
28 days	P. A. pelvic abscess	?	Postvaginal section	Initial rise 101° F.; operation; then normal. Improved.	Negative
42 days	P. A. pelvic abscess	?	Postvaginal section	Initial rise 102.5° F. for 4 days; operation; 101° F for 5 days; then normal. Recovery.	Negative
16 days	P. A. pelvic abscess 42 days	Induced	Postvaginal section	Initial rise 101° for 1 day; operation. Recovery.	Negative
15 days	P. P. cellulitis 8 days	Abscess of vulva	Conservative	Abscess incised 8 days before labor. Initial rise 105° F.; between 103° and 105° F. for 6 days; normal for 2 days; second rise 101° F. for 3 days, then normal. Recovery.	Negative
28 days	P. A. pelvic abscess 42 days	Curettage for bleeding	Postvaginal section	Initial rise 101° F.; operation; 14 days normal; second rise 103° F. for 2 days, then normal. Recovery.	Colon bacilli; pus
6 days	P. P. pelvic cellulitis 4 days	Spontaneous	Conservative	Initial rise 101.5° F. for 2 days, then normal. Recovery.	Negative
16 days	P. A. pelvio peritonitis 56 days	Curettage for bleeding	Postvaginal section for diagnosis	Initial rise 102° F.; operation; 101° F. for 4 days, then normal. Recovery.	Negative
13 days	P. P. cellulitis 3 days	Spontaneous	Conservative	Initial rise 101.4° for 3 days, then normal. Recovery.	Negative
2 days	P. P. cellulitis desquamating erythema	Forceps	Conservative	Initial rise 101° F. for 3 days. Discharged against advice. Unimproved.	Negative
42 days	P. A. pelvic abscess	?	Postvaginal section	Initial rise 104.5° F. for 7 days; normal for 10 days; second rise 103° F.; operation; normal. Improved.	Negative
21 days	P. P. cellulitis 7 days	Spontaneous	Conservative	Initial rise 103.4° F.; gradually normal. Recovery.	Negative
42 days	P. A. pelvic abscess	Manipulation	Postvaginal section	Initial rise 101° F. for 13 days; operation; 102.5° F. for 9 days; 105.5° for 1 day, then normal. Recovery.	Negative
21 days	P. A. pelvic abscess	Curettage after abortion	Conservative	Initial rise 105° F.; gradually to normal in 4 days; second rise 102.5° F.; then normal. Recovery.	Smear neg.
21 days	P. A. pelvic abscess	?	Postvaginal section	Initial rise 101° F. for 2 days; operation; 102° F. for 2 days, then normal. Recovery.	Negative
14 days	P. P. cellulitis 10 days	Forceps	Conservative	Initial rise 103° F. for 6 days, then normal; second rise 102.5° F. for 3 days, then normal. Against advice. Improved.	Negative
21 days	P. A. pelvic abscess	Curettage for bleeding	Postvaginal section	Initial rise 104° F. for 2 days; second rise 105° F.; operation; normal in 7 days. Recovery.	Negative
9 days	P. P. metritis 9 days	Spontaneous	Conservative	Initial rise 100.5° F. for 2 days, then normal. Recovery.	Negative
25 days	P. P. cellulitis 14 days	Spontaneous	Conservative	Initial rise 102.8° F. for 2 days; normal 1 day; second rise 103° F.; gradually to normal. Recovery.	Negative
90 days	P. P. cellulitis 28 days	Spontaneous	Douches; vaccine	Initial rise 103° F.; for 30 days between 102°-103° F.; then gradually to normal. Improved.	Negative
14 days	P. P. cellulitis 14 days	Spontaneous	Conservative and douches	Initial rise 102° F. for 2 days; gradually to normal. Improved.	Negative
17 days	P. P. metritis 7 days	Forceps	Conservative and douches	Initial rise 102° F. for 3 days; then first douche, temperature being 99° F.; gradually to normal. Recovery.	Negative
21 days	P. P. cellulitis 11 days	Forceps	Conservative	Initial rise 101° F. for 2 days; then normal for 7 days; second rise 104° F.; out of bed caused rise from 99° to 104° F.; gradually to normal. Recovery.	Negative smears

CHART OF 100 CASES OF POST PARTUM SEPSIS (DR. A. M. JUDD).

TIME IN HOSPITAL	DIAGNOSIS. DURATION OF PREGNANCY. DAYS POSTPARTUM OR POSTABORTIVE	TREATMENT BEFORE ADMISSION	TREATMENT IN HOSPITAL	REMARKS. MORBIDITY. CHANGE OF POSITION AND MANIPULATION. RESULT.	LABORATORY FINDINGS
28 days	P. A. endometritis, metritis 42 days	Manipulation	Vaccine and douches	Initial rise 103° F.; temperature between 102° and 103° F. for 14 days; gradually to normal. Improved.	Negative
21 days	P. P. cellulitis 5 days	Spontaneous	Conservative	Initial rise 102° F. for 1 day; normal for 3 days; second rise 102° F. for 2 days; normal for 6 days; third rise 103° F. for 1 day; followed vaginal examination; gradually to normal. Recovery.	Negative
40 days	P. P. cellulitis 6 days P. P.	Forceps	Vaccine and conservative	Initial rise 104.5° F. for 2 days; normal for 10 days; second rise 103.5° F. after vaginal examination; gradually to normal for 8 days; third rise 104° F. after vaccine, for 4 days, then gradually to normal. Recovery.	Negative
42 days	P. P. cellulitis 4 days P. P.	Forceps	Conservative and vaccine	Initial rise 103° F. for 2 days; normal for 1 day; 103° F. for 9 days; gradually to normal; third rise 104° F.; gradually to normal. Recovery.	Negative
24 days	P. P. cellulitis 9 days P. P.	Forceps	Conservative and vaccine	Initial rise 101° F.; gradually to normal in 4 days. Recovery.	Negative

90 days	P. P. bacteremia; pyemia 2 days P. P.	Forceps	Incision of pyemic abscesses; vaccine	Initial rise 101° F. for 14 days; second rise 105° F. up and down for 14 days; between 101° and 102° F. for 28 days; between 102° and 104° F. Fatal.	Streptococcus brevis
35 days	P. A. cellulitis 42 days	Manipulation	Conservative	Initial rise 103° F. for 4 days, then normal. Improved.	Negative
14 days	P. P. cellulitis 6 days P. P.	Spontaneous	Vaccine	Initial rise 104° F., gradually normal in 4 days. Discharged against advice. Improved.	Negative
14 days	P. A. cellulitis 42 days	Curettage for bleeding	Conservative	Initial rise 101.5° F. for 2 days, then normal. Improved.	Negative
35 days	P. A. pelvic abscess 90 days	Manipulation	Postvaginal section	Initial rise 101° F. for 2 days; operation; no rise. Recovery.	Negative
14 days	P. P. cellulitis 7 days P. P.	Spontaneous	Conservative and vaccine	Initial rise 102° F. for 3 days, then normal. Improved.	Negative
35 days	P. P. cellulitis; phlebitis of arm. 6 days P. P.	Forceps	Conservative	Initial rise, chill, 102° F. for 3 days; gradually to normal. Recovery.	Negative
60 days	P. P. cellulitis; breast abscess 5 days P. P.	Spontaneous	Incision of breast; vaccine	Initial rise 104° F. for 3 days; normal for 2 days; 103° F. for 4 days; third rise, chill, 105° to 104° F. for 2 days; operation; normal for 5 days; fourth rise 104° F.; normal for 5 days; fifth rise 104 F. for 2 days; then gradually to normal. Improved.	Negative
21 days	P. A. pelvic abscess 60 days	?	Postvaginal section	Initial rise 104° F. for 1 day; normal for 2 days; operation; normal. Second operation 5 weeks after discharge; post-vaginal section. Improved.	Negative
21 days	P. A. pelvic abscess	?	Postvaginal section	Initial rise 102° F. for 2 days; operation; normal. Improved.	Negative
42 days	P. P. pelvic abscess 42 days	Spontaneous	Postvaginal section	Initial rise 104° F. for 3 days; normal for 19 days; second rise 101° F.; operation; normal. Recovery.	Negative
35 days	P. A. pelvic abscess	?	Postvaginal section	Initial rise 102.5° F. for 2 days; operation; normal. Recovery.	Negative
28 days	P. P. metritis 7 days	Spontaneous	Conservative	Initial rise 103° F. for 2 days; then normal. Recovery.	Negative
42 days	P. P. pelvic abscess 14 days	Spontaneous	Postvaginal section	Initial rise 104° F. for 4 days; normal for 5 days; second rise 102° F.; between 100° and 102° F. for 15 days; operation; then normal. Recovery.	Pus; Streptococcus
35 days	P. A. cellulitis 42 days	Manipulation	Conservative and vaccine	Initial rise 102.5° F. for 3 days; second rise 104° F. for 1 day; then normal for 8 days; third rise for 1 day; then normal. Improved.	Negative
35 days	P. P. cellulitis 14 days	Spontaneous	Conservative and vaccine	Initial rise 105° F. for 3 days; gradually to normal; second rise 103° F.; between 102° and 103° F. for 10 days; third rise 104.5° F. 1 day, after vaginal; then normal. Recovery.	Negative
21 days	P. P. peritonitis	Packed for placenta præv. In 14 days was septic	Conservative and vaccine	Initial rise 102.5° F. for 1 day; normal for 5 days; second rise 105° F.; up and down with chill for 8 days. Fatal. (Packed in hospital.)	Blood culture sterile
7 days	P. A. cellulitis 9 days	Curettage for bleeding	Conservative and vaccine	Initial rise 101° F. for 2 days; then normal. Recovery.	Negative
16 days	P. A. pelvic abscess 70 days	?	Postvaginal section	Initial rise 101.5° F. for 3 days; operation; normal for 7 days; second rise 102° F. for 2 days, then normal. Recovery.	Negative
21 days	P. A. pelvic abscess 42 days	Manipulation	Postvaginal section	Initial rise 102.5° F. for 2 days; second rise 104.5° F.; operation; then normal. Recovery.	Negative

aggregate stay was 2,518 days, a little more than twenty-five days for each case. Fifty-two were post partum, forty-eight postabortive. Of the fifty-two post partum cases thirty-four were said to be spontaneous deliveries, inasmuch as forceps were not used. We all know what is meant by the term, spontaneous, in a great many cases. The physician often uses his fingers coated with some lubricant for the purpose of dilating the vagina or cervix and still calls the case a spontaneous delivery. It may be spontaneous, but if the fingers were kept out of the vagina there would be a great deal less probability of infection. This is particularly true after the rupture of the membranes and in cases of so called dry labors. We are taught in the schools the importance of diagnosis of position and to follow the extent of dilatation of the cervix. If the position were always made out by means of abdominal palpation and auscultation, and the extent of dilatation of the cervix followed up by means of rectal examination, there would be much less post partum sepsis. Sixteen of the cases involved for-

ceps deliveries and two required version. When I speak of a spontaneous abortion in the list I simply call it so because the patient has so stated it. As some renowned obstetrician has remarked, and I think it is classical: "Any case of abortion which shows high temperature or a resulting cellulitis is not spontaneous; there has been some manipulation." While this statement is dogmatic, and one in practical work cannot agree with it in its entirety, it contains a great deal of truth. Considered as a truthful statement, it would be necessary to place a question mark after the whole list of so called spontaneous abortions.

As a working basis, we must have a classification and the most simple classification is: Toxemias. Under this are included the sapremias and also all cases with distinctly local lesions without bacteriemia. These local lesions varied from infected abrasions, tears of the mucous membranes of the vulva, vagina, and cervix, simple or extensive, into the broad ligaments, with resulting cellulitis or inflammatory conditions of the endometrium, myometrium, Fallopian tubes, ovaries, and peritoneum. Under the other heading I would place septicemia, and subdivide this into bacteriemias and pyemias. In the 100 patients ninety-three had toxemia. They varied from those who were only slightly ill to those who were extremely so. Six of the cases were bacteriemias, and one was a pyemia. I believe that a late rise in temperature, from six to ten days after delivery or abortion, which has been spontaneous or without manipulation, is due to the gonococcus.

There were seven deaths in the series. If the fatalities are criticized I answer that these patients were all sick enough to be sent to an institution. I think that will answer any criticism. Analyzing the deaths, five were post partum, and of these two showed negative blood cultures. One had peritonitis and the other died of a lobular, not a lobar, pneumonia. Doctor Stone, of Manhattan, holds that this is not a condition of pneumonia, but is due to infarcts in the lungs. Three of the post partum deaths had positive blood cultures, one showed bacteriemia and pyemia, and two bacteriemia only. One of the two postabortive cases showed a positive culture. We had one case of streptococcus bacteriemia that ended in recovery. We are discharging patients at the present time, who show cellulitis, as improved, not cured, as we find some of them are later showing up at other institutions with large exudates, some of them extending up to the crest of the ilium. The prognosis varies in the toxemias according to the severity of the symptoms and local lesions, and of course according to the patient's resistance. This is best shown by successive blood counts taken from day to day or every other day, depending upon variations of the leucocyte or differential, from which the attending physician can make a fair prognosis. The prognosis of bacteriemia is extremely bad and depends upon the resistance and the multiplication of the colonies.

TREATMENT.

It has been my pleasure to see many cases in consultation and to note the remarkable change for the better that takes place in a case when placed in proper hospital care, within twenty-four hours after admission. They are placed in better hygienic surroundings and taken away from the nervous importunities of the families. Given a case of postabortive or post partum infection, the first thing is to find the focus of infection. Of course general diseases should be excluded as well as the breasts before proceeding to a very careful abdominal and pelvic examination. The pelvic examination should be considered in the nature of an operative procedure, and should be handled in as aseptic or antiseptic manner as possible. Local lesions of the vulva and vagina are carefully noted, as are also all intrapelvic conditions. If placenta or membranes present at the external os, they are removed with the gloved finger or placental forceps, and nothing further in operative or manipulative line is done. In case of uncontrollable hemorrhage in postabortive cases, a carefully applied vaginal pack is to be used. This should be introduced with the patient in the Sims position and the gauze should be wet and wrung out in the antiseptic solution that is the attending surgeon's favorite. I advise against the use of vaginal douches, and when a case has become septic and all the conditions are as noted above, and it is sure that the uterus is to all practical purposes empty and contracted, the case should be let alone so far as instrumentation is concerned and treated conservatively, increasing the patient's resistance by all possible means, which practically includes concentrated nourishment and fresh air. In the Peter Brent Brigham Hospital, of Boston, which I had the pleasure of visiting a short time ago, every bed in the institution can be run out into the open air, which makes a model arrangement for this class of cases. There is a certain class of cases where the body of the uterus is flexed upon the cervix with a retention of fluid blood. This uterus may be emptied at the primary examination by simply passing the finger into the cervix and allowing the blood to drain off, with a resulting drop of the temperature. I approve of the Fowler position, especially in cases where the lesion has extended to the peritoneum. As the cases proceed, many of them result in abscess formation which may point in the posterior fornix, about Poupart's ligament, or as occurred in one of my cases, in the guteal region. The abscess should be treated like an abscess anywhere else in the body, by incision and drainage. In posterior vaginal section as I practise, the cavity is not washed out, but is simply drained and tightly packed with iodoform gauze, which is allowed to remain in place for at least twelve days. We have thereby an opening at the vault, which, on removal of the gauze, will not completely close down, until the cavity above has had time to become obliterated. Too early removal of the gauze results in the closure of the opening with the necessity for enlarging it subsequently.

As to the indications for vaccine, I have no faith in them, except in one condition. In an old pelvic exudate with pus, where there has been a section or incision above Poupart's ligament, where there is still a discharging sinus after weeks of drainage, an autogenous vaccine may be of benefit. But as for the use of vaccines early in active cases, I do not approve of them. Some of my early cases

had vaccines used because my associate was a great believer in them at that time.

The daily use of catharsis is bad. A patient who is on a fluid or soft diet does not require a movement of the bowels every day, and when necessary, in the majority of cases, we may use a simple soapsuds enema, or at times a dose of castor oil, or some mild laxative. The use of the Gellhorn baker, which is a series of electric light bulbs in a frame, is a valuable adjunct in the chronic cases with large exudates without fever. Iron and arsenic in old cases are of value.

The main value of this paper, I believe, is in the list of cases presented for study, and the opportunity of bringing once more to the attention of the profession the value of conservatism in the treatment of these two important conditions. I take advantage of this opportunity to thank my assistant, Dr. Harry Unger, for his aid in working up the histories.

375 Grand Avenue, Brooklyn.

THE SURGICAL STAFF CONFERENCE.*

By Frank E. Adair, M. D.,
New York.

It is requisite that every surgical service of a hospital have periodically a systematic review of its full activities; only then is it possible to obtain an exact knowledge of its strength and its weakness, its successes and its failures. It is in order to obtain such a complete comprehension of all its activities that the weekly Staff Conferences of the second surgical division of the New York Hospital are held. These conferences are attended by the entire attending and house staff. They include:

I. A review and discussion of the work of the past week.
II. A report from the standing staff committees:
1. Outpatient department.
2. Clinical clerks.
3. Operating room technic and efficiency.
4. Supervision of charts and clinical records.
5. Anteoperative and postoperative treatments.
III. A brief report on any subject assigned by the chief to a staff member; or a review of the literature having a bearing on some unusual case in the hospital.

Such a program is not only very instructive to all, but shows with equal clearness results which are satisfactory and those which are unsatisfactory. By taking advantage of the resulting information, the staff energy and vigor can be efficiently and profitably directed. Such careful scrutiny of the work as the conference affords, reacts in increased enthusiasm and caution, and produces happier results. So great have been the stimulation, pleasure, and profit derived therefrom, that it has seemed desirable to submit to the profession, the details of the system followed at these conferences. Review of the work of the past week includes a study of:

I. Infections.
II. Deaths.
III. Postoperative complications—pneumonias, hematomas, etc.
IV. Unsatisfactory results in cases traced by the follow-up system (1).

At the conference every case of operative or postoperative infection is studied with the idea of tracing the infection to its source. In any case of diagnostic error, a retrospective study is made to determine the reason for the error—whether it is due to:

1. Lack of consideration of the patient's history.
2. Haste in the physical examination.
3. Lack of laboratory data.
4. Other causes.

Thus where diagnostic errors have been made, or where infection, death, or any other unsatisfactory phenomenon has followed operation, the operator explains in detail at the conference his viewpoint and reasoning on that particular case—or his excuse, as it may be—and he has thereby an opportunity to defend himself.

Our attending surgeon, Doctor Pool, has made it a rule that free discussion at the conferences shall be the privilege of every member of the staff, including attending surgeons and interns. This point cannot be overemphasized, for it is herein that part of the success of such a conference lies; if this was not true, many interesting and original ideas would be stifled, and enthusiasm would be diminished.

It is the duty of the junior surgeon to compile the data for the résumé, and to arrange it in forms convenient for presentation. In compiling these details (see Form IV), he obtains the operative list of the week from the book of operations kept in the operating room. Infections, deaths, postoperative pneumonias, or hematomas are described on the patient's chart. Anteoperative and postoperative diagnoses are found recorded on the anesthetic page in the patient's chart. The data on the cases which are being followed up are taken from the file cards of those patients who were notified to report on the previous "Return Day."

In reviewing the cases of our follow up system, time is not consumed on cases with satisfactory results, but study is made only of cases whose results are not satisfactory.

The forms below are compiled with the idea of giving an example of some of the items studied at the conference.

The initial letters placed in the margin beside the particular case report in Form III below, designate the classification of the end results. The system followed is that published by Codman (2), of Boston. Examples: E-s means error in skill; E-j, error in judgment; E-c, error in care or equipment; E-d, error in diagnosis; P-d, patient's disease, such as cancer, and C, a surgical calamity, such as embolism.

After full discussion of the cases, the attending surgeon places appropriate initials beside the case report.

By following this method, Codman maintains it is possible "to ascertain the results of the treatment given and to analyze the causes of failure in cases in which the treatment has been successful," and thereby "prevent similar failures in the future."

The following detail and explanation gives a few of the chief reasons for the adoption of such a system.

I. The weekly conference brings to the attend-

*Read before the Brooklyn Surgical Society, May 4, 1916.

ing surgeon an accurate conception of the entire activity of his service. The strong and weak points of individual members of his staff are prominently projected. The surgical judgment, diagnostic skill, and technic of each operator, with the end result of his cases, are manifest.

II. The mere fact that cases which have other than a satisfactory end result are to be reviewed and critically discussed, is sufficient to induce increased caution and thought in, *a*, the anteoperative diagnosis; *b*, the operation; *c*, the postoperative treatment. Indeed the entire staff becomes more open eyed and vigilant as a result of the friendly criticisms brought out in the conference. Interest is greatly augmented and stimulated.

III. In any case of unusual interest, much is to be learned at the conference by reviewing systematically, *a*, the history; *b*, the physical examination; *c*, the laboratory findings—chemical, bacteriological, and pathological; *d*, the x ray plates; *e*, the operative note—for the operator's rationale; *f*, the subsequent course of the patient in the hospital. A full discussion in these particular cases is extremely valuable to each member of the staff—especially to the younger surgeons.

IV. In certain operative crises, the problem of the wisest procedure confronts even surgeons of wide experience. At the conference a review and discussion of such crises are most profitable to all.

V. The study of our infections follows fairly closely the scheme of Brewer (3). The "questionable cases" offer a most interesting class for study; if the bacteriological reports are consistently coupled and compared with the clinical records, the problem of drainage in borderline cases of appendicitis, peritonitis, etc., will be more easily solved; and some criterion can be established for procedure in these puzzling cases.

Beside problems of infection common to surgery in general, each hospital has its own particular problems of operating room and ward infections; and herein lies opportunity for work in order to eliminate some of the local contributing factors.

VI. Postoperative pneumonias, like infections, have causes which are common to every clinic, but each hospital may have some contributing factors peculiar to itself; these form a subject for valuable work.

The attending surgeon can assign as an *Arbeit* to a member of his staff the influence of certain factors in relation to postoperative pneumonia, e. g., the study of, *a*, the bacteriology of postoperative pneumonia (4); *b*, the different types of anesthetic apparatus used; *c*, the various anesthetic agents used; *d*, the quantity used; *e*, the clothing of the patient at the time of operation; *f*, the months when postoperative pneumonias are most prevalent, together with the record of temperatures, drafts, etc., in operating room and recovery rooms during these months.

By thus studying carefully a considerable number of cases, valuable conclusions may be drawn; and some of the causes contributory to postoperative pneumonia may be eliminated.

VII. The study and discussion of all the factors involved in the various cases of postoperative hernia and hematoma, together with some well directed experimental work, ought to result in valuable remedial conclusions.

FORM I.

Résumé of Week, September 1 to 7, 1915, inclusive.

Cases operated in 34

I. *Infection Record.*

Clean cases (anteoperative):

Asepsis maintained	21
Asepsis lost	1
	22
Questionable cases (anteoperative)	2
Septic cases (anteoperative)	10
	34

Remarks—Clean cases (anteoperative):

Pt. K. Johnson, Ward O. Operator, Dr. X. Ventral hernia. Asepsis lost.

Questionable cases (anteoperative):

Pt. H. Richard, Ward E. Operator, Dr. X. Mesenteric thrombosis. Bacteriological report of culture taken at operation, "B. coli." Wound not drained. Uneventful recovery.

Pt. S. Smith, Ward O. Operator, Dr. Z. Chronic salpingitis. Bacteriological report of culture taken at operation, "Sterile." Wound not drained. Uneventful recovery.

II. *Deaths* (2).

Pt. U. G. Herz, Ward K. Operator, Dr. X. Diffuse peritonitis and postoperative pneumonia.

Pt. R. E. Reilly, Ward K. Operator, Dr. Y. Septic endocarditis with numerous emboli. Patient was operated upon for mesenteric embolus; recovered from surgical condition uneventfully. Two weeks later, patient died from a cerebral embolus.

III. *Postoperative hematomas* (1).

Pt. A. Smith, Ward K. Operator, Dr. X. Cystic goitre. A small sized rubber tube placed in middle of the incision for drainage. Hematoma formed at upper pole of right lobe; drained through primary incision.

IV. *Postoperative pneumonias* (2).

Pt. S. Brown, Ward E. Operator, Dr. Z. Resection right knee for joint tuberculosis. Anesthetist Dr. A. Gas for induction; ether oz. 5. Time, 40 minutes. Patient had a rhinitis at the time of operation. Right lower lobe involved. Cleared up within four days. Uneventful recovery from pneumonia.

Pt. U. G. Herz. (See under Deaths above.)

FORM II.

Diagnostic Errors of Week September 1 to 7, Inclusive.

Pt. W. S., Ward K. Operator, Dr. X. Anteoperative diagnosis, Acute appendicitis. Postoperative diagnosis, Mesenteric thrombosis.

FORM IV.

Date of Op.	Pt.'s Name	Operator	Ward	Anteoperative Diagnosis	Postoperative Diagnosis	Wound Anteoperative: Aseptic	Questionable	Septic	Asepsis Lost
Sept. 1, 1915	S. Schwartz	Dr. X.	Q	Fibromyoma uteri	Same	+	o	o	o
Sept. 1, 1915	E. Jones	Dr. X.	K	Chronic appendicitis	Same	+	o	o	o
Sept. 1, 1915	U. Herz	Dr. X.	K	General peritonitis	Same	o	o	+	o
Sept. 1, 1915	K. Johnson	Dr. X.	O	Ventral hernia	Same	+	o	o	+
Sept. 1, 1915	H. Richard	Dr. X.	E	Acute appendicitis	Mesenteric thrombosis	o	+	o	o
Sept. 2, 1915	D. Bean	Dr. Y.	E	Bone cyst	Same	+	o	o	o
Sept. 2, 1915	J. Shappiro	Dr. Y.	O	Diverticulitis	Adhesions about colon	+	o	o	o

Pt. I. L., Ward O. Operator, Dr. Y. Anteoperative diagnosis, Diverticulitis. Postoperative diagnosis, Adhesions about colon."

Pt. P. D., Ward E. Operator, Dr. Z. Anteoperative diagnosis, Hydrosalpinx. Postoperative diagnosis, Ovarian cyst.

FORM III.

Follow Up System—Return Day.
Sunday, September 5, 1915.

Cases to report 60

	Number.	Percentage.
Cases reporting in person	50	83
Cases reporting by mail	4	7
Total cases reporting	54	90
Cases not reporting	6	10

Results in the fifty-four cases reported:

Good	48
Fair	2
Poor	3
Dead	1

Analysis of "Fair, Poor, and Dead" Cases:

Fair: Pt. R. F. (E-j.) Operator, Dr. Z. Tuberculous cervical adenitis. Incomplete dissection. At present there is enlargement of and discomfort in the nodes not removed at operation.

Pt. A. C. (P-d.) Operator, Dr. X. Adhesions about gallbladder. At present indefinite discomfort in right upper quadrant. Constipation.

Poor: Pt. E. S. (E-s.) Operator, Dr. X. Nephrolithiasis and perirenal abscess. Patient has a persistent sinus.

Pt. B. D. (E-d.) Operator, Dr. Y. Chronic appendicitis. Patient has a persistence of the indefinite abdominal discomfort.

Pt. C. H. (P-d.) Operator, Dr. Z. Tuberculous peritonitis. General health is very poor.

Dead: Pt. L. U. (P-d.) Operator, Dr. Y. Carcinoma of gallbladder. Letter from patient's daughter states that patient died eight months after the operation.

Postoperative hernia (1).

Pt. H. F. Operator, Dr. Z. Acute appendicitis with drainage of appendix abscess.

Form IV is that used by the junior house surgeon for compiling the data. It is the only one of the four forms herewith shown which is not presented at the conference; but the information contained therein, is used as the basis of Forms I and II.

TESTICULAR SYPHILIS,

With Particular Reference to Gumma,

By M. Zigler, M. D.,
New York,
Instructor in Genitourinary and Venereal Diseases, Post-Graduate Medical School and Hospital; Chief of Genitourinary Clinic, Lebanon Hospital.

Before going into the detailed history of these cases of testicular syphilis, it would not be amiss to quote from Symmers's paper entitled, Anatomic Lesions in Late Acquired Syphilis: a Study of 314 Cases Based on the Analysis of 4,880 Necropsies at Bellevue Hospital, published in the *Journal A. M. A.* for May 6, 1916: "There is a syphilitic lesion of the testicle characterized by slowly progressive hyperplastic changes in the connective tissue eventuating in complete or partial sclerosis of the organ, the so called chronic interstitial orchitis. . . . Among 171 male subjects of late acquired syphilis in the Bellevue Hospital series, chronic interstitial orchitis was found sixty-seven times, or in thirty-nine per cent. . . . In connection with the general subject of testicular syphilis it is worthy of emphasis that in not one of the 314 cases of fatal acquired syphilis did we encounter gumma of the testicle proper."

Since almost forty per cent. of adult syphilitic males eventually acquire syphilis of the testicle, it behooves us to be more on the watch for chronic interstitial orchitis. This percentage of occurrence of syphilitic testicle is certainly much higher than I had been led to suppose by both private and hospital experience. Since such is the case, all patients with testicular involvement, where the diagnosis does not readily fall into either the gonorrheal or tuberculous class, should receive both the benefit of a Wassermann and a thorough antisyphilitic therapeutic test. If this is done, syphilis of the testicle will respond to treatment as elsewhere in the body. Thereby the patient will be spared the possibility of further serious damage to his testicles; possibly even spared the loss of one or both testicles, as in the cases I am about to report.

Mistakes in the diagnosis of syphilis are so many that we must consider the possibility of syphilis in almost every patient who comes to us, no matter what the complaint. I shall quote from my article entitled Pitfalls and Mistakes in the Diagnosis and Treatment of Syphilis (*New York State Journal of Medicine*, January, 1915): "The object of this paper is to bring out, first, the fact that a certain number of patients never knew that they had been infected with syphilis; secondly, that there is a larger group who really forget that they had been infected; thirdly, another class still greater in number than the preceding who, although they knew that they had been infected, are not conscious of the fact that their past syphilis has any relation to present manifestations; and lastly, we come to the most important class of patients, who 'try to live down' their syphilis and wilfully deceive their physician as to their past. . . . For these various reasons and because some of the manifestations of syphilis are at times so vague and uncharacteristic, if I may use this term, mistakes in the diagnosis and treatment of syphilis are very much more frequent than we suppose."

The following are the reports of three cases of testicular syphilis, the first two being gummata. Because of the great rarity of testicular gumma as emphasized in Doctor Symmers's paper and because one of the patients was absolutely unsexed and the other partially so, these cases are reported.

Case I. S. M., aged twenty years, single, stage hand. Personal and family history: Neither he nor any member of his family ever had tuberculosis. Past history: Had never had gonorrhea. Denied ever having had intercourse with the opposite sex. About four and one half years ago had rectal intercourse with another young man. Some time thereafter, interval uncertain, he noticed a small sore on the head of his penis. Said that it was not accompanied

by pain. As far as he knew, there was neither a generalized eruption after the appearance of this lesion nor were there other secondary symptoms. About four years ago, and about six months after the appearance of a lesion on his penis, the right testicle suddenly became swollen to about the size of a baseball. During the first two months this was not accompanied by pain; thereafter at times it was slightful painful. Two months later the left testicle gradually became swollen. Then for the first time he consulted a physician, who made the diagnosis of tuberculosis of the testicles. Within six months of the onset of his testicular condition, each testicle had developed to the size of an orange. At this time both testicles were operated upon. He was unable to state the nature of the operation.

After the operation his testicular condition was worse. A number of sinuses broke through each testicle. Tuberculin was then tried. He received one injection weekly for about twenty weeks. He also took creosote and cod-liver oil internally, without benefit. He was then sent away to the country. This also failed to cause any improvement in his condition. During this entire period, in addition to symptoms referable to his testicle, he also suffered with pain in the back and in both knees. He was very weak generally and suffered from restlessness and insomnia at night.

Present history dated back to May, 1914, which was about two years after the onset of his trouble. It was then that I saw him for the first time, at the clinic. His chief complaint was enlargement and swelling of both testicles, persisting for two years. Examination showed that both testicles were double their normal size, with a number of sinuses draining out of each. Careful palpation of the right testicle disclosed the fact that the epididymis and the body of the testicle were matted together into one soft, boggy, fluctuating, degenerated mass. The same was true of the left testicle. The patient looked feverish and septic.

This patient was admitted to the hospital May 6, 1914, and operated upon. Both testicles were taken out very much degenerated. The laboratory report, some days later, was gumma of both testicles. A Wassermann of the blood was then taken and found to be plus four. From that date, May 6, 1914, to July, 1916, he has received about forty injections of mercury salicylate, and potassium iodide internally in large doses. During this period he has gained twenty pounds. He no longer suffers with insomnia and feels absolutely well in every way.

This case is reported, first, to show how closely syphilis of the testicle may simulate tuberculosis of that organ and how dire the results may be, if testicular syphilis is allowed to go without specific medication. Secondly, here is a young man but twenty years old who is already unsexed. What the final outcome, because of the lack of testicular internal secretion will be on his general economy, is still to be seen. That some profound changes will take place from lack of the internal testicular secretion, is probable, because within nineteen days of the operation, both breasts became enlarged to the size of a silver dollar. In addition, they were tender and painful. At the end of two months the breasts were still enlarged to the size of a silver quarter. Is this a compensatory process of the mammæ, to make up for the loss of internal secretions of the testicle? The patient is absolutely sure that he never had swelling of the breasts before. Thirdly, the case is reported because of the great rarity of gumma of the testicle, especially bilateral gumma.

Case II. Mr. A. W., clinic patient, aged twenty-eight years, married. Family history: Married four years. His wife had one child, who died after two months, cause unknown. Neither he nor any member of his family ever had tuberculosis. Venereal history: Had gonorrhea eight years ago. Denied ever having had a chancre or other manifestation of syphilis. Past history: October, 1915, was operated upon for a double inguinal hernia. Said that immediately after the operation the left testicle became enlarged to the size of a pear. Two weeks later the right testicle became involved. Two months after the onset of his left testicular condition, it broke down into abscess formation, so that a left orchidectomy was performed on December 8, 1915. Ever since the onset of his trouble, the right testicle has remained swollen and hard. Present history: This patient came under my observation at the Post-Graduate Hospital, for the first time in May, 1916, about ten weeks ago. At that time complained of enlargement of his right testicle, which had remained swollen during the past seven months. In addition had pains all over body and felt generally weak. Suffered so severely with insomnia that he rose in the morning completely exhausted. Examination at the first visit showed that the right testicle was about twice its normal size, thickened, and hardened. The entire testicle was involved, both epididymis, and the body of the testicle. The left testicle was absent. A Wassermann of the blood was taken and found to be plus four.

For the past two months he had received potassium iodide, grains thirty, three times a day, and mercury internally, with marked improvement in the local and general symptoms. The testicle had gone down about one half, so that it was now almost its normal size, but was still quite hard. This marked diminution in size in such a short period of treatment, in spite of the fact that all other methods of treatment for seven months failed to improve the condition, undoubtedly spoke for syphilis of the testicle, especially when the strongly positive Wassermann was considered. In fact, the patient said that during the seven months preceding the course of specific treatment, his right and only testicle was constantly becoming heavier and larger. The marked restlessness at night also spoke for syphilis. Unfortunately I could not obtain the extirpated testicle.

In this case apparently marked manifestations of syphilis did not appear until the patient was operated upon for hernia. Syphilis not infrequently acts in this manner. That is, syphilis does not seriously affect or threaten an organ or a person until organ or person is either locally or generally devitalized by some other condition, disease or trauma. In this case very likely the handling of the cord during the hernia operation was enough to irritate the cord or possibly carry infection down the same. After the ordinary infection had started the trouble, Spirochæta pallida very promptly attacked the site of lowered resistance. It is just for this reason, in this type of cases, that the diagnosis of syphilis is at times so difficult. Syphilis at times engrafts itself so insidiously into or upon another infection that lues is not thought of by the surgeon. The only diagnosis in the mind of the attendant is the primary condition. For the reasons named above this patient was obliged to lose one of his testicles. If syphilis had been thought of, there is no doubt that both testicles could have been saved.

The third patient to be reported undoubtedly had a syphilitic interstitial epididymoorchitis, accompanied by hydrocele. Symmers's article speaks of this condition as being frequent, and says that gummata of the testicle are rare. To my mind it is quite possible for a patient to begin with an interstitial syphilitic orchitis of a mild type which, if untreated, may change to the more malignant form of syphilis, namely, gumma. Of course this is only a possibility. We all know that syphilis frequently has done just that. Mild primary and secondary syphilis may terminate in severe tertiary syphilis. We may start

with mild secondaries, allow them to go untreated, and see develop most malignant tertiaries.

CASE III. H. U., man, twenty-three years old. Past history: Ten months ago, acquired an initial lesion at the base of the index finger of his right hand. This was the result of a fight, during which he had punched another man in the mouth. Eight months ago secondaries developed, manifested by mucous patches on the tonsils and moist papules on the penis. The blood showed a positive Wassermann reaction. Received one intravenous injection of salvarsan and a number of mercury salicylate injections intramuscularly. Subsequently took mercurials by mouth, after which symptoms disappeared and the patient discontinued treatment for several months. Present history: April 4, 1915, came to my office with the history that eighteen days ago severe pain in the left testicle had suddenly developed, followed by a sudden enlargement. After one week, went to a doctor, who diagnosed his condition as an acute hydrocele. The sac was successfully tapped several times, but refilled promptly. His physician then advised him to go to the hospital for a radical hydrocele operation. After remaining in the hospital for twenty-four hours and not being operated upon promptly, he became discouraged and left the institution without operation. Examination on April 4, 1915, showed that the left testicle was swollen to about twice its normal size. Palpation showed that he had a hydrocele, accompanied by an epididymitis. Because of the sudden onset of hydrocele, in a patient known to be syphilitic prior to this present involvement, I made the diagnosis of a syphilitic testicle.

The hydrocele sac was tapped at once and about one ounce of clear fluid was obtained. In addition he received an injection of mercury salicylate, potassium iodide, grams fifteen, three times a day, with an increase of one grain each dose. I assured him that the entire process would clear up without operation, which it promptly did.

In Cases I and II, unfortunately, early diagnosis was not made, so that the former patient lost both testicles and the latter but one. The second patient, in addition to losing one testicle, sustained considerable damage to the remaining one; the diagnosis, however, was made soon enough to save the remaining one from utter destruction. The third case, while not so malignant, almost came to operation. The diagnosis having been made earlier, the patient was possibly saved from a fate similar to patients one and two. Of course, all syphilitic testicles do not go on to gumma formation, but even the rare possibility should be emphasized, so that early diagnosis, followed by prompt and intensive treatment, may be instituted. Another important point is that neither of the first two patients knew that they had been infected with syphilis. In fact, the first patient repeatedly denied either intercourse or a lesion. It was only after repeated questioning that he finally admitted homosexual connection and the subsequent initial sore.

In conclusion I will again quote from my article on Pitfalls in Diagnosis: "The foregoing series of mistakes in the diagnosis and treatment of syphilis are pointed out, not in a spirit of criticism, but rather to show how frequently such errors are made, and as a warning that we should be on our guard against the many pitfalls of this hidden and almost mysterious disease which makes its appearance in such divers ways, and may simulate some of the characteristic symptoms of a large number of other conditions and diseases."

40 EAST FORTY-FIRST STREET.

A FEMALE MEDICAL CLINIC.

A Report from Mount Sinai Hospital Dispensary.

BY MORRIS H. KAHN, M. D.,
New York,
Attending Physician, Clinic in Internal Medicine, Mount Sinai Hospital Dispensary; Assistant in the Department for the Study of Heart Disease, Mount Sinai Hospital.

The following is a report and an analysis of the work done in one of the medical clinics of the Mount Sinai Hospital Dispensary during the two years ending May 1, 1916. The objects in making this study were the following:

1. To ascertain the proportion of the various diseases as they appear for treatment in the clinic.
2. To analyze some of the problems confronted, viewed from the standpoint of the clinic physician.
3. To advocate the establishment of a special clinic for the study and treatment of cases of heart disease.
4. To suggest a system which will require the head of each clinic to make an annual or biennial report of the work done.

I. CLASSIFICATION OF CASES.

In dispensary practice, the complaints of any one patient may be manifold and most diverse; there may be many factors contributing to the patient's illness. On this account it is at times difficult to establish a diagnosis until we have discovered the different influences at work. We must remember that the problems confronting us are social as well as medical. Beside the ills that human flesh is heir to, not a few of the patients suffer from ills of the human mind and the inhuman purse.

It is therefore important in each case to correlate the symptoms with the physical signs. In cases of poverty or domestic strife, or in cases of headache and nervousness of uncertain origin, we should follow the principle that the physical or organic condition takes precedence of the functional complaint, and our diagnosis should be made accordingly.

During the two years ending May 1, 1916, there were admitted to our female medical clinic 1,702 new patients; these we classified in a table, according to their predominating ailment:

CLASSIFICATION OF DISEASES.	NUMBER.	PROPORTION.
General Diseases.		
Rheumatism, acute articular	2	
Rheumatism, subacute articular	19	
Rheumatism, chronic periarticular	3	
Arthritis deformans	6	
Torticollis and rheumatic myositis	7	
Diabetes mellitus	30	1.7 per cent.
Diabetes insipidus	1	
Exophthalmic goitre	17	1 per cent.
Nontoxic goitre	6	
Obesity	11	
Systemic syphilis	5	
Starvation from lack of food	4	
Fatigue from overwork	3	
Metastatic carcinoma	2	
Mesenteric neoplasm	1	
Acute abscess of rib	1	
Acromegaly	1	
Dercum's disease	1	
Cervical rib	1	
Senility	3	
Acute Infectious Diseases.		
Acute follicular tonsillitis	8	
Typhoid fever	1	
Typhus fever	1	
Diseases of the Alimentary System.		
Constipation	545	32 per cent.
Hyperacidity	38	
Anacidity	7	
Gastric ulcer	8	
Gastric neurosis	5	

CLASSIFICATION OF DISEASES.	NUMBER.	PROPORTION.
Duodenal ulcer	1	
Carcinoma of the esophagus	6	
Pyorrhœa alveolaris	3	
Acute colitis	7	
Hemorrhoids	1	
Mucous colitis	1	
Chronic enteritis	2	
Abdominal tuberculosis	1	
Visceroptosis	4	
Intestinal tæniasis	6	
Appendicitis, acute	6	
Appendicitis, subacute	22	
Appendicitis, chronic	17	
Postoperative adhesions	15	
Diseases of the Liver and Gallbladder.		
Cholelithiasis	47	2.7 per cent.
Cholecystitis	3	
Catarrhal jaundice	2	
Hepatoptosis	1	
Diseases of the Respiratory System.		
Acute laryngitis	16	0.6 per cent.
Acute bronchitis	195	11.4 per cent.
Chronic conditions of nose and throat	11	
Emphysema and chronic bronchitis	39	
Bronchial asthma	25	1.4 per cent.
Acute pleuritis—fibrous	6	
Acute pleuritis—with effusion	2	
Pulmonary tuberculosis	39	2.2 per cent.
Suspected pulmonary tuberculosis, referred for examination	80	4.7 per cent.
Mediastinal tumor	1	
Pulmonary tuberculosis with pregnancy	3	.17 per cent.
Diseases of the Heart and Bloodvessels.		
Chronic endocarditis	45	2.6 per cent.
Chronic myocarditis	1	
Auricular fibrillation	9	
Paroxysmal tachycardia	3	
Sinus arrhythmia	1	
Ventricular extrasystoles	1	
Chronic endocarditis with pregnancy	2	
Angina pectoris	2	
Pseudoangina pectoris	1	
Aneurysm of the aorta	1	
Varicose veins of legs	5	
Diseases of the Blood and Lymph Glands.		
Secondary anemias	12	
Chlorosis	1	
Primary pernicious anemia	1	
Hodgkin's disease	3	
Polycythemia with splenomegaly	1	
Polycythemia with emphysema	1	
Acute lymphatic leucemia	1	
Tuberculous cervical adenitis	1	
Diseases of the Urinary System.		
Acute parenchymatous nephritis	3	
Chronic parenchymatous nephritis	18	
Chronic interstitial nephritis	4	
Nephrolithiasis and ureteral calculus	12	
Nephroptosis	16	
Acute pyelitis	1	
Enuresis—nocturnal	1	
Chronic cystitis	1	
Tuberculous cystitis	1	
Malingering hematuria—beet coloring matter.	1	
Gynecological Diseases.		
Pregnancy—uncomplicated	49	2.8 per cent.
Amenorrhea	1	
Fibroid uterus	7	
Metrorrhagia after abortion	5	
Retroversion	3	
Chronic endometritis	2	
Sterility	1	
Fissured nipples in lactating breasts	1	
Ovarian cyst	4	
Diseased annexa	2	
Diseases of the Nervous System.		
Headache	60	3.5 per cent.
Nervousness	60	3.5 per cent.
Nervous symptoms of menopause	7	
Hysteria	2	
Grand mal epilepsy	1	
Chorea minor	3	
Tabes dorsalis	1	
Sciatica	3	
Cerebellar tumor	1	
Functional tremor	1	
Diseases of Special Senses.		
Chronic catarrhal otitis media	3	
Skin Diseases.		
Autotoxic urticaria	7	
Psoriasis	1	
Pityriasis versicolor	2	
Prurigo	1	
Pediculosis capitis of 237 examined, positive	172	75 per cent.
Ichthyosis	1	
Acne facialis	1	
Poisoning.		
Cocaine	1	
Sodium chloride edema of legs	1	
Orthopedic Conditions.		
Pes planus	2	
Surgical Cases.		
Abdominal hernia—inguinal, femoral, umbilical, ventral	14	
Minor injuries—none serious	11	

II. ANALYSIS OF SOME OF THE CLINICAL PROBLEMS.

Most of the items in our classification require no comment. We shall discuss only very briefly some of the more important problems of a dispensary clinic from their medicosociological aspects.

Functional derangements and dispensary treatment.—From the table it is seen that the most frequent complaint for which patients seek dispensary care in a medical clinic is constipation. Of the 1,702 new patients seen during the two years, there were 545 with functional constipation, or thirty-two per cent., practically one third of the total number treated.

In making this diagnosis it was our particular desire to exclude from this category all cases which depended on an organic cause, or in which any other physical condition existed of equal importance to the constipation. The 545 cases include only the functional disorder, as diagnosed after an extended period of observation.

In most of them the ultimate cause of the malady was an irregular mode of living. The few minutes of teaching in a clinic could do little to change this. The prescription gave direct, but usually only temporary relief. These patients visited us weekly as they would a drug store, to obtain the prescription for their favorite laxative. Many even sent a messenger for the medicine.

Are these proper patients for prolonged dispensary care after the diagnosis has been definitely established? It appears to us that if a sufficient quantity of medicine is given to last from four to six weeks or more, these patients may be kept under observation in the clinic indefinitely. If the medicine, however, is inexpensive and obtainable in a drug store, such as the vegetable cathartics, these patients can no longer be considered proper dispensary charges, and should be directed to obtain medicine in the dispensary or drug store without repeated consultations, unless new developments in their condition take place.

This may seem a radical suggestion, but it would reduce to a small fraction the innumerable caravan of patients with chronic constipation, who take up uselessly the time and energy of the clinic physicians, which might better be given to the adequate and conscientious examination and sifting of the new cases applying for treatment.

Acute bronchitis.—Next in order of frequency were the cases of acute bronchitis, including those which occurred during epidemics of grippe. Of these there were 195 or 11.4 per cent. In this group may properly be included the cases of acute laryngitis, making a total of twelve per cent. Most of these reached us in the stage of subsidence, when the expectoration was abundant and the condition improving.

Nervousness.—There were 120 cases of headache and nervousness or seven per cent. of the total, who were under observation for a varying period to ascertain the possible existence of an organic cause. None could be discovered.

The assignable cause in most of these was economic stress. Frequent causes also were unhygienic conditions in the place of employment, worry over

low wages, and the apprehension of discharge from work. Some of the patients realized that their nervousness resulted from poverty, with indebtedness for food and other commodities, or with a large number of minor dependents in the family. Other cases revealed domestic or social friction growing out of ignorance and ill adjusted temperament. It was these cases of nervousness that recruited the lists of our social service bureaus.

Pulmonary tuberculosis.—There were forty-two cases or 2.4 per cent. of pulmonary tuberculosis, most of which had positive sputum examinations. Eighty patients who presented vague symptoms were under observation as suspects. Some of the latter came primarily to assure themselves of their state of health. Thirteen of these were referred by public schools and charity organizations.

Clinical and sociological research.—If properly and conscientiously administered, a medical clinic can be made to serve as a teaching institution for the attending physician and his associates and offers excellent opportunities for clinical study. We were able to undertake a few problems of clinical research naturally limited in their scope, which we are still pursuing and concerning which we shall report later.

That the poverty and unfavorable home conditions of dispensary patients are reflected in their personal cleanliness as well as health, is shown by the great frequency among them of pediculosis capitis. Of 237 consecutive patients whose hair we examined for nits and pediculosis, only fifty-nine, or twenty-five per cent., were clean, while 172, or seventy-five per cent., showed a various degree of abundance of vermin. At the same time there were examined for pediculosis 150 girls of the same economic level working in a department store in this city, and it was found that seventy-five of them, or fifty per cent., showed vermin in the hair (1). This lesser figure is due probably to a greater diligence in the attempts at eradication by the younger visitors who have more social contact. In the clinic we distributed leaflets issued by the department of health instructing in a method of eradication.

An interesting problem presented itself to us during the period of active propaganda in this city on the subject of birth control. Many mothers came to seek instruction in the subject. Disregarding the statute existing in the State of New York, however, we undertook a scientific study of existing conditions as revealed by a verbal questionnaire which we devised. This showed some interesting facts and situations which we hope to publish as a separate study later.

Life Extension Institute.—A powerful stimulus was given to the movement for periodic physical examination of all visitors by the Life Extension Institute and the Department of Health of the City of New York. S. S. Goldwater, former commissioner of health of New York, characterized the movement as "the next step in preventive medicine." We desired to estimate to what extent a general dispensary clinic may serve as a centre for such periodical physical examinations and to note what benefits may accrue to the patients from the system we inaugurated in our own class.

It is the function of preventive medicine to prevent disease; not to prevent disease in some places, in a limited number of individuals, at certain times, but to prevent disease wherever, by the intelligent application of the principles of medicine and hygiene, disease is preventable. No program which is less comprehensive than this will suffice. And in the case of those diseases which are not wholly preventable, but the progress of which can be arrested or stayed, the task before us is to discover the first sign of departure from the physiological normal path, and promptly and effectually to apply the brake (2).

Doubtless it is generally appreciated, and in fact tacitly implied by Goldwater that there are many obstacles to the carrying out of so high and excellent a standard. The crux of the difficulties, however, appears to be in the last phrase, "to apply the brake."

In our dispensary cases, most of the ailments, even excluding the functional complaints, were early physical defects or curable maladies. We attempted periodical physical examinations during two years, and desire to make some observations on the work.

We often discovered the first signs of departure from the physiological path. We often felt that certain cases were inedically remediable and we recorded the slight abnormalities which time might correct under proper hygienic conditions, good food, a necessary amount of rest, and medical attention.

But most often we found ourselves helpless against existing conditions. We were confronted by a lamentable economic situation which permitted no correction—certainly not by mere preaching or teaching in a clinic. To "apply the brake" in these cases meant a complete change in the mode of life of the person. We had to call on our social service bureaus and municipal charities to help us to ameliorate conditions. We found that there existed a vicious circle, which created and maintained the conditions calling for correction.

III. THE NEED OF A SPECIAL CLINIC FOR CASES OF HEART DISEASE.

There were sixty-six cases of chronic heart disease, or 3.8 per cent., including chronic endocarditis, myocarditis, auricular fibrillation, angina pectoris, aortic aneurysm, etc.

For almost all these cases we found dispensary care in a general clinic inadequate, and this despite the fact that we devoted much time and attention to these patients. The amount of time these patients required was out of proportion to their number. They came for frequent examination and lengthy consultation. We endeavored to impress upon them the importance of comparative rest as the essential factor in the treatment. We reiterated detailed instructions as to the exact mode of living, and helped them to direct and plan their activities. We advised them of the only relative value of medicines.

Under concurrent favorable circumstances, these patients might remain *in statu quo* for years and enjoy life in comparative comfort and independence. In our endeavors to benefit them, however, we again met with antagonizing home conditions. Most of the patients were at work at occupations unsuited to their state of health, with little prospect of convenient change. Women with large families could not, with ease, take complete rest in bed for several hours each day; nor could they manage the

other details of their day's activities with an intelligent view to the state of their heart disease. We studied five children of school age, for whom climbing the school stairs was distinctly harmful.

The proper conduct of their life, the relative amount of rest necessary, the suitable adjustment to economic and industrial conditions demanded special education and guidance. The patients could not acquire this from a few minutes of advice in the clinic, no matter how definite and emphatic that may have been.

For the more advanced cardiac cases, permanent stay in a "home" proved to be the best solution. But as beds were not usually available, it was difficult to find means of adequate treatment.

For the early and milder cases of heart disease, we believe, there exist two phases of therapeutics which ought to be developed, and which can be done systematically with great benefit. These two methods are, 1, the educational, and, 2, the supervisory.

1. *The educational method.*—The time to advocate a system for the educational treatment of cases of heart disease deserves a separate and fuller discussion than is permissible in this paper. We shall therefore merely mention some of the conditions upon which the idea is based. We believe that all patients with heart disease should receive a hospital education, especially when the disease is first discovered, just as patients with incipient tuberculosis do in a sanitarium. By a hospital education is meant a sojourn for a period of two to four weeks. During this time an estimate can be made of the patient's capacity for action, and he can be shown how to adapt his life to his capabilities for physical work.

Inasmuch as this method, so far as we know, has not been definitely tried, our judgment may be based on analogous attempts in more advanced cases treated in the homes for chronic invalids and in general hospitals. We have seen patients who paid no attention to their malady, which they knew to exist, after a stay in the hospital lead a life altogether different from before. They recognized the importance of prolonged rest, were able to estimate their capacity for work, and learned the details in the management of their disease. This we have seen to be a most excellent means of education for bettering and prolonging the lives of these patients.

It seems to be the policy of most general hospitals to admit only decompensated or urgent cases. We had the sad experience of observing a few patients who were referred to the hospital while able to be up and about, admitted when they were decompensated and remain there for a long period, unable to recover. This seems to us wrong, both medically and economically. Medically, admission of compensated cases would be of value as an education for the patient for the proper control of his disease. Economically, stay in a hospital would save many months of occupancy of a bed later; since many cases would never become decompensated or not until after a much longer period.

The educational method, we believe, combined perhaps with the supervisory system, is the next step in the treatment of heart disease.

2. *The supervisory method.*—An associated or an alternative method is offered by the supervision of patients with heart disease at their homes by a physician and nurse associated with a special clinic where the cases can be studied. Such a clinic should provide ordinary medical equipment and special medical training. It is obviously desirable to have an electrocardiograph, or at least a polygraphic machine available for the study of special cases. A little of this work in special clinics has already been done in this city with some degree of success. It appears, however, to be an important need in every large hospital.

According to public health statistics, more people in New York city die of heart disease than of tuberculosis, and the death rate from heart disease is increasing steadily from year to year.

Under the present social conditions, patients with heart disease, like the aged, are compelled to maintain the struggle for existence with healthy people. We know, *à priori*, that they must lose out. Recognizing this as a reality to contend with, it may be a correct idea to attempt to segregate cardiac cases into an industrial sphere of their own.

In the industries, principle asserts the transfer of employees from one kind of occupation to another more fitting their state of health (3). This results in an adaptation of the individual to his work; but even so, his prospects of progress and gain are far below those of a normal person. From the broadest standpoint, therefore, our advancing intelligence should dictate to us to unyoke those to whom only disaster can result from strenuous effort of any kind. It is our conviction that the principle to be followed by the physician in his attitude toward the life of an incurable cardiac patient should be, not that of developing physical usefulness or productive efficiency; but that of the prolongation of life and the encouragement of pleasure. We might lay it down as a reasonable plea that the cardiac should indulge in as much pleasure as will be harmless to his organic condition. In fact, if we substitute the word "may" for "should," this will apply universally.

In order that the patient with heart disease may be able to do this, it is necessary that he have advice, instruction, and supervision in a special clinic for the study of such cases, and at home by the nurse of the clinic.

IV. *The need of dispensary class reports.*—Though this study was primarily undertaken as an analysis of an individual clinic, it occurs to us that this paper may achieve much if it serves as a suggestion that the head of each clinic be required to make an annual or biennial report for publication in order to stimulate progressive work in the dispensary classes.

We desire to express our thanks to Dr. S. S. Goldwater, superintendent of the Mount Sinai Hospital, for his cordial encouragement and kindness in reviewing this report. We also wish to thank Dr. Joseph Heine for his capable, energetic, and diligent assistance in the clinic.

THE SPINAL FLUID OF NORMAL CHILDREN.

A Preliminary Report,

By Orlando H. Petty, M. D.,
Roxborough, Philadelphia.
Instructor in Medicine, Jefferson Medical College; Pathologist to St. Timothy's and Germantown Hospitals.

The now abating epidemic of acute meningoencephalo poliomyelitis will doubtless give additional information as to the pressure and composition of the spinal fluid in this disease, and increase the interest in the study of spinal fluids in all forms of meningitis.

Having personally procured and examined spinal fluids in nearly fifty cases of infantile paralysis in private homes, I was impressed with the fact that the fatal and severer forms of the disease as a rule showed a lower pressure, i. e., fewer drops a minute from the spinal needle, than the apparently milder types of the disease. This brought up the question of the normal fluid, its pressure in mm. Hg., the number of drops through the spinal needle at different pressures on a mercury manometer, and its composition.

Detailed records of the normal in a large series of cases I could not find, so I have started the study on a series of normal children, a child being considered normal if it gives no history, and shows no symptoms of cerebrospinal disease.

The number in this series is yet too small to furnish reliable data, being a few less than twenty, but the average results are almost startling. They are as follows: Pressure close to twenty mm. Hg.; cell count approximating eleven cells per c. mm.; and the number of drops of spinal fluid a minute usually being above seventy-five. Up to this time the normal pressure has been considered as from six to eight mm. Hg., the number of drops a minute as about twenty, and a cell count above six per c. mm. as pathological. After a sufficient number has been studied to determine a constant average, they will be reported in detail, showing pressure as recorded by a mercurial manometer, both with and without general anesthesia, drops a minute with gauge of needle used, and cell count.

PUBLIC HEALTH.

The Duties of a Health Officer,

By Harry Greenstein, M. D.,
New York.

The greatest problem of the modern age is the health of a community. Every individual should be taught to do his share; the physician owes it to the community in which he resides. He must be a student of sanitation and hygiene.

It is the work of a health officer to trace and detect the origin of all diseases. A person holding this important and responsible position of trust must be alert, up to date, and well informed on all the subjects that will assist him in removing and preventing the spread of disease.

Disease is the result of some noxious influence, and may be of long or short duration. It may result in complete recovery, or loss of function of one or many parts of the body. It may result in impaired action or death. Disease may be carried from one person to another in many different ways: By contact with one suffering from an infectious or a contagious disease, or with one who has recently recovered from disease. It may be carried in the clothing of persons who have been in contact with the patient during the period of sickness and convalescence, or by domestic animals about the household, or by insects, such as lice, bugs, and flies. It is often carried indirectly through food and water.

Any person that carries disease to another person is a carrier. A carrier harbors the organisms of disease in his body, and is capable of transmitting that disease to another person, although he may be entirely free from the symptoms of that disease. He may have recently recovered, or have had the disease a long time previously; but still is not free from the causative organism.

The greatest danger is from the latent carriers, for they are free at times from the organism, which remains quiet, does not develop, and is harmless, but becomes virulent when immunity is broken down. Such carriers are responsible for most of the sudden outbreaks of infectious diseases.

Every one bears in the blood a power that is resistant to the virulent organisms that cause disease. This power is known as immunity. It is natural or may be acquired. By natural immunity, we mean that this power is inherited to a greater or less extent. It may appear early or late in life. It is for this reason that many persons pass safely through epidemics of disease. Acquired immunity is not inherited, but is obtained by recovery from a disease, or by inoculation of vaccines, virus, or serum. All human kind is susceptible to disease, some more than others; none are immune to many diseases, none are free from all.

Immunity is broken down by disease, by exhaustion, by excess of alcohol, by exposure to cold and wet, by lack of ventilation, and by insufficient food and loss of sleep.

When a disease spreads over a large area of a community it is called an epidemic. Epidemics are sometimes difficult to check. It requires a considerable amount of time, energy, and money before it is under control. An epidemic of measles, typhoid fever, scarlet fever, diphtheria, chicken pox, smallpox, infantile paralysis, or influenza may spread rapidly over an entire town, and infect so many that the schools and factories must be closed and houses quarantined.

During the course of the epidemic many lives are lost; many persons become infirm. Many must be isolated, segregated, and placed under strict and forcible quarantine. They must be watched until convalescence is complete, and they are no longer able to infect another person with disease. Quarantine is the detention, isolation, and segregation of persons until all signs and symptoms of disease are gone, and there is only a minimum chance of transmission to another person.

We all know that infectious and contagious diseases are due to some virulent organism. By viru-

lence is meant that the organism has the power to transmit infection. Organisms are transmitted by some outside source, man, lower animal, or insect. The greater the number of organisms in the body, the severer the disease, and the more serious the outcome.

The organisms, having invaded the system through some of its many tracts, such as the nose, eyes, and ears, by inhalation or by ingestion, or by way of the broken skin, multiply rapidly in the human body. When they are excessive in number, the disease has a short period of incubation, that is from the time of invasion until the full development of the disease. This may be a few hours, or several days.

The clothing and premises used and occupied by patients should be disinfected and cleansed daily. All the woodwork in the sickroom should be scrubbed with a hot solution of washing soda. Windows are opened for the free circulation of air. The room must be properly heated and ventilated, free from draperies and excess furniture. No dust should be scattered about the room by broom or duster. Wipe parts clean with damp cloth. After quarantine disinfect with fumes of sulphur or formaldehyde, the amount of material used depending upon the size of the room. All loose wall paper should be removed, the rest scraped off and covered with new material. The walls may be painted, and the woodwork painted and varnished.

Imagine what time and money are lost through disease to the wage earner. He is kept under restraint, is quarantined from family and friends. His family may soon be in want and they become dependent upon others for support and maintenance.

New York State has taken a step forward and has for its motto: "Public health is purchasable. Within natural limitations, a community can determine its own death rate."

THE HEALTH OFFICER.

The duties of a health officer are many. He must keep the public informed of his work, and notify them when an infectious or contagious disease becomes epidemic. He must tell of its presence, its nature, its mode of transmission, and methods used for its destruction and elimination. He must conduct a house to house canvass, through physicians, inspectors, and nurses. This canvass is made for the detection of the sick, missed cases, hidden patients, neglected cases, and carriers. Any person not under treatment, or one who refuses to obey the rules and regulations set down by the sanitary code, or adopted for the time by the health officer, may be forcibly removed by police power.

The health officer must have under his control, all properly conducted hospitals, tents, and detention camps. He must avail himself of all known means of advertising that the news may reach the public.

Every available place and person is used to notify the public as to what is going on, and what is necessary to do, so as to aid in controlling and checking the disease.

The management of an epidemic requires skill and executive ability. It must be invested in the hands of a competent physician, who should have proper authority and full control. He must have a vast knowledge of infectious and contagious diseases, know their mode of transmission, and methods for their destruction.

He must carefully organize his squad of helpers, and have under his control all physicians, inspectors, nurses, attendants, bacteriologists, and chemists that are required to carry on this work. He must be provided with hospitals, detention camps, tents, and available public and private places in which to house the sick.

In order to make the work much easier, and prevent overlapping and duplicate records, the area is divided into sections, each district in charge of a competent physician, who in turn is responsible to the quarantine officer.

There must be a strict and unbroken quarantine during the period of incubation, and attention given to segregation, isolation, sanitation, and disinfection. None should be discharged until convalescence is complete.

It is of the utmost importance that care be taken of everything that goes in and out of the kitchen, its utensils, food, water, milk, and laundry supplies. Food must be covered and protected from dust, dirt, flies, insects, and rodents, and, above all, from frequent handling.

Abstracts and Reviews

THE ROLE OF FAT IN DIABETES.*

By F. M. Allen, M. D.,
Hospital of The Rockefeller Institute,
New York.

Doctor Allen briefly outlined the many new methods of analyzing the blood quantitatively for its various normal and abnormal constituents, and stated that it was the development of these methods which had made possible in large measure the study of the problems upon which he was to report. It was a tribute to American science that every one of these tests was devised or perfected by an American investigator. Finally, the possibility of better study of the problems of diabetes was greatly increased by the ability to reproduce in dogs conditions almost identical with those encountered in human diabetes. This could be done by the surgical removal of a large proportion of the pancreas, leaving the remainder in communication with the intestine through the pancreatic duct. This operation rendered the dogs diabetic, and yet retained their digestive functions through the preservation of the pancreatic secretion.

The first point in the problem of the role of fat in diabetes was that of lipemia. This condition was almost a constant finding in severe human diabetes and might be present to a slight degree even in very mild cases. The same was found to be true in partially depancreatized dogs. Further, diabetes in man and the partial depancreatization of dogs were the only conditions in which a high degree of lipemia was found. The fat might be present in the

*Summary of a lecture delivered before the Harvey Society at the Academy of Medicine, New York, November 4, 1916.

plasma of severe cases in either man or the dog in amounts up to fifteen per cent. or over, and the ability to produce the condition in the latter afforded ideal conditions for the study of its causation and significance. It had long been believed that lipemia was due to a diminution in the lipase present in the blood, but this could now be stated to be incorrect and we could safely regard the lipase as quite a negligible factor. It had been shown in experimental dogs that lipemia varied in degree largely with the digestive power of the animals, that the fat was derived in great measure from the food fats, and that lipemia could be controlled largely by feeding. The fat in the blood was chiefly neutral fat with a considerable proportion of cholesterol, which ran parallel to the former, and a small amount of lecithin.

As to the causation of lipemia, experiments on the partially depancreatized dogs made it possible to say definitely: 1. Lipemia was not due to the occurrence of hyperglycemia. 2. It was not due to the absence of carbohydrate or to the loss of sugar. 3. It was not due to the presence of acetone bodies or to the change in the reaction of the blood. 4. It could not be produced by simple overfeeding with fat. Its exact cause was as yet unknown, but recent studies in the author's laboratory seemed to point to its being related in some way to the condition of the cells in the pancreas, and evidence was accumulating which indicated that there might be an internal secretion of that gland which was directly concerned with the production of lipemia.

The second problem in the role of fat in diabetes was concerned with acidosis. Before entering into its discussion, it was necessary to have a clear understanding of what was meant by acidosis. In the author's opinion the term should be restricted to the original definition given by Naunyn, which stated that its one constant characteristic was the occurrence in the blood of an abnormal amount of beta-oxybutyric acid and acetone bodies. Contrary to the present misuse of the term it had nothing to do with a simple displacement of the reaction of the blood, and conditions with diminished alkalinity, increased carbon dioxide tension, increased hydrogen ion concentration, and reduction of the "buffer" salts should not be classed as acidosis, since such a classification led to confusion.

Here, as in lipemia, the precise ultimate cause of acidosis is not known. It was fairly certain, however, that fat played an important role in its production and that the acids were produced largely in the muscles and liver—organs in which fat was burned. It was not yet known what proportion of fat could be burned without the production of acidosis in subjects with diabetes, or what proportion of carbohydrate was required to prevent the development of acidosis. It could be stated positively, however, that acidosis was not necessarily due to a lack of carbohydrate. If it was not possible to state the ultimate causes of acidosis at least the study of the partially depancreatized dogs had made it possible to gain an insight into some of the more remote causes.

It was found that acidosis could be produced in such dogs in three ways, all in complete imitation of the conditions encountered in man. First, it could be produced by following the plan adopted in the usual clinical treatment of human diabetes, namely, by giving a diet of high caloric value and high fat content. If an experimental dog with diabetes be made to hold or to gain weight—which is the practice in man—fat must be introduced into the dietary and calories must be crowded. One of two things soon happens in the dog; either he begins to vomit and suffer from diarrhea with loss of weight and refusal of the food, or, if the feeding is forcibly continued, his metabolism breaks down. When the latter occurs true acidosis develops and a fatal diabetic coma quite similar to that in man ensues. Such a diabetic coma can be produced in these animals while they are thus kept on a full diet, and this is just what occurs in human beings. Secondly, if the treatment employed in moderate human cases be applied to these dogs, the same results will ensue as in the first case. This is the fattening treatment which is marked by a reduction in the intake of protein and the administration of fat. These dogs look extremely well, but they go on to a fatal acidosis. The third way is that in which the animals are kept free from glycosuria through the administration of a diet very low in carbohydrate and consisting mainly of fat and protein. This form of diet is also often prescribed for man.

In both man and in these animals if the condition has not gone too far the acidosis may be checked by the introduction of a period of fasting, but if the diet is restored, the downward progress will continue. In severe cases—human or animal—the fasting may at first increase the acidosis, but if the fasting is repeated with periods of return to a properly adjusted diet, it is usually possible to produce an immunity to the fasting acidosis and an ultimate recovery of very marked degree. These observations, along with others, the details of which cannot be given, all point to the existence of some specific internal function of the pancreas which is concerned with the production of acidosis. They also show that an alteration in the reaction of the blood is not the cause of death in acidosis, for the blood may be kept normal in reaction by the proper administration of alkalies, and yet the man or the animal may die of diabetic coma and typical acidosis.

If periods of fasting are properly introduced and the diet is adjusted, it is possible to keep the human or animal patient in a condition of physical comfort and fair health for long periods of time and ultimately to increase his tolerance for foods to a great extent. It was also pointed out that the craving for carbohydrate seen in many diabetics was not due to "original sin," but was a physiological demand for that food element which does the most perhaps to control the development of acidosis. The same craving was to be observed in an intense degree in the dogs suffering from acidosis.

The last point to be discussed was the value of fat in the dietary of diabetics, and it was shown that fat unbalanced by other food constituents was a poison. The essence of these observations was to show that it was necessary to preserve a natural balance between fats on the one hand and protein and carbohydrate on the other if dangerous complications were to be avoided—especially acidosis and coma.

The net results of the observations pointed to the absolute necessity for clearing up the lipemia of diabetes; to the need of a proper appreciation of the importance of fat, unbalanced by other foods, in the production of acidosis; and finally to the most important fact of all, namely, that in diabetes there was a deficient assimilative function and that efforts to maintain the body weight by high calory feeding would soon lead to an exhaustion of whatever function remained to the patient. The true lesson to be learned was that it was not fat alone, not protein alone, and not carbohydrate alone which was the source of danger, but that it was a disturbed balance between all three combined with an overtaxing of the patient's assimilative powers which led to the downward progress of diabetics under the usual plans of dietetic regulation. Depending upon the severity of the case, the load on his assimilative function should be lightened; if he had acidosis he should be starved, once or repeatedly, until his assimilative function could be restored; and his diet should be kept within his assimilative capacity. If such a plan was followed, the majority of patients would live in comfort, and a large proportion of them would ultimately show a decided increase in the extent of their assimilative capacities.

Contemporary Comment

Boards of Health.—The Rhode Island State Board of Health, says the *Providence Medical Journal* for November, 1916, is to be commended upon the efficiency and sanity of their attitude toward the epidemic of infantile paralysis which has struck terror to hearts of the parents of children throughout the areas afflicted. The sensible investigation of unrestricted visitors to the State and the subsequent observation at their point of destination is in pleasing contrast to the rigid and therefore inefficient quarantine and uncertain control as instituted in neighboring States. It is in no spirit of hostile criticism of the State Board of Health that we express the following opinion, and so at the risk of becoming the target of a whole hodful of "editorial bricks," we make bold to suggest that the public health of a community will be better served by a single health commissioner than by a large board made up of physicians in general practice. It is, we admit, a "bromidiom" to say that this is an age of specialism, but in no department of medicine is it more true than in public health. The State of Rhode Island should engage at a salary sufficient to demand his full time a trained sanitarian of the type exemplified by Gorgas of the Panama Canal. He should be given supreme power in matters of public health and control, free from the baneful touch of party politics, over the subsidiary departments of food and drug inspection, sewage disposal, quarantine, etc. The time demanded, the scope of the problems to be met, the rapidly increasing control by the State of matters formerly considered of purely individual concern will make it impossible for us who make our living in private practice to serve the State as it will soon demand its health officials shall serve. Doubtless this same thought has occurred to the members of the board themselves, many of whom have served long and well at the expense of their own valuable time and comfort. It is to be hoped that before long they will take steps to initiate legislation which will put the health affairs of Rhode Island on a strictly modern basis.

Modern Humanitarianism.—The present era is permeated with a strong sentiment of opposition to cruelty in every form, observes the *Illinois State Journal of Medicine* for November, 1916. On one hand we see the greatest philanthropic organization in the history of the world devoted to the relief of suffering in Belgium. Another aspect of this sentiment is the modern idea that crime is largely due to mental defect or disease on the part of the criminal. The refinements in the diagnosis of feeblemindedness enable the courts to separate these victims of heredity from the criminals due to vicious associations. But few communities are prepared to follow these offenders to the logical conclusion, viz., permanent confinement with self supporting labor. If the present trend continues, the prosecution, in addition to overcoming the "presumption of innocence," will also have to assume the probability that the culprit is mentally irresponsible!

An Intelligence Test in Brooklyn.—That one of the candidates for a Supreme Court Justiceship in the second judicial district, voted upon at the election, happens to be a physician, observed the *Medical Times* just before election day, is something the significance of which may not be wholly apparent either to the profession or to the public. A medical man takes with him when he enters great fields of human service other than medicine much of what he assimilated, as a practising physician, of our traditions and principles. This is a splendid heritage. If to other qualifications for the exalted office of Justice a man adds the peculiar knowledge of men and of science that medical practice develops, it would seem that the political powers that be are doing their very best for the people when they conscript a candidate so equipped, for it is obvious that a man medically trained is preeminently qualified to adjudicate cases having a medical phase, and we are all aware how large a proportion of the mass of litigation such cases constitute. Surely the people would profit through the special insight that a medically informed jurist takes to the bench. For ourselves, we should say that it is most desirable that the profession be represented more largely in high civic office of every grade. Our interests would be safer in every way were this the case. All possible checks should be placed upon the nuisances who appear bent upon placing mines under the very temple of our art. Such representation as we advocate would add to government the intelligence which is all that is needed to wreck the wreckers themselves.

We hope that both the profession and the public in the district concerned will take advantage of the opportunity now offered to suspend partisan considerations, where such exists, to the ends for which we plead.

RACE SUICIDE.

The commission which has been investigating the causes of infantile mortality in Great Britain recently handed in its report. This document is interesting because, while it draws no hard and fast conclusions, it allows it to be understood that the members incline to the view that the main cause of the falling birth rate is the artificial means taken to prevent conception. This is, in effect, what is known as race suicide. The war in Europe, with the appalling slaughter of its most virile and energetic men, at the time of life when their physical and mental powers are at their height, has concentrated attention on the generally declining birth rate and on the best means for preventing its continuance. The phase of the situation of especially alarming import is that it is the flower of the race that is being killed, maimed, and crippled on a wholesale scale. Those who are left are, as a rule, not the best stock with which to propagate the species. In fact, physically and mentally they are inferior, and their progeny will be of a lower standard than the former generation.

In the *Hibbert Journal* for July, 1916, the Countess of Warwick discusses "race suicide," and although she deals with it mainly from the economic standpoint, she makes some exceedingly good points. She attributes its increasing prevalence in civilized countries to the methods of life that soften women and make childbearing a terror. Primitive and hardy agricultural people are not troubled by fear of childbearing. They raise large families and retain their good looks as well as their health. Luxurious living and ostentation are largely responsible for the small families among the very class which should be the bulwark of a country. The most prolific people are those who are usually regarded as the least desirable elements, that is to say, the least intellectual, the most ignorant, and those who have in them the most of the animal and the least of the spiritual.

Lady Warwick points out what now seems to be a more or less obvious truth, that the solution of the problem, whether the educated and skilled classes, that is, the skilled artisan and working classes, are going to propagate the race in such a way that they may not be swamped by an inferior people, is in the woman's hands. It lies with her to decide, to a very large extent, the destiny of the white race, for it must be borne in mind that the black and yellow races are extraordinarily prolific.

Father Vaughan, writing in the *Nineteenth Century* for September, 1916, referring to the decrease of births among the better elements of the population, notes that M. Jacques Bertillon, the eminent French statistician, gives a table showing the annual births of 1,000 women, aged from fifteen to thirty years, in different quarters of Paris, Berlin, Vienna, and London, representing six grades, from the very poor to the very rich. In all these four capitals, fertility is greatest among the poorer classes, while it gradually diminishes as comfort and luxury increase.

Thus the situation with regard to the declining birth rate in the majority of civilized countries, appears to be somewhat as follows: The birth rate has declined and is declining most quickly among the professional classes and the skilled working classes. The fertility of the poorer classes has not been appreciably affected. According to many authorities, and their views appear to be borne out by the recent investigations of the British Commission on the Decline of the Birth Rate, the decrease in childbearing is largely brought about by artificial means.

Obviously, conditions in this country cannot be compared with those in Europe, as the war by decimating the male population has rendered the situation there peculiarly acute. The birth rate in America, however, has declined among the professional classes and to a lesser extent among the work-

ing classes, and presents a serious problem of our own, the solution of which will tax the brains and energies of the thoughtful of all classes, especially of members of the medical profession. Malthusian doctrines may be all very well as far as they go, or when they work out as intended, but not when their results are to check population among the professional and skilled working classes, while the teachings are not known, and have no effect upon the poorest members of the community.

Whatever may be the causes of a progressively declining birth rate, the matter should be thoroughly probed, so that at least we may know how and where we stand.

THE FINDING OF ACTIVE LESIONS AND SPIROCHETES IN CLINICALLY INACTIVE OR CURED SYPHILIS.

The frequency of latent syphilis of the heart, aorta, and nervous system is known to all pathologists. Whereas previous to the discovery of Spirochæta pallida, pathologists diagnosed syphilis post mortem by certain characteristic lesions, especially of the myocardium, aorta, and testicle; since the recognition of the cause of the disease, they have no right to declare that a certain lesion discovered post mortem is syphilitic unless the spirochetes are found. It is right, therefore, that Warthin, of Ann Arbor, in an instructive paper on The Persistence of Active Lesions and Spirochetes in the Tissues of Clinically Inactive and Cured Syphilis (*American Journal of Medical Sciences,* October, 1916), should plead that "the methods for the demonstration of this organism in the tissues should be made a part of the routine autopsy microscopic examination," he himself advocating the Levaditi method for the demonstration of spirochetes.

It is advisable that the tissues be removed from the body, within one to two hours after death, that they be immediately fixed in ten per cent. formol for not less than twenty-four hours, but preferably for three days, and that they then be put through the Levaditi method and blocked in paraffin. For hardening purposes a formaldehyde solution neutral in reaction that has not been kept in wooden casks should be employed.

The facts recited by Warthin are so significant that they will bear recital. In the pathological service of the University of Michigan, from 1912 to 1914, forty-one autopsies were performed; one third of the adult cases presented active lesions of syphilis microscopically, as evidenced by the presence of spirochetes or characteristic tissue lesions. In the latter group (those with characteristic tissue lesions, but apparently without spirochetes), Spirochæta pallida, as the result of more systematic and thorough examinations, is now being found with increasing frequency, and the work is still in progress.

In a majority of cases there had been no suspicion that lues existed in latent form, the history being negative; in a certain proportion in which lues had been suspected or even diagnosed the treatment previously instituted had apparently been considered sufficient; and in a small group even the most modern methods of treatment were instituted with the ultimate announcement of a clinical cure. It may be mentioned with regret that the Wassermann test was not done in all of these cases, since, as the author informs us, it was only during the past year that a routine test was done on all patients entering the hospital. Of the cases cited in this report, Warthin found eleven with a clinical diagnosis of lues regarded as clinically cured, five with active lesions and under treatment for manifestations, and twenty-five with luetic infection excluded clinically owing to the absence of symptoms and the denial of infection.

In all these cases, no matter what the exact clinical diagnosis or condition had been, the lesions of active syphilis discovered post mortem by histological examination, were essentially of the same nature. Active lesions of syphilis were reported in the heart in thirty-six cases, in the aorta in thirty-two, in the testes in thirty-one, in the liver in four, in the adrenals in six, in the spleen in one case, in the pancreas in six cases, and in the central nervous system in five; and this in spite of the fact that in the majority examination of the brain and spinal cord was not permitted. Furthermore, Warthin found twenty-three cases in all of nephritis; just how many of these were due to lues cannot be stated. It is well to remember, as Warthin tells us, that, pathologically, "the triad of interstitial myocarditis, aortitis, and orchitis fibrosa may be taken as a pathological complex indicating the occurrence of a syphilitic infection in the male." In the female he examined for lesions in the heart, aorta, pancreas, and adrenals.

The astounding general propositions as a result of Warthin's findings are that in about one third of adult cases lues was found post mortem in persons who had entered the hospital for other conditions, especially cardiovascular-renal syndromes. Furthermore, although most of the lesions found are to be considered as healed or fibroid syphilitic areas, yet, if the microscopic search is thorough, active areas of inflammation can be found in all, with the same histological lesions, of the same degree and extent, and in the same organs.

Warthin's final conclusions are decidedly interesting. He believes that we must regard lues in the same light as tuberculosis. Concerning syphilis we may say that it is a great factor in destroying the health and hindering the progress of the race, that myocardial insufficiency and cardiovascular-renal diseases are due to latent syphilis as one of the chief factors, and that spirochete carriers are persons with a latent infection of very low virulence, and as such are bad insurance risks.

As regards possible reinfection, Warthin does not believe that this plays any role in the cases he has reported, and reminds us that the chancre may recur in late active and treated cases of lues. Some of the latent cases are due to congenital or familial lues, clinical symptoms of which may be entirely absent throughout the lifetime of the carrier of the spirochete. In addition, a negative Wassermann does not necessarily mean the absence of latent syphilis.

Finally, it is important to know the conditions that are responsible for the renewal of the activity of inactive spirochetes. From the standpoint of treatment this means that "the syphilitic must be treated as a germ carrier," and general hygiene is of as great importance for the spirochete carrier as for the subject of latent tuberculosis.

Warthin's conclusion that even the most modern methods of treating syphilis probably do nothing more than render the infection latent and do not really cure, strikes a positively pessimistic note to the clinician. Warthin speaks as a pathologist. If he states the truth, we must face it and recognize it as such. It is well known, however, that the clinician is more apt to be optimistic than the pathologist, and it would be interesting to hear an authoritative expression of opinion from the other side. The problem under consideration is of sufficient importance to demand this.

THE ORIGIN OF LIFE.

If there is any theory of the origin of living things which seems to have a semblance of truth, it is that of a spontaneous chemical beginning. What conditions were in the primeval earth we do not know, but they were certainly more conducive to elaborate chemical changes than now. There were higher temperature, more substances in solution, and less stability generally.

It is only two centuries since many scientists believed that eels developed from dew, but that large animals or plants arise spontaneously has now become unthinkable. As we approach the lower forms of life, however, our assurance in this matter certainly becomes less strong, and especially does the spontaneous origin of life which is neither animal nor vegetable seem possible. The discovery of the filterable bacteria seems to bring us nearer to a beginning of life, for not only must the first living things have been simple in form, but they must have been extremely minute. These filterable organisms are certainly not larger than the particles shown by the ultramicroscope in the protoplasm of living cells, and which by some are called "giant molecules." Certainly there seems little about them to justify the application of the term, organic. Again, some bacteria have made their appearance suddenly, or at all events have come to influence human life in a brief time, and then have as abruptly passed from the scene or at least changed their nature decidedly. Diseases in the past have arisen suddenly and disappeared as mysteriously. Poliomyelitis seems hardly to have been known before 1840.

The development of epidemics shows us that there is much to be learned about conditions affecting living things, especially bacteria. If we knew these secrets, we could check or prevent epidemics, and we should come much nearer knowing the origin of life.

Some thinkers have gone so far, though it is not very far after all, as to believe that all matter is, in a way, living; that it contains within it the energy which, when displayed under certain forms, we call life. Certainly if we except mental phenomena, there is no form of energy put forth in the living thing that is not obtained from "dead" matter, and even mental phenomena depend upon that dead matter. Is it going too far to attribute to matter the inclusion of that which we call mind?

A RAPID AND EFFECTIVE TREATMENT OF TRENCH DISEASE.

Trench disease is a name given, by the French at least, to the severe and often infected dermatoses of the lower extremities following long standing in the battle trenches. These lesions are often surprisingly resistant, ordinary ointments having no effect, and simple aseptic dressings delaying results till patience is exhausted. In the *Journal de médecine de Paris* for September, 1916, Dr. L. Chastanet tells how he manages such cases. After removing scabs with cotton swabs sterilized by boiling, he cauterizes deeply with silver nitrate, which is not especially painful, and applies a simple water dressing. As long as the surrounding tissue retains its dark color, he continues with the nitrate, but when a pink or flesh colored tint appears, he makes one last, deep, and extensive application, including the lips of the wounds, and follows this up at once with an application of tincture of iodine, ten per cent. Immediately a "dazzling" precipitate of silver iodide appears. The wound is dried and covered with a ster-

ile compress. In the great majority of cases, the wound will be found quite dry twenty-four hours later; if not, Chastanet begins all over again. As soon as the wound is found dry, it shows that cicatrization is proceeding under the protection of the pellicle of silver iodide, which is easily detached once the integrity of the epidermis is restored. The whole process never takes longer than a fortnight.

The precipitate spoken of is in reality an albuminoiodide of silver; it is supple, elastic, and extremely adherent to the subjacent tissues. White in the nascent stage, it quickly turns yellow; daily it is thickened by the drying of the underlying secretions, until finally it peels off of itself, or is easily detached. Wounds treated in this manner are clean and look as if they were covered with a skin graft. A minor advantage is economy, as changes of dressing become unnecessary after the first satisfactory application.

THE DESTRUCTION OF HOUSE FLIES.

Formaldehyde and sodium salicylate are the two best muscicides, according to Earle B. Phelps and Albert F. Stevenson (*Public Health Reports*, November 3, 1916); both are superior to arsenic from many viewpoints. For household use, according to the writers, solutions of these agents may be prepared by the addition of three teaspoonfuls of either the forty per cent. solution of formaldehyde found on the market or the powdered sodium salicylate to a pint of water. Nearly fill a glass tumbler with the solution, place over this a piece of blotting paper cut to circular form and somewhat larger in diameter than the tumbler, and over this invert a saucer. Invert the whole device and insert a match or toothpick under the edge of the tumbler to allow access of air. The blotting paper will remain in the proper moist condition until the entire contents of the tumbler have been used, and the strength of the formaldehyde solution will be maintained. A little sugar sprinkled upon the paper will increase the attractiveness of the poison for the flies. Either of these preparations may be safely used where there are young children, although the addition of the sugar is not recommended in such cases. The formaldehyde, unlike arsenic preparations, has an unpleasant taste, and in the concentrations recommended a harmful dose could not conceivably be taken. No bad effects would result from the consumption of a considerable quantity of the salicylate.

THERE ARE EXCEPTIONS TO ALL RULES.

An anonymous correspondent of the *Lancet* for November 4, 1916, acknowledges that there is a popular and widely known belief that where there are twins of opposite sex, the girl is invariably sterile; in fact, he had been asked about his own marriage in that respect. Although his wife, however, is such a twin, she has thus far presented him with five healthy children.

News Items

Changes of Address.—Dr. Leo V. Rosenthal, to 954 South Broad Street, Trenton, N. J.

Dr. Frank R. Starkey, from Walnut and Seventeenth Streets, Philadelphia, to the David Whitney Building, Detroit, Mich.

Dr. Joseph A. Mendelson, from 3302 North Broad Street, Philadelphia, to 4012 Georgia Avenue, N. W., Washington, D. C.

Harvey Society Lectures.—The third lecture in the course will be given on Saturday evening, November 25th, by Dr. Paul A. Lewis, of the Henry Phipps Institute for Tuberculosis, the subject being Chemotherapy in Tuberculosis.

Anniversary Address of the New York Academy of Medicine.—This address was delivered on Thursday evening, November 16th, by the Hon. Chauncey M. Depew, his subject being the Art of Growing Older, and the Value of an Interest in Public Life.

The Narcotic Evil in Philadelphia and Pennsylvania.—Under this title the Philadelphia Narcotic Drug Committee has issued the report of its findings. Copies of the pamphlet may be obtained from the secretary of the committee, Dr. John H. W. Rhein, 1732 Pine Street, Philadelphia.

Northern Medical Association of Philadelphia.—At a meeting of this association, to be held in Philadelphia on Friday, December 8th, Dr. Max Einhorn, of New York, will read a paper on the Diagnosis and Treatment of Gastric and Duodenal Ulcer. The discussion will be opened by Dr. John B. Deaver, Dr. David Riesman, and Dr. Martin Rehfuss.

Columbia Wants $12,000,000.—In his annual report as president of Columbia University, Mr. Nicholas Murray Butler asked for an endowment of $12,000,000 in order to create a great medical centre. He also asked for an endowment of $6,000,000 for the dental school which was established this year, and for other endowments for the engineering departments, making a total of $30,000,000 needed by Columbia University.

Endowment Fund for Henry Street Settlement.—Announcement is made by the chairman of the finance committee of Henry Street Settlement, that plans are being made to raise a fund of $1,000,000 to enable the settlement to increase its facilities, particularly in caring for children who have been crippled by poliomyelitis. Nearly $600,000 of the fund has been raised, and several persons have promised annual contributions.

A Scientific Expedition to the Amazon Valley.—A party of scientists, headed by Dr. Alexander Hamilton Rice, left New York on Wednesday, November 15th, for South America, for the purpose of making a topographical survey of portions of the Amazon Valley and interior districts and studies of the diseases of the natives in that section. Dr. William T. Councilman, professor of pathology at Harvard University, is a member of the party.

Yorkville Medical Society.—At a meeting of this society, to be held on Monday evening, November 20th, at the Aschenbroedel Club, the program will consist of a symposium on acute anterior poliomyelitis, as follows: From the laboratory, by Dr. A. L. Garbat; Pathology and Diagnosis, with lantern slide demonstration, by Dr. Marcus Neustaedter; from the pediatrist, by Dr. Godfrey Pisek; from the orthopedist, by Dr. Henry Keller. Dr. Henry Heiman will open the discussion.

Medical Association of the Greater City of New York.—A stated meeting of this association will be held in Du Bois Hall, New York Academy of Medicine, Monday evening, November 20th, at 8:30 o'clock. The evening will be devoted to a consideration of poliomyelitis, its diagnosis and treatment. Papers will be read as follows: Tonsillectomy in Poliomyelitis Based on Rosenow's Bacteriological Investigations, by Dr. Joseph C. Roper; Aftertreatment of Poliomyelitis, by Dr. Henry W. Frauenthal; Diagnosis and Serum Treatment of Anterior Poliomyelitis, by Dr. Abraham Zingher.

Meetings of Medical Societies to Be Held in Philadelphia during the Coming Week.—Monday, November 20th, Clinical Association, Blockley Medical Society, Society of Normal and Pathological Physiology, Medical Society of the Woman's Hospital; Tuesday, November 21st, West Branch of the County Medical Society, Section in Medical History of the College of Physicians; Wednesday, November 22d, County Medical Society; Thursday, November 23d, Pathological Society, Northwest Branch of the County Medical Society; Friday, November 24th, Neurological Society, South Branch of the County Medical Society, Northern Medical Association, Medical Club (directors).

Lectures on Health Insurance.—The American Association for Labor Legislation has arranged a series of four lectures on health insurance, to be given Monday evenings, in the Evans Memorial Hall, Boston. The first of the series was given on Monday, November 13th, by Professor Irving Fisher, of Yale University, on the Need for Health Insurance. Other lectures in the course are: The Practice of Health Insurance in Europe, by Miles M. Dawson, on November 20th; on November 27th, the subject will be the Physician's Part in Health Insurance; on December 4th, Dr. John B. Andrews, secretary of the American Association for Labor Legislation, will speak on Health Insurance Legislation Now Proposed in the United States.

Poliomyelitis Clinics in Boston.—Announcement is made that the Massachusetts State Department of Health has joined with the Harvard Infantile Paralysis Commission in providing a series of clinics, to be situated in Boston and in points outside the city where physicians may bring their patients for consultation and advice as to treatment. The work of the clinics will be under the supervision of the Harvard Infantile Paralysis Commission, with skilled surgeons in attendance at the clinics, together with nurses specially trained for the work to assist at the clinics, to care for the follow up work in the homes and to instruct patients and their parents as to exercise and treatment advised. The members of the commission are Roger Pierce, Dr. F. M. Peabody, Dr. R. W. Lovett, and Dr. M. J. Rosenau. The Boston clinic will open about November 20th.

Compulsory Health Insurance.—A public meeting will be held at the New York Academy of Medicine on Thursday evening, November 23d, under the auspices of the Committee on Medical Economics of the Medical Society of the State of New York, to discuss the question of compulsory health insurance. The symposium will be opened by the chairman of the committee, Dr. S. J. Kopetzky, and papers dealing with various phases of the question will be read as follows: The Relation of Health Insurance to Preventive Medicine, by Dr. B. S. Warren, of the United States Public Health Service; the Labor Man's Point of View, by Mr. Hugh Frayne, of the American Federation of Labor; the General Medical Practitioner's Point of View, by Dr. Eden V. Delphey; the Advantages of Compulsory Health Insurance, by Mr. Miles M. Dawson, insurance expert. The discussion will be opened by Dr. Lee K. Frankel, Dr. Alexander Lambert, and others.

Health Insurance to Be Discussed in Washington.—The International Association of Industrial Accidents Boards and Commissions, a quasiofficial organization of the official bodies charged with the duties of administering compensation laws in the United States and Canada, has called a meeting to be held in Washington, D. C., December 8th and 9th, to consider the question of health insurance. The discussions have been arranged under four heads, as follows: Workmen's compensation, sickness (health) insurance and benefits, invalidity and old age insurance, and social insurance applying especially to women. The conference does not expect to adopt resolutions relating to particular policies or methods, but to define clearly the various problems demanding solution at the hands of legislators. The fee for membership in the conference, which entitles the holder to participate in the discussions and to receive a copy of the *Proceedings of the Conference*, is two dollars. Applications should be addressed to Royal Meeker, secretary-treasurer, United States Commissioner of Labor Statistics, Washington, D. C.

Red Cross Christmas Seals.—Twenty-five millions of these seals were sent out on Monday, November 13th, from the State Charities' Aid Association, 105 East Twenty-second Street, New York, for distribution throughout the State, and the sale of the seals began on Wednesday, November 22d. Buffalo has ordered 4,500,000, Syracuse and Elmira 1,000,000 each, Albany 800,000, and Troy 500,000. Last year New York won first place in the national competition among the larger States for the highest per capita sale of seals.

Mortality Statistics of New York.—According to figures given out by Acting Health Commissioner John S. Billings, the death rate for the week ending November 11, 1916, was 0.35 lower than the corresponding week of last year.

There were only seven deaths from poliomyelitis in the entire city during the past week. The total number of deaths reported during the week was 1,315, equivalent to a rate of 12.28, compared with 1,324 deaths and a rate of 12.63 for the corresponding week of 1915.

The death rate for the first forty-six weeks of 1916 was 13.96, compared with 13.91 for the corresponding period of last year. According to Doctor Billings, this is really a remarkable showing in view of the 2,000 deaths from poliomyelitis this summer and the 2,000 deaths during the grippe epidemic last January.

Industrial Medicine.—The fourth annual industrial welfare and efficiency conference will be held in the hall of the House of Representatives, Harrisburg, Pa., November 21st, 22d, and 23. On Thursday, November 23d, the medical session will be held, with Dr. Francis D. Patterson, chief of the division of hygiene and engineering of the State Department of Labor, in the chair. Dr. B. S. Warren, of the United States Public Health Service, will read a paper on Health Insurance, which will be discussed by Mr. John B. Andrews, secretary of the American Association for Labor Legislation, New York. Other papers on the program are: Medical Supervision of Workmen and Its Relation to the Prevention of Industrial Accidents, by Dr. Loyal A. Shoudy, of the Bethlehem Steel Company; Relation of the Industrial Physician to the Problems of Modern Industry, by Dr. J. W. Schereschewsky, of the United States Public Health Service; Industrial Eye Injuries and Their Prevention, by L. A. De Blois, of Du Pont, de Nemours & Co., Wilmington; Tuberculosis as It Affects the Worker, by Mr. A. P. Bowers, vice-president of the Pennsylvania Federation of Labor.

Eleven and a Half Million Dollars for Chicago University Medical School.—The General Education Board has announced that that board and the Rockefeller Foundation have jointly appropriated $2,000,000 which would be added to money and property worth $9,000,000 for the founding of a medical department at the University of Chicago. Julius Rosenwald, a Chicago merchant, has added $500,000 to the endowment of $2,000,000 which must be raised by the university under the terms of the gift from the Rockefeller Foundation. It is expected that the endowment will be brought up to the sum of $15,000,000. Dr. Abraham Flexner said that Chicago had been chosen, rather than New York, for the reason that the University of Chicago had no department of medicine now, that branch of science being taught by arrangement with the Rush Medical College: "So we will begin at the beginning of Chicago, without reorganizing an existing institution. The schools in New York, Philadelphia, and Boston, for instance, already have staffs consisting of eminent physicians and surgeons who spend part of their time in practice. It would be very difficult to reorganize them so that the staff of teachers would devote all their time to the work of the institutions. The General Education Board is in favor of the full time plan. The University of Chicago made a proposal to us which we considered favorably." It is understood that the object is to provide advanced teaching which will obviate the necessity for foreign study by American students. It is understood that the Rush Medical College will go out of existence when the new school is ready to open. The school will be erected on the Midway Plaisance and the laboratory building will be near the Presbyterian Hospital which will be part of the school.

Modern Treatment and Preventive Medicine

A Compendium of Therapeutics and Prophylaxis, Original and Adapted

THE THERAPEUTICS OF A PHARMACOLOGIST.

By A. D. Bush, M. D.,
Professor of Pharmacology and Therapeutics, University of Southern California.

Forty-fourth Communication.

CATARRHAL GASTRITIS.

Inasmuch as by far the greater number of cases of catarrhal gastritis are caused by dietetic errors, it follows that the first and principal mode of treatment should be the correction of these errors. To this end the immediate necessity is to stop *all* food and thus give the inflamed surface of the gastric mucosa a period of rest from irritation. If the motility of the stomach is so diminished that food is remaining there, fermenting and decomposing, removal of this material by the quickest, shortest route is urgently demanded; for this purpose a simple emetic like ipecacuanha in abundant water is usually satisfactory. More often, however, there may be increased reflex motility with discharge of undigested material into the duodenum; especially is this likely to be the case when the acid secretion is above normal, inasmuch as increased acidity tends toward inhibition of the pyloric sphincter. The leading indication, then, is to remove all irritating substances from the mucous membrane, thereby affording the mucosa a season of rest. This rest period may well be prolonged from twenty-four to forty-eight hours, or more in severe cases; permitting only very warm water to enter the stomach.

In some cases, where the inflammation of the mucous membrane is severe, it may seem feasible to protect the surfaces, in which case it is customary to use some of the relatively nontoxic preparations of bismuth.

A not inconsiderable number of these attacks occur with that class whose sole aim in life seems to be the pampering of their appetites. With this class, relapses and recurrences are frequent until such a time as the afflicted acquire a wholesome interest in some object outside of themselves, and set out to do something really worth while with such faculties and endowments as they may possess. With such an awakening the reflexes along both vagus and sympathetic distributions become more nearly normal, simpler food is eaten, morbid introspection is reduced, and the general tone of the whole system, including, of course, the stomach, is greatly improved.

In the convalescent stage of gastritis practically all authors recommend the administration of the proteolytic ferments, pepsin and pancreatin, apparently with the tacit assumption that a deficiency of these enzymes must exist and that an outside supply must be furnished. But in no case has it been satisfactorily demonstrated that apepsia or hyperpepsia ever exists; we have no convincing evidence that there is at any time a deficiency of pepsin in the gastric secretion or of the several enzymes of the pancreatic secretion; in fact, our present evidence is that a given food is to a large measure its own stimulant of the particular enzyme needed for specific digestion; or that satisfactory secretogogues, like meat extracts, may be administered for their inciting power. Concerning pancreatin, especially, it would seem as if its administration was useless, as in the absence of succus entericus the tryptic ferment would be inactive, and in any case it would not act in the acid medium of the stomach; hence it would probably be hydrolized by the gastric enzyme in the same manner as would any other nitrogenous body. If either of these ferments is to be used at all, the best plan would be to place it in suitable food material for some time before alimentation is demanded, and thus permit of partial predigestion; such a reduction of the proteins to peptones, or even further to the amino bodies, might readily be conceived a reasonable procedure, thereby saving the stomach and duodenum so much work, and affording an extended period of rest while yet maintaining adequate nutrition.

(*To be continued.*)

Radiotherapy in Peripheral Tuberculous Adenopathy.—E. Albert-Weil (*Paris médical*, September 23, 1916) asserts that by virtue of recent improvements in x ray technic, through which treatment can be restricted largely to the more penetrating rays of short wave length and much larger doses used without exciting dermatitis, there is now no form of tuberculous adenopathy in which x ray treatment is not indicated. The x rays melt down and cure the largest lymphatic masses, even without the aid of general treatment or heliotherapy; very rapidly when the glandular masses are semihard or recent, less rapidly but with equal certainty when they are hard and confluent. In closed suppurative cases, aspiration with a fine needle should preferably precede to remove the pus which forms an obstacle to the rays. In suppurating cases with sinuses and skin ulceration, the pus and necrotic tissue should likewise be withdrawn beforehand, the bridges of skin separating sinus openings sometimes cut through, and iodine applied from time to time to combat superadded infection. The x rays remain, however, the main therapeutic factor. Weil divides the skin over the affected glands in as many districts as are required, so that each unit of surface treated shall receive approximately the same dose of rays. Over each area hard rays are passed through a four mm. aluminum plate, measuring eight or nine on the Benoist radiochrometre. The sittings in each region are repeated until every portal of entry has received ten, twelve, or even fourteen H units of rays. The total amount is administered in five or six consecutive days. Marked reactions with high temperature do not follow such

a procedure, except occasionally in certain soft, rapidly developing gland involvements. Neither is there ever noted a rapid growth of the lymphatic masses, or a general spread of the tuberculous process; such results as these, sometimes noted formerly, signify insufficient doses. Weil reports a number of cases, with photographic reproductions, illustrating the excellent results obtained from the use of rays in cervical adenitis.

Radium in Cancer of the Uterus.—John G. Clark (*Annals of Surgery,* November, 1916) states his views on the foregoing subject in the following words: Removal of the uterus in cases of cancer of the fundus has yielded such good results that I do not feel we are justified in taking any chances with radium, not even in the border line cases. Our attitude toward the cervical and fundal growths is diametrically opposite. In border line cases of cancer of the cervix we invariably employ radium. In advanced cases of cancer of the fundus we invariably perform a hysterectomy. A pessimistic view dominates our outlook in the surgical treatment of cervical growths if the pathological process is at all advanced, whereas fundal growths may be viewed with a cheerful optimism even when the cancerous process is extensive. As a palliative agent, we may assert with full assurance that we have never obtained results with any other method that have even approached in beneficence those secured by radium. The cloud, however, that hangs over the remedy is the danger of unbridled optimism.

Major Surgery under Minor Anesthesia.—Joseph Wiener (*Annals of Surgery,* November, 1916) sums up as to the question of performing major operations under local anesthesia thus: Are there any inherent objections to operations under local anesthesia? Surely there are: First, is the fear of causing pain. With increasing experience, with proper technic, with proper selection of cases, and by combining local with brief general anesthesia, pain will in large measure be eliminated. And even if pain were not entirely eliminated in some cases, the lessened danger of the operation, the fewer postoperative complications, the wonderful difference in postoperative comfort, would weigh heavily in favor of such procedure. That operation under local anesthesia takes more time is true; but if we figure ten or fifteen minutes to get the patient under ether, the difference in time for many operations will not be marked. Wiener has several times done a double inguinal hernia operation under local anesthesia in an hour. One objection is a real one. It is more trying for the surgeon to operate under local than under general anesthesia. There is the additional mental strain of encouraging the patient to keep quiet and to keep up his courage. The cooperation of an intelligent patient is a great help. In any case we can arrange our day's work so that not too many operations under local anesthesia are done at one sitting. Even if it is much more trying to do major operations without general anesthesia, should we not sacrifice our personal comfort for the great advantages to the patient? The answer to that question will in large measure determine the field of usefulness of this procedure at the hands of each individual surgeon.

Medical Treatment of Stenosis of the Pylorus.—E. W. Mitchel (*Ohio State Medical Journal,* November, 1916), in treating this disorder in infants does not change from mother's milk to artificial foods. In the mild cases the period of feeding is prolonged to four hours and the stomach is washed out previous to each feeding. In the severe cases from a dram to half an ounce is administered every hour or two, with lavage two or three times in the twenty-four hours. If artificial foods have to be used, they should be the first selection. Sodium bicarbonate should be added to the wash water. Normal salt solution should be given per rectum. Rectal feeding, except the giving of glucose in the five per cent. solution is of little value. To relieve pain and allay spasm opium and belladonna should be used.

Diagnosis of Ulcer of the Stomach and Duodenum.—Robert Dahl (*Hygiea,* September 30, 1916) reports forty-one cases in which the diagnosis of ulcer was verified by operation. The site varied between the lesser curvature, the pylorus, and the duodenum. The pains appeared with regularity, the same length of time after the same meal, earlier after a light repast, and later after a full meal. Sensitiveness to pressure is often present only at the time that the patient suffers the pain. Hypersecretion was present in only eight cases. In twenty-three cases there was no vomiting. Four cases had been x rayed without result as regards locating the ulcer. The author concludes that many cases of ulcer manifest themselves only by pain, but this is always more or less tardy, never immediately after meals.

Light in the Treatment of Tuberculosis.—V. Malmström (*Hygiea,* September 30, 1916) states that he has, since February, 1914, treated over a hundred cases of external and internal tuberculosis with the quicksilver quartz lamp. The patient's nude body was exposed daily for one hour to the light bath at a distance of seventy-five cm. from the lamp, the beginning dose being somewhat smaller, by shorter time and longer distance from the lamp. Paper screens covered with chalk were used as reflectors to intensify the light. The pulmonary cases were mostly in the advanced stage. After a beginning reaction in many cases, in which the sputum findings were abundant, a decided improvement occurred, the rales having uniformly diminished in number and extent, taking on a dry character; most noteworthy was the favorable effect upon the general condition of the patient. Large tuberculous glands completely disappeared or were reduced to insignificant nodules. An empyema fistula of two years' standing was healed by three and a half months' light treatment. Tuberculous affections of bones, joints, nose, pharynx, larynx, and peritoneum, as well as lupus vulgaris, were cured or much improved. The cases of external tuberculosis likewise showed a temporary reaction followed by a very marked improvement in the general as well as the local condition. The author believes that light therapeutics is destined to become a valuable adjuvant to the hygienic dietetic treatment of external and internal tuberculosis, and raises the question of its possible application in tuberculosis of the bronchial glands.

Hæmangeioma cavernosum.—William E. Lower (*Surgery, Gynecology and Obstetrics,* November, 1916) states that the usual treatment of hæmangeioma cavernosum is its complete extirpation, although Carl Beck has devised an ingenious method by which the masses of vessels are gradually transformed into connective tissue by a subcutaneous spiral ligature. "In this manner the circulation is shut off within the tumor. . . This procedure is repeated until the tumor has been diminished to the smallest possible nodule of connective tissue, and the healthy skin enlarged to the utmost. Then the hard connective masses are excised and the borders united in fine linear union. It is necessary to ligate the largest afferent vessels."

The Application of Anociassociation to Obstetrics.—Carl L. Hoag (*Surgery, Gynecology, and Obstetrics,* November, 1916) concludes as follows on this subject:

1. He wishes to emphasize that his experience, brief as it is, is in accordance with that accumulating rapidly on all sides today; that nitrous oxide-oxygen analgesia is safe to both mother and child.

2. The use of limited amounts of scopolamine during the first stage is a distinct advantage, shortening the time during which gas is required and making the analgesia more complete.

3. The work done so far has encouraged him in the belief that the injection of the perineum is a distinct help in securing relaxation of the outlet. This point gained, gas-oxygen, in experienced hands, will do as well as either chloroform or ether. The lack of any complication whatsoever resulting from the perineal injections should encourage those who feel timid about its used.

4. The combined use of scopolamine, nitrous oxide-oxygen, and local infiltration offers a practical and efficient means of conducting labor, and extends anociassociation, in its broadest sense, to the obstetrical field.

Management of Arterial Hypertension.—H. F. Stoll (*Medical Record,* Oct. 28, 1916) divides cases for treatment into two classes; those coming to the office and those confined to their homes or the hospital. The first group should be forbidden to hurry at any time, relaxation periods should be lengthened especially after the midday meal, and stairs should be ascended slowly if at all. Patients with moderate hypertension, free from morning headaches, eliminating fifty per cent. or over of phthalein in two hours should not be put on a milk diet nor forbidden meat. Meat in moderate amount once a day is desirable. The heaviest meal is best eaten at midday and supper must be simple. Several warm baths a week are advisable with a daily bowel movement, and a cathartic once or twice a week. Too active catharsis must be avoided as it may cause weakness and faintness. Vasodilator drugs are not usually indicated and often do harm, but in very high tension cases venesection may be lifesaving. Relief from sleeplessness, nervousness, and headaches by the use of potassium iodide and mercury may often be obtained even where the Wasserman is negative. The second group should be put to bed, and given digitalis, if indicated, irrespective of blood pressure. Fears of a higher tension therefrom are unfounded. Digitalis and potassium iodide often work better together than singly. A low phthalein output and an increase in blood nitrogen are found in this stage of the disease, and the diet should be low in protein and sodium chloride. If the patient is very edematous only 800 c. c. of milk should be allowed in twenty-four hours. Carefully regulated exercises should be begun when compensation returns. The distressing dyspnea in the final days can be controlled only by morphine and it should not be withheld when the end is near.

Hand Disinfection.—W. Burk (*Medizinische Klinik,* September 24, 1916), in an endeavor to find a substitute for rubber gloves, tried several substances as coatings for the hands, but each was found untrustworthy. These included solutions of celluloid, of cellulose, and of the product resulting from the interaction of phenol and formaldehyde. Each of these preparations sufficed to coat the skin with an impervious and insoluble layer without damage to the skin, but in the course of operations it was found that they all cracked about the joint flexures. From these observations, however, the author was led to test the disinfecting power of a suspension of bolus alba in acetone and found it to be extremely effective. The bolus served the useful purpose of filling up the pores and preventing the escape of the contained organisms. The technic finally adopted was to wash the hands thoroughly for five minutes with soap and warm water, to clean the finger nails, and then to apply the bolus suspension and allow it to dry. The fine powder remaining was removed with a sterile towel and the hands were ready for the operation. This technic gave results superior to those of other and more drastic methods.

Treatment of Gas Gangrene.—Franz (*Medizinische Klinik,* September 24, 1916) expresses the opinion that a considerable proportion of cases which have been cured by simple surgical antisepsis have not been cases of true gas gangrene. He supports this view by the citation of several confusing cases in which the appearance of gas in the tissues was due to the mechanical introduction of air by the missile which caused the wound, or by the growth of simple saprophytic organisms. In cases of true gas gangrene there is only one form of treatment which is reasonably successful, namely, early amputation through healthy tissues. In a few cases, seen early and showing relatively sharply localized infection, cure has resulted from multiple free incisions with excision of the affected muscle masses in their sheaths. The use of oxidizing agents and of oxygen itself gave no satisfactory results in the author's cases. In cases in which the diagnosis was doubtful it was his practice to dress the wound lightly after excision of all destroyed tissues and to make observations of the wound at intervals of a few hours, day and night. Upon the first indication of gas gangrene amputation was performed. In every case in which there was a fracture complicating the gas gangrene, amputation was performed at once. Even amputation was found to fail of cure in cases in which it had been delayed for more than twelve hours after evidence of infection had become certain.

Wounds of the Chest.—C. P. Howard (*American Journal of Medical Sciences,* November, 1916) says that the great majority of wounds of the chest received in battle, when the wounded are removed from the battlefield and eventually taken to a base hospital, need no treatment apart from absolute rest and a bland nutritious diet, as the bloody exudate usually is absorbed at the end of fourteen days after the reception of the wound. Of course, many such wounds received in battle may be fatal within a short time. Occasionally bloody fluid persists after the expiration of two weeks, and then removal by aspiration may be indicated. Less than seven per cent. of his cases ended fatally. Convalescence is slow, but the flattening of the chest almost disappears in the course of several months, and it is not uncommon to see such patients return to the firing line.

Management of Poliomyelitis.—Robert W. Lovett (*Medical Record,* Oct. 21, 1916) states that in the acute phase, from the onset to the disappearance of tenderness the treatment should consist of rest, and absence both of irritation and of meddlesome therapeutics. Splints should be used to prevent deformities while blood serum of immune patients may do good if given early. In the convalescent phase the question of muscular care and development arises when the tenderness has disappeared. Lovett considers that it is better to get the patient on his feet about two to three months after the attack. The use of braces is governed by the rule that if the patient cannot walk without them or if in walking or standing he does so in a deformed position then apparatus should be worn. With the patient up and supplied with braces, if necessary, three measures are indicated; massage, electricity, and muscle training. Massage promotes the circulation of blood and lymph, removing waste products and retarding muscular atrophy and atony. Electricity, whether faradic or galvanic, should not be relied upon too much. Muscle training is an effort to reconnect a cerebral motor impulse with a peripheral muscle contraction. It aims at two things, first at forcing the efferent impulse to develop a new path around the disordered nerve centre in the cord, and second at securing contraction of the desired muscle which is the best treatment of the muscle itself. The third or chronic stage begins about two years after the onset and here comes in the question of operative interference. Tendon transplantation should not be deferred too long, although the more destructive bone operations are better deferred to three or four years.

A Method of Augmenting the Resisting Powers of the Infected Organism.—Fernand Barbary (*Bulletin de l'Académie de médecine,* September 26, 1916) recommends, after extended trial since 1912 and lately in an auxiliary hospital in which 767 wounded soldiers and 797 other patients were treated, the induction of increased resistance to bacteria in infectious cases by injections of cholesterin and camphor. The use of camphor is based on the antitoxic and roborant power it has been shown to possess by Siebert, Lafon, and Baudet; and that of cholesterin, on the work of Chauffard, Guy-Laroche, Grigaut, and others, who credit cholesterin with antihemolytic and antitoxic properties, and have shown that the establishment of immunity is accompanied by a hypercholesterinemia, which seems to preside over the formation of antibodies. In septicemia, infectious cachexia, gangrene, paratyphoid, and tuberculous infections, Barbary found a distinct diminution of the cholesterin in the blood. He finds infection in general rapidly attenuated by injections of camphorated oil in large doses and of cholesterin. The amount of cholesterin in the blood is quickly increased, probably by excitation of the cholesterin forming function of the adrenal glands. Results clinically obtained—only four of the 767 wounded patients succumbing, and one of these through an accidental fall—lead Barbary to advise that this method be applied in all cases of dangerous wounds, both in the hours immediately following the time of injury and when operative work is to be performed. The preparation used consists of chemically pure cholesterin, 0.2 gram; camphor, 0.5 gram, and strychnine sulphate, 0.0005 gram, in five grams of olive oil, previously washed with alcohol and ster ilized. In infected wounds, one to three such ampoules are injected daily until the temperature recedes, after which one ampoule a day suffices. A series, each of ten daily injections, is subsequently given. In operative cases, one or two injections are given on the eve and on the day of operation, and later, a series of injections.

Hand Disinfection with Hypochlorites.—Dubard (*Bulletin de l'Académie de médecine,* September 26, 1916) recognizes the necessity, in a solution employed for this purpose, that it shall do no harm to the surgeon's epidermis. He now uses a solution made by dissolving 150 grams of strong chlorinated lime (one hundred chlorometric degrees) in five litres of water, then adding 180 grams of magnesium sulphate, thus converting most of the lime to magnesium hypochlorite. A little of the lime, with these proportions, remains unneutralized, but this is not sufficient to injure the skin, and has the advantage of increasing the chlorine value of the solution. In preparing for operative work, the hands are first washed with sterile water, brush, and soap, then immersed for four minutes in the solution. Next they are dried in strong alcohol, wiped with a sterile towel, and rubbed together with a little sterile oil. The final step is to prevent the hands from becoming moistened when in contact with the body tissues and secretions, thus affording additional asepsis and protection. It consists in the application of a mixture of sterile olive oil, sixty-five parts; essence of camphor, thirty parts, and oil of origanum, thyme, or mint, four parts. Ninety-eight operations, including thirty-three gastroenterostomies, were performed with this method of hand disinfection, without the least sign of infection, in spite of the fact that much septic surgery was being done at the same time without any protection for the hands other than that afforded by the procedures mentioned. Bacteriological tests showed this method to be distinctly superior to the use of tincture of iodine. No irritant action was exerted by the ungloved hand.

Treatment of Syphilis.—W. T. Wootton (*Medical Herald, October,* 1916) points out the futility of trying to bring a syphilitic under the fullest possible influence of mercury by the oral administration of the drug, and holds that the intramuscular method is little if any more effective. He further emphasizes the fact that the spirochetes invade the system very early in the infection and that treatment must be started at the earliest possible moment. His practice in all cases is to give repeated short courses of the most intensive treatment, using mercury by inunction to the point of saturation, and salvarsan by vein at five day intervals for two to six doses during the course of inunctions. Following each course there is a rest of three to six months without any form of treatment and the course is then repeated irrespective of the serological findings. Iodides are also given to meet special indications and in appropriate doses. This form of treatment must be adjusted to each individual case and it is not possible to state in advance just how much of each drug the patient will require for saturation. The treatment has given quite as good results in the author's hands in cases of tabes and syphilis of the central nervous system as has the intraspinal injection of salvarsanized serum. In such cases he advocates lumbar puncture several times during each course of treatment to promote the passage of the drugs and of antibodies into the nervous tissues. Although this method is intensive it has not caused any greater harm to the kidneys than the usual milder but more prolonged methods employed, and has given decidedly better results.

Experiments with Soldier's Foot.—Harold D. Corbusier (*Military Surgeon,* November 1916) suggests the following rules: 1. Two or more months before going to camp make a careful inspection of your feet. If there are corns, whether large, small, or soft, your shoes are not of the right shape.

2. Look for ingrowing nails and bunions, or any tender or inflamed spots.

3. Look for badly shaped toes, lapping over, hammer toes, or "claw" toes.

4. See if the arches are painful or obliterated on standing, or if the foot turns outward too much, causing the angle to roll inward.

5. If you have any of these troubles, seek treatment *at once,* from an orthopedic or a general surgeon, *not* from a chiropodist.

6. *Always* wear a broad toe shoe and one which is sufficiently long in the heel to ball measurement; also, the fit of the heel must be good, not loose, as commonly found in most broad toe civilian shoes. Obtain the camp shoe recommended by proper authority—it must be broad at the toes; thick soled, with well fitting heel; made of oiled leather; pliable throughout, especially in the sole, and without lining; the upper of sufficient height to bring it well above the ankle bones, laced with eyelets only. Wear your camp shoes at least a few hours each day before going to camp, if you have the proper shoe. This is to adjust your foot to the new shape, which is probably different from what you have been wearing.

Treatment of Phagedenic Tropical Ulcer.—Boucher (*Presse médicale,* October 5, 1916) reports good results from formaldehyde treatment in fourteen cases of phagedenic ulcer of spirillar origin. A cotton tampon dipped in forty per cent. formaldehyde solution was applied over the ulcer, causing a local necrosis. A dry bismuth dressing was thereafter applied, and renewed every week, until healing was complete. The simplicity and rapidity of action of the treatment commend it to the practitioner.

Paratyphoid Infections. — Jay D. Whitham (*Military Surgeon,* November, 1916) emphasizes certain points concerning paratyphoid infections: 1. The disease is more common than is generally supposed; many cases with typhoidal symptoms, but negative Widal reactions, being paratyphoid fever.

2. Paratyphoid infections are extremely variable in their manifestations.

3. Carriers probably play the most important role in the transmission of the disease.

4. Endemics resembling food poisoning, due to paratyphoid bacilli, must be much more common than is generally supposed. The trench diarrhea of Europe is an example.

5. The disease, though usually mild, may cause extremely severe complications, even death.

6. Considerable evidence has been submitted by competent observers to show that antityphoid vaccination does not sufficiently protect against paratyphoid infections and that a polyvalent vaccine should be used if such protection is necessary.

7. The fighting forces in Europe have suffered greatly from paratyphoid infections which, it is possible, might have been prevented had polyvalent vaccine been used.

Present Status of Röntgen Therapy.—Samuel B. Childs (*Colorado Medicine,* October, 1916), in a review of the therapeutic value of x rays, states that at least ninty-five per cent. of superficial epitheliomas without glandular involvement can be cured by the rays. Epithelioma of the lip and of the mucous surfaces is less amenable to the effects of the rays, but good results can often be obtained in cases without glandular involvement. Contrary to the common belief the results in rodent ulcer are not as good as in epithelioma. Carcinoma of the breast or uterus when inoperable should be given the benefit of x ray treatment and a number of such cases have been cured, while others have been rendered operable. The rays should always be used over a wide area after the surgical removal of carcinoma in any portion of the body. The beneficial action of x rays in inoperable carcinoma can be greatly enhanced by combining them with fulguration or other form of thermal destruction. Sarcoma responds more satisfactorily to the rays than does carcinoma and cures occur in about fifty per cent. of such cases when properly treated. Among the nonmalignant conditions amenable to the influence of x rays are acne vulgaris, acne rosacea, ringworm, psoriasis, chronic eczema, pruritus, lupus vulgaris, and keloid. Some benefit may be derived from their use also in the leucemias and Hodgkin's disease, but the acute forms of leucemia do not respond favorably.

Miscellany from Home and Foreign Journals

Perithelioma and Endothelioma of the Uterus.—W. A. Newman Dorland (*Surgery, Gynecology and Obstetrics,* November, 1916) draws the following deductions from a pathological and clinical review of these conditions: 1. Endothelial tumors of the uterus develop late in life—much later than sarcomata—the peritheliomata generally occurring at the most advanced age.

2. These growths are especially prone to occur in a preexisting neoplasm—a myoma or a fibromyoma.

3. While showing a high degree of local malignancy they but rarely give rise to metastatic deposits elsewhere.

4. It is probable that endothelial uterine tumors occur more frequently than would appear. Hence the importance of early removal of all uterine growths, which should always be subjected to a careful pathological examination.

Regeneration of Agar Culture Medium.—Philalethes Kuhn and Marzell Jost (*Münchener medizinische Wochenschrift,* September 26, 1916) state they have devised a method for the regeneration of used agar. The agar mass which is to be regenerated should be neutral in reaction, if possible, and, after it has been liquefied, eight grams of barium peroxide are added for every 1,000 c. c. Under constant stirring the mass is kept boiling until it is colorless. Then an aqueous solution of seven grams of sodium sulphate is added. This solution should be hot. Twenty grams of animal charcoal are now added to the solution and the entire mass is brought to a boil. The precipitate is allowed to form and the remainder is cleared in the customary manner with egg albumin. Before clearing, 6.5 grams peptone Witte and 6.5 grams of Liebig's meat extract are added for every 1,000 c. c.

Use of the Cochleoorbicular Reflex in the Diagnosis of Organic Deafness. — F. Gault (*Presse médicale,* September 25, 1916) states that in examining in a military hospital a large number of cases of complete, partial, or doubtful deafness, he found the ordinary subjective tests of hearing, based on the patient's own statements, often unsatisfactory, and the objective tests, consisting in determinations of the nystagmic reflex upon rotary, thermal, or galvanic excitation of the labyrinth, likewise insufficient, yielding information only concerning the vestibular apparatus and not the organ of Corti. The cochleoorbicular reflex, on the other hand, gave good results, especially in the latter. A strongly acting bicycle horn was operated at a distance of two metres from the patient by an assistant, while Gault carefully watched for contractions of the orbicularis palpebrarum of each side through a strong hand lens. The patient's opposite ear was plugged with cotton covered with petrolatum, and his sight of the horn was prevented by a suitably placed piece of cardboard or wooden board. The patient was often required to count out loud during the tests, to distract his mind from the reflex itself. In normal ears, sounding the horn was regularly followed by a marked or slight orbicular contraction, with corresponding movement of the eyelids. This implied that the cochleoacousticobulboorbicular reflex arc was open and in working order. In cases of total organic deafness following cerebrospinal meningitis or scarlatina the test was negative. In cases of complete or almost complete deafness from war traumatism, generally labelled "deafness from concussion of the labyrinth," some slight orbicular contraction was usually noticed, and often upon explaining the test and its result to the patient and referring to a mere "torpid condition" of the auditory nerve, surprisingly rapid improvement in hearing was obtained—which leads Gault to consider most of these cases as instances of cortical deafness by inhibition rather than of labyrinthine concussion. In some cases of partial deafness through middle ear disease, the cochleopalpebral reflex, after the subjective tests have been made, permit of a prompt conclusion as to the exact amount of hearing remaining, and of rapidly overcoming any voluntary or subconscious exaggeration of the deafness by the patient. In the case of malingerers, fraudulent claims of total deafness are promptly eliminated.

Spontaneous Liberation of Epinephrine from the Adrenals.—G. N. Stewart and J. M. Rogoff (*Journal of Pharmacology and Experimental Therapeutics,* September, 1916) report an experimental study on the spontaneous liberation of epinephrine in the cat by means of action on the denervated iris and on the blood pressure in the same animal, when blood from the adrenals is permitted to pass into the circulation from a pocket of the vena cava in which it has been artificially collected. The amount of epinephrine spontaneously liberated in cats varied in different experiments from 0.0003 to 0.001 gram a minute for each kgm. of animal. After section of both sympathetic trunks in the thorax near the diaphragm, including the major splanchnics, this spontaneous liberation of epinephrine was completely abolished. No increase in epinephrine liberation was detected when sensory nerves were stimulated.

The Recent Epidemic of Grippe.—Joseph A. Capps and A. M. Moody (*Journal A. M. A.*, November 4, 1916), in reporting a study of a large group of cases occurring during the epidemic of last winter, show that the disease varied from a very mild "cold" to a severe illness. In the majority of patients a leucocytosis was present, ranging from slightly hypernormal to 15,000. Pneumonia was a frequent complication of the disease. A study of the bacteriology in a large number of cases revealed a predominance of the streptococcus and pneumococcus in various portions of the country, with only extremely rare occurrence of the influenza bacillus. The question was thereby raised as to whether the so called influenza bacillus really had anything to do with the epidemic, and in connection therewith it was interesting to find that the records of the great pandemic of grippe of 1889-1890 showed a similar great preponderance of the streptococcus and pneumococcus.

Myasthenia gravis with Thymoma.—W. A. Jones (*Journal A. M. A.*, November 4, 1916) reports a case of this uncommon condition occurring in an adult otherwise apparently well. In this patient at necropsy there was found a smooth, soft, encapsulated thymic tumor which consisted of fetal thymic tissue. The literature of myasthenia gravis showed seventeen instances of persistence of the thymus and ten of thymic tumor in a total of fifty-six necropsies. All of the tumors were benign except one. It would seem that the presence of thymic tissue was closely related to the occurrence of myasthenia gravis.

X Ray Diagnosis of Tumors of the Large Intestine.—H. Schlecht (*Medizinische Klinik*, September 24, 1916) states that in a considerable proportion of cases of tumors of the large intestine diagnosis by means of the x ray and bismuth or barium meal is an easy matter, but there is a small proportion of cases in which the passage of the meal is not obstructed or may even be abnormally rapid, and in which there are no shadows suggestive of neoplasm. In these cases the diagnosis may be rendered easy by the use of a bismuth or barium enema, and the x ray observation of its course. Where a tumor is present there will usually be an obstruction to the passage of the enema at the site of the growth with overfilling and dilatation of the distal portion of the large intestines and the desire to expel the enema. The occurrence of these three symptoms is very characteristic of tumors of the large intestine, so much so, in fact, as to be almost pathognomonic of their presence. If they are combined with the passage of blood, either occult or gross, a malignant neoplasm is almost certainly present.

Multiple Myelomata.—B. M. Vance (*American Journal of Medical Sciences*, November, 1916) reports a case of this nature, with special attention to the pathological findings at autopsy, and studies their relationship to the diseases of the lymphatic hematopoietic system. He concludes that multiple myelomata are multiple primary tumors of the bone marrow, which occur mainly in elderly persons, and are manifested during life by deep seated pain in the bones, characteristic deformities of the skeleton, spontaneous fractures in many bones of the body, severe secondary anemia, and emaciation. The presence of Bence-Jones protein in the urine is characteristic of many cases, but is not a pathognomonic sign of the disease, as it is occasionally found in the urine of other bone conditions. At post mortem cases of multiple myelomata show the presence of soft, homogeneous tumor masses which replace the cancellous tissue of the bones of the trunk, vertebræ, ribs, and sternum, and less often of the ends of the long bones of the extremities, the diplœ of the skull, and the small bones of the hands and feet. The multiple myelomata are confined to the bones, though a few cases have been reported of extraskeletal growths. The multiple myelomata are composed of cells practically identical with the myeloblasts of the bone marrow or their derivatives. Five different groups have been described: Myeloblastoma, neutrophile myeloma, erythroblastoma, lymphocytoma, and plasmocytoma. The first three are true multiple myelomata. The lymphocytoma is a distinct tumor type, but as there is considerable doubt regarding the relation of the tumor cell to the myeloblast, it cannot be unquestionably classified as a true myeloma. The plasma cell tumor cannot be considered as a pathological entity until more is known about the origin and mode of development of the plasma cell. Multiple myelomata belong to that group of tumors which are composed of cells derived from the primary mesenchymal wandering cells, and are closely related to the leucemias, chloromas, and other diseases of the lymphatic hematopoietic apparatus.

Use of Carbonic Acid Powder in Treatment of Vaginal Conditions.—Felix Mendel (*Münchener medizinische Wochenschrift*, September 26, 1916) recommends the use of carbonic acid powder prepared from sterile, chemically pure carbonate of sodium in the treatment of vaginal conditions. This powder when blown into the vagina by means of a bellows gives off nascent carbonic acid which has great bactericidal power. Instead of acting as an irritant as most other powders used for this purpose do, it acts as an anesthetic. It also has an antiphlogistic action. Thick discharges are rendered more fluid and are expelled more easily, and secretions are diminished. The treatment is given one to three times daily. The patient may carry out the treatment herself, either in the erect or the recumbent position. No douches are necessary with this method of treatment. The treatment is of far greater value than other forms—such as irrigations or tamponing.

Spasdomic Stricture of the Rectum.—L. J. Krouse (*Lancet-Clinic*, October 28, 1916) asserts that spasmodic rectal stenosis, though frequently held to be imaginary by writers, is really a clinical entity. It is uncommon and of but short duration, but while it lasts it interferes with free passage of the feces. It is easily detected by digital exploration, the rectum imparting that peculiar sensation felt when the finger is grasped by the circular muscle fibres. Relaxation soon occurring, the finger is then introduced up the bowel, but recurrence of the spasm can be repeatedly induced by simply irritating the affected area. The spasm is usually situated about one and a half to two inches above the anus. Krouse believes the lower Houston valve to be the part usually involved. The condition is not a disease *per se*, but a symptom of some rectal disease, or occurs reflexly through disease in one of the adjacent organs. A rectal ulcer is the most important factor. Whatever be the cause, its removal brings about a cure. Krouse agrees with those writers who believe that spasmodic stenosis may be a forerunner of organic rectal stricture, but holds that such a sequence of events is practically limited to cases in which the exciting cause is rectal inflammation in the vicinity of a valve. Curing a rectal ulcer causing stenosis in its early stage will lessen the chances of a subsequent fibrous stenosis. The author reports two cases of spasmodic stenosis, and one of annular fibrous stricture, with an ulcer below which is believed to have been responsible for the stricture.

Obscure Fever in Infancy.—Edgar P. Copeland (*Journal A. M. A.*, November 4, 1916) states that many cases of fever of obscure origin are encountered in infancy and early childhood, and seeks to point out the possible causes for some of these occurrences. One of the commonest forms is that associated with nervous instability, and apparently due to an abnormal response of the organism to ordinary conditions. These cases are very irregular, have nothing in common except the occurrence of fever without demonstrable cause, and occur in neurotic individuals. They are particularly common in rhachitic children, and in those with tendency to laryngismus stridulus or tetany. Among the more definite, but little recognized causes of obscure fever the author has observed dental caries, obscure forms of otitis media which are often recognizable only by the discovery of a drop of pus oozing from the mouth of the eustachian tube, and deep inflammation of the tonsil.

Typhus Fever.—H. da Rocha-Lima (*Münchener medizinische Wochenschrift,* September 26, 1916), as a result of experimental work, concludes that lice are very seldom carriers of typhus infection beyond the first generation. In only one instance in thirteen did the second generation prove to be capable of carrying infection. Lice cannot be infected from the bodies of convalescents. Because of this fact there are no healthy typhus carriers comparable to diphtheria or typhoid carriers. The virus is so sparingly present in the blood during and after the defervescence of the fever that, as a rule, lice cannot become infected during this period. In order to become infected it is only necessary for the louse to bite a typhus patient a single time. Lice which suck the blood of a patient on the fourth day of his disease will show the polar staining bodies described by Ricketts and Prowacek. Whether this is also true during the first three days of the disease has not been determined. The virus can be demonstrated to be present as early as the fourth day following the sucking of the blood either microscopically or by animal experimentation. For animal experimentation guinea-pigs are as valuable as monkeys.

Retroperitoneal Rupture of the Duodenum by Blunt Force.—Robert Talbott Miller (*Annals of Surgery,* November, 1916) concludes with regard to this accident as follows: 1. Subcutaneous rupture of the duodenum forms ten per cent. or more of the total number of subcutaneous ruptures of the bowel.

2. About one third of the subcutaneous ruptures of the duodenum occur in its retroperitoneal portion and do not communicate with the peritoneal cavity, as a result of the primary injury.

3. In one third of the reported cases, the lesion was not recognized at operation, though operation was undertaken on a diagnosis of probable rupture of the bowel. In contrast to this stands the fact that the findings at operation are distinct and practically pathognomonic.

4. The presence of a retroperitoneal hemorrhagic extravasation, occupying the root of the transverse mesocolon and more or less of the adjacent region, with a peritoneal cavity which is macroscopically clean, is practically pathognomonic of traumatic retroperitoneal rupture of the duodenum, and with the presence of subperitoneal petechial hemorrhages and fat necroses over the ascending colon, transverse colon and mesocolon, presents a typical picture.

5. There is a mortality of ninety per cent. or more in this group of cases, contrasted with an estimated mortality of seventy per cent. in subcutaneous rupture of the bowel in general.

6. The symptoms of such a rupture differ from those of intraperitoneal rupture very slightly except that the onset of severe urgent symptoms is somewhat slower.

7. In the fatal cases, extensive retroperitoneal extravasation is constant, and together with the effects of duodenal fistula and duodenal toxemia is, in part, responsible for the high mortality rate.

Intestinal Parasites in Foreign Students.—Edward J. Van Liebe (*Journal A. M. A.*, November 4, 1916) states that it is well known that intestinal parasites are very common among the Chinese and Japanese, and it has been found that a very large proportion of the Japanese of the working classes in San Francisco harbored one or another parasite. The present study was undertaken to discover the prevalence of such parasites among the higher classes of foreigners, and includes the examination of twenty foreign students. In the stools of ten of these, intestinal parasites were found. The commonest parasite was the ascaris, but hookworm, Trichocephalus dispar, Hymenolepis nana, and Schistosoma japonicum were also found. These findings indicate that there is some danger of infection from the average foreign student coming from a country in which intestinal parasites are common.

Smoke and Powder Gases in Naval Warfare.—D. N. Carpenter (*Military Surgeon,* November, 1916) summarizes the results of investigation of this question as follows: 1. That there is danger to the personnel from the powder gases in naval action from the enemy's explosive shells. This danger is greater in closed gun compartments than in turrets, and the gases may be distributed to all parts of the ship through the ventilating system. Owing to the positive internal pressure in the turrets and the gas ejectors on the guns there is no contamination of the turret air from our own gun fire.

2. Owing to the possibility of fires being started from shell impact and explosion, there is a danger from smoke gases.

3. Perforated funnels, ventilators, etc., may cause smoke contamination of any part of the ship with serious effect on the personnel.

4. The fireroom force is not only exposed to the gases from powder and smoke received through ventilating conduits, but it is possible that there may be some contamination from the furnace fires and coal bunkers.

5. To prepare for this danger it will be advisable: To provide a liberal supply of a simple type of respirator to be used in gun compartments, handling rooms, fire and engine rooms, turrets, etc.; to provide suitable helmets for the repair party to fight fires; to provide additional electric fans and blowers in closed gun compartments to be used in emergencies; and to provide oxygen cylinders.

Proceedings of National and Local Societies

AMERICAN LARYNGOLOGICAL ASSOCIATION.

Thirty-eighth Annual Congress Held at Washington, D. C., May 9, 10, and 11, 1916.

The President, Dr. G. Hudson-Makuen, in the Chair.

(*Continued from page 973.*)

A Résumé of One Year's Work with Suspension Laryngoscopy.—Dr. Robert Clyde Lynch, of New Orleans, said that, to prevent fracture of the alveolus, he placed a strap under the occiput and clamped it into the angles of the pear shaped ring, thus relieving the pressure of the tooth plates against the teeth. In order to prevent other tooth injuries, he used dental impression spoons filled with moulding compound which offered complete protection to the teeth, facilitated the introduction of the spatula, and made it easier to keep the spatula in the middle line. He also described the table, which could be raised twenty inches, the top tilted and moved in a circle. There were foot and shoulder braces. Regarding intrinsic epithelioma of the larynx, his experience had been exceptionally good with endolaryngeal removal, but he felt that his experience was not large enough to reach definite conclusions. Dissection under suspension was not difficult, and could be done without permitting an instrument to touch the tumor mass. Nineteen cases of papilloma had been successfully operated on, dissecting well below the base, curetting, and painting with alcohol. Pedunculated fibroma, vocal nodules, a cyst of the arytenoepiglottic fold, pachydermic laryngitis, perichondritis of the thyroid, fracture of the thyroid cartilage, tuberculous laryngitis, abscess of the epiglottis, and foreign bodies in the trachea and esophagus were all cared for by means of the suspension apparatus.

Dr. Emil Mayer, of New York, remarked that there was one phase of suspension that had not been mentioned by the writer of the paper, which had worked splendidly in his hands, and that was in the treatment of stenosis of the larynx and trachea. In one instance, that of a little boy who was on his service at Mt. Sinai Hospital, and who had tracheal stenosis, postoperative, it became necessary to intubate, and the only way possible was under general anesthesia. It was his hope that they could keep the trachea widely open with the wearing of the intubation tube. With the capable assistance of his associate, Doctor Yankauer, this boy had been anesthetized, and they intubated a number of times. He had been wearing the intubation tube for a matter of two years now, and they were in hopes that he would be able to do away with it eventually by the interesting method of transplanting fascia in cicatricial tissue. In this case he did not know what he would have done without being able to put the child under general anesthesia and use the suspension apparatus; first of all, to distend the web of cicatricial tissue, and then to intubate.

The second case was that of a man with syphilitic stenosis of the larynx. It became necessary to do a tracheotomy on account of the stenosis. He then received regularly, about three times a week, a distention of his larynx by means of Schrolter's tubes of increasing diameters, so that by the time he was ready for the intubation tube, his larynx was fairly well distended. He also received some salvarsan injections. The speaker felt that they were able to do something for him in a good deal quicker time than ever before. The man was given a hypodermic of morphine and told what they wanted to do, and without any general anesthesia whatever they put in the intubation tube. This remained *in situ*, and about ten days afterward he coughed out the tube. The amount of breathing room was so much greater directly after this that they were willing to do without the intubation tube. In this exceedingly short space of time, by this means and the treatment of salvarsan and mercurial injections, he had been almost cured. The suspension apparatus helped them materially in this case.

Dr. Robert Levy, of Denver, observed that in the treatment of tuberculosis of the larynx he had been pleased with the apparatus in removal of the epiglottis; the special feature in its favor here was that they had perfect control of the hemorrhage following the excision of the epiglottis. Before the advent of the suspension apparatus, in an attempt to remove the epiglottis, he had rather serious hemorrhage upon two occasions. In several cases of epiglottectomy since the suspension work had been in vogue, hemorrhage had had no terrors whatever for him. He had seen an artery spurt from both sides of the stump, of sufficient size to be easily seen by a class of students at some distance from the operation. The artery spurted into the mouth, and they controlled the hemorrhage with the greatest ease by means of artery forceps. In curettage or cauterization of the larynx for tuberculosis the apparatus was of great value because they could do so much more in one sitting than by the direct method. With these cases it had been his practice to use scopolamine and morphine, although in one case he had a death on the table, which he attributed to the highly unstandardized preparation of scopolamine. Tumors of the larynx had been exceptionally easy of removal with this method. This fairly sized malignant tumor was removed by suspension. It sprang from the posterior wall of the larynx and came over by its attachment on the external surface, so that it was partially extrinsic. It was placed in such a position that when the patient sat erect it flopped into the larynx and produced dyspnea. On two occasions the patient was picked up on the street and sent to the hospital, so that any prolonged operation by direct method would have been impossible, but by suspension it was removed with the greatest ease

In the dissection of a venous cyst with large veins that bled freely into thehypopharynx.the method was particularly valuable, because he could make a wide dissection. This case was one in which removal had been attempted on several occasions without success. He made two attempts, a cautery had been used several times, and one consultant injected it with iodine.

It recurred always until they were able to make a wide opening under suspension.

Dr. Harris P. Mosher, of Boston, when Doctor Lynch began his work, especially the work of removing malignant disease of the larynx, withheld his judgment for a time, waiting to see what his results would be. In the paper read this morning he was pleased to see that he had gone on carefully with a great deal of judgment, and that he had come to the conclusion which many felt that he would come to—that is, that the removal of malignant disease by suspension was not a final success, but that thyrotomy was better. For himself, he felt that he much preferred thyrotomy to suspension removal in malignant disease.

Dr. Robert Clyde Lynch, of New Orleans, considered that the chief essential of the suspension apparatus was to obtain relaxation of the parts. Whether the anesthetic was morphine and scopolamine or another, was left to the individual judgment in each case. He had used only cocaine anesthesia, and preferred it. He gave one or two doses of morphine, one fourth grain one or one and a half hour before the operation, and one eighth grain one half hour before the operation was to be done. For surgical work, he much preferred general anesthesia in cases where it was not definitely contraindicated. Under general anesthesia they got the proper amount of relaxation of the parts, and were able then to suspend the patient until they got the proper view. They must understand, suspension was not an easy proposition so far as the patient was concerned. It was not painless, and for that reason patients must be put in shape that would not interfere with the work after it had once been started.

Pathogenesis of the Nasal Neuroses.—Dr. Charles P. Grayson, of Philadelphia, reintroduced the subject because of the fact that during the past few years some very important additions had been made to their knowledge of the causes and consequences of certain disturbances of metabolism, the effects of which should arouse particular interest because of their bearing upon the genesis of the nasal neuroses; namely those that were exerted upon the cerebrospinal and sympathetic nervous systems. Reference was intended only to the vasomotor and secretomotor neuroses of the nose, and not to the functional disorders of the olfactory nerve, nor the neuralgias, of intranasal or accessory sinus origin. The treatment of these affections had not been rational, in the sense of having been directed against their cause rather than their effects. It had been too largely local. Loss of vasomotor equilibrium was almost invariably due to a greater or less degree of nervous exhaustion. Anaphylactic reaction might explain a moderate number of cases. The basic condition of almost all of these patients was one of neurasthenia due to metabolic derangement occasioned by persistent violation of the laws of personal hygiene. The studies of Abderhalden, Fanser, Kafka, and others, of the physics and chemistry of the colloids and of the effects of ferments, toxins, and hormones upon the sympathetic nervous system had a close relation to the etiology of the nasal neuroses. No strict pathogenic analogy existed between these diseases and the angioneuroses of the nose, but it required no great stretch of the imagination to discern a possible or even probable relationship between the metabolic processes concerned in each. It was almost a certainty that in dealing with the nasal neuroses they were dealing with phenomena that were the outcome of some perversion of metabolism. Its exact nature might vary in different cases, involving at times some glandular dysfunction, at others toxemias of intestinal origin, and at still others the presence in the blood plasma of certain ferments or hormones, but in all cases the symptomatic result was due to the same intermediate cause—a toxic action which expressed itself through the sympathetic or autonomic nervous system. To be successful in suppressing the neurotic type of nasal disorder, they must abandon their fruitless search for specific remedies and apply themselves to the hygienic instruction of their patients and to the development of an internal treatment founded upon a recognition of the essential nature of the disease.

Dr. Greenfield Sluder, of St. Louis, averred that the entire text of Doctor Grayson's paper was so at variance with the work he had done, beginning in 1909, that he felt impelled to recall some of the things that were within this discussion. He realized then, and did now, that there were many elements, all of which Doctor Grayson had cited, which must be considered. Patients were sometimes highly neurotic and neurasthenic, and all of the various features he had mentioned were there, but if they traced some of these patients back to the beginning of their symptoms they would find that up to a certain time they were in good health and supposed to be normal; that they began with a violent coryza, with a terrific headache, and in the wake of that there followed pain in the neck, chest, etc., conceived by the neurologist to be pathognomonic of neurasthenia. The pain in their necks and stiff necks was transferred to a "dislocated vertebra," and for twenty years they were spoken of as neurasthenic. Watching these cases from time to time, it had been his opportunity to make out that preceding these symptoms was a sphenoidal postempyema, and in the wake of that remained a subacute inflammation, sometimes localized sharply to the sphenoid palatine formation or the membrane which overlay the nasal ganglion. The membrane overlying the nasal ganglion was a sharply inflamed patch of redness, clear as one of the lamps on the wall, and an application of cocaine to that particular point would relieve all the symptoms—the pain in the neck would vanish, the eyes become normal, etc. It seemed very difficult to work out that such a case in an able bodied normal man, hard worked and responsible in life in every way, should point to the fact that the subject had suddenly become neurotic. He would not say anything more about it other than that his observations were in direct diametric variance with those of Doctor Grayson.

Dr. Burt R. Shurly, of Detroit, thought that they all erred in taking care of this class of cases because of the fact that they did not classify them where they properly belonged. In his opinion these cases should at least come under three large classifications: 1, Cases which were sensitized to some particular condition, a food sensitization perhaps; 2,

a so called pollen sensitization; 3, a sensitization to some other chemical substance.

They were just beginning to understand a few of the phenomena which might give rise to these devious motor disturbances. When they carried this subject deeper and farther, he thought that these three classifications would include cases which Doctor Sluder had mentioned, where they had termination in a purely localized condition; again, where they had a sensitization; and still again, where they had what had been so beautifully demonstrated in the laboratory with the carrier pigeon—a condition of early nerve fatigue in the granules in the giant cells of the spinal cord. They could take a carrier pigeon that had been on a long flight and examine histologically the giant cells of the spinal cord and find it completely changed from the picture of another pigeon's cells histologically. The granules in the first pigeon were absolutely used up, and the whole problem of nerve fatigue following that long flight of the carrier piegon could be absolutely seen under the microscope. It was very remarkable—the change which the nerve cells showed. It would, therefore, seem very easy for that class of neurasthenics whose vasomotor function was less under hereditary disability, to have nerve fatigue develop under the slightest exercise. It seemed to him that they must be very much broader in their consideration of this subject.

Dr. George A. Leland, of Boston, believed for a long time that they had an autointoxication in these cases. Why were some patients so highly susceptible to nascent proteins? Was it not because they were so hypersensitive to all proteins? That meant that they were overfed in a nitrogenous way. If a patient was highly sensitized to nitrogen, if he had autointoxication from hyperacidity of his blood, shown by the hyperacidity of the urine, then it was reasonable to suppose that a nascent protein in its most harmful state coming from a germ of pollen should set up these nasal neuroses. He did not consider it altogether a case of neurasthenia, but the last straw broke the camel's back. The patient was hypersensitized and therefore affected by these proteins.

He cited a case of a fashionable young lady, about thirty years of age, who came into his office one day, very indignant because she had been treated for a long time in various ways without obtaining relief. So he asked about her general condition, and in the course of the questioning it developed that previous to four years before she saw him, she had been a stenographer, living very simply in a cheap boarding house and taking a normal amount of exercise each day. For the past four years she had been married to a wealthy man, and since that time had been living at a fashionable hotel in Boston, eating heavy and rich foods, drinking regularly, and not exercising at all. When she had finished the story he told her, "Back to the simple life for yours!" and put her on a proper diet, and in less than three months she had no more hay fever and had had no more since.

Dr. Lewis A. Coffin, of New York, had had some satisfaction in his treatment of this class of cases, which had been direct general treatment of the patient, particularly in regard to diet, elimination and cleaning up of the bowel.

Dr. J. S. Solis Cohen, of Philadelphia, had enjoyed the paper under discussion, because it confirmed the opinion he expressed more than a generation ago in one word—"coddling."

Dr. Joseph L. Goodale, of Boston, thought there was undoubtedly a psychic effect in some forms of this condition. They knew that the outbreak of hay fever in certain cases frequently occurred on exactly the same day every year, notwithstanding the great seasonal variations and the fact that the pollen did not appear always on the first of August. There were certain cases in which the hay fever appeared on the first of August regularly, and that was the result of a psychic expectancy. The man who went into the barn to set the broken leg of his friend was not thinking about his hay fever, and that was another reason why it probably did not develop. His mind was not fixed upon the fact that he might develop hay fever.

Dr. Charles P. Grayson, of Philadelphia, did not intend to teach anything new in his paper. His only intention was to refer to and emphasize certain facts of comparatively recent discovery or elaboration. He thought Doctor Shurly's classification of these different cases was a thing they ought to be particularly cognizant of in every new case they examined. There was no question of the occurrence and existence of cases such as those referred to by Doctor Sluder, but they were in a class by themselves. If he meant to imply that it was a very large and extensive class, he had his doubts. Of course, there were a great many in the aggregate, but the proportion to all others was comparatively small.

Sarcoma of the Nose—Report of a Fatal Case, with Metastases in the Cervical Glands and in the Brain.—Dr. J. Payson Clark, of Boston, told how a female, sixty-four years old, noticed a swelling on the nose for four months. When first seen it was about the size of a small marble. For a month there had been a slight bloody discharge from the nose. There was a dark purplish tumor visible on the outer wall of the left nostril just above the vestibule. The growth was completely removed. The microscopic diagnosis was either carcinoma or sarcoma. In two months a gland was felt under the left side of the jaw. This was excised and proved to be a spindle cell sarcoma, thus determining the nature of the original growth. Seven weeks later a gland was palpable under the left sternomastoid muscle. Coley treatment was tried, without apparent success, for two months. At the end of this time a small recurrence was found in the nose and removed, and a month later a complete glandular dissection of the left side of the neck was successfully performed. Three weeks later, the patient had mental symptoms, incoherent talk, convulsive attacks, motor aphasia, and dysphagia. At times she was very drowsy, and then restless and irritable. She soon lost power of locomotion and control of sphincters. She became very comatose and hard to rouse, and ate practically nothing for the last ten days of life. An autopsy showed three metastases in the brain. The most interesting features of this

case were the metastases in the brain and cervical glands. The speaker could find but eight reported cases of sarcoma of the nose in which metastases were said to have occurred. Six of these cases were somewhat doubtful, leaving only two (beside the case here reported) in which metastases occurred in the cervical glands, and only one other case in which they occurred in the brain.

Dr. Robert C. Myles, of New York, found the question of sarcoma of the nose and accessory sinuses an interesting one because of his optimistic feeling with regard to it. A few years ago he had two cases of sarcoma in the frontal sinuses, and by a complete operation removing the bone extensively and all the periosteum he was able to get a good result. One of the cases had invaded the orbit. It was now more than seven years ago and neither of them had recurred. Twelve to fifteen years ago he reported a case where the whole of the nose was involved, in which everything was removed very deeply, without recurrence.

About two years ago he had a case of extensive carcinoma, which first appeared to be sarcoma, involving the external wall and ethmoid, in which everything was removed—the antrum freely taken away with extensive removal of the periosteum. That patient had had no recurrence, and since that time had developed remarkably physically and in every way. So that he did not know what it was that caused such dread of these cases. Personally, he thought the good results must be something more in relation to the periosteum than to the bone. If that was thoroughly removed, even if they had to leave the bone, as they did especially when one of the orbital plates was involved, there was still a lot of hope. They ought not to let these cases go on. He remembered the case of a woman who had sarcoma of the septum, and because they did not remove her septum to the cribriform plate, she died of metastases in the brain. With that idea of conservatism they did not remove the whole septum, and he thought it was a mistake.

Dr. J. Payson Clark, of Boston, said they had all seen a great many cases of sarcoma which had become well after thorough removal, but in this case he felt that there was no question that the glands of the neck and metastases in the brain had already occurred before he operated. He was led to that view from the fact that, apart from the slight recurrence in the nose, there was nothing to suggest the probability of extension of the growth. This was not a direct extension of the growth to the brain, but the growth was carried through the lymphatics.

Brain Abscess from Chronic Suppuration of the Frontal Sinus.—Dr. T. Passmore Berens, of New York, reported a case, of a male, aged thirty years, who was operated on, January 16, 1913, under gas-ether anesthesia, by a radical external frontal and sphenoidal operation and opening of the antrum of Highmore through the nasoantral wall. Convalescence was slow. In December, 1913, pus in the nose. Old wound reopened through the nose and washed out. This had to be repeated in July of the following year. In December of the next year recurrence of discharge, and on January 5, 1916, there was a large swelling of the cicatrix in the right frontal region and headache, and the old wound was opened under anesthesia. Much pus flowed from the wound, and also from the antrum, which was opened. Granulations in the roof of the sinus hid a perforation which led to a cavity two and one eighth inches from the roof of the sinus. This opening was gently enlarged, and a horse hair drain placed therein. Finally, a soft rubber drain was inserted, and the discharge continued for five weeks. The wound was not allowed to heal for some weeks thereafter. Culture from brain showed Streptococcus hæmolyticus in pure culture, and the same was found in blood culture in small numbers the day after the operation. Recovery complete, except that there was still considerable discharge of pus from the left nostril.

Operations on Tonsils and Adenoids in Diphtheria Carriers.—Dr. Thomas Hubbard, of Toledo, said that local treatment was very unsatisfactory, as most of these patients had enlarged tonsils and adenoids, and crypts could not be reached by antiseptic applications. However, it should be added that certain cases must be treated in this manner until in condition for the radical surgical method, and occasionally it would be successful. Thorough tonsillectomy and adenoidectomy were proving very efficient in cleaning up carriers. Operations—that is, tonsillectomy and adenoidectomy—could be undertaken with confidence that the person was perfectly immune. In spite of the fact that false membranes appeared in tonsillar fossæ, these patients recovered in a reasonable time. It must be borne in mind that the immunity was not certain. Each case must be studied carefully. The immunity test of Schick, made before the time of operation, would aid decision. In all of these cases exhibiting transient immunity the question of antitoxin naturally came up. Anaphylaxis must be taken into consideration, tests of sensitization, etc., and all precautions taken in administration of serum at such intervals. The physical condition, together with the skin reaction tests, should decide whether or not the patient was in condition for operation.

Dr. Stanton Friedberg recalled that this problem of carriers was called to their attention several years ago by the fact that they had patients who, on account of having positive cultures in their throats, were compelled to remain in the hospital for weeks, sometimes fifty to sixty days. As they had only a limited capacity (thirty to forty beds), this was a serious problem, for here they had clinically well patients occupying beds which were needed for others. They experimented along various medical lines without any particular effect in some of the cases, and it was then that nasal complications occurred. In spite of all the local treatment they found that there were a number of cases that would not clear up, but had to remain in the hospital forty or fifty days. In these cases he would urge nasal cultures as well as pharyngeal, for they frequently found that they had positive nasal cultures when there were no positive pharyngeal cultures.

A certain class of these cases would clear up under medicinal treatment. They had tried out vaccines without particular effect. The feasibility of medical treatment in some of these cases they could illustrate in this way: They knew that they found the bacilli in the depths of the crypt, where it was

impossible to reach the condition. It was here also discovered in the epithelium, and that perhaps explained why they did not get any effect from local applications of medicine.

As to those cases which involved the nasopharynx and the nasal accessory sinuses, as Doctor Hubbard had mentioned, the accessory sinus cases were the hardest ones to deal with. To illustrate the futility of the use of the staphylococcus spray, he would cite a case in which they were deterred from using this method—a case where meningitis followed its use.

In the case of a child between two and three years of age, who had nasal discharge, a mixed infection, staphylococcus unilateral with diphtheria bacilli constant, there were repeated cultures which were always positive. The house physician looked into the nose and found a shoe button which was keeping up the local infection, and upon removing the shoe button it cleared up immediately. They had had other cases where the culture removed remained positive in chronic rhinitis, which might possibly have been some ethmoid involvement. There were a number of points which might be brought out that were most interesting. One condition which they ought to consider was the occurrence of the postdiphtheritic paralyses. He did not know whether any work had been done in these cases or not. There was a question in his mind as to whether or not the constant harboring by the tonsil of toxins thrown out continually did not produce these paralyses. It would be interesting to investigate peripheral neuritis. He would like to do it if he got the cases, for he thought it would be an interesting fact to determine. They had made it a practice to give medication a thorough trial. They took the Schick skin reaction, operating only in six cases in which the reaction was negative. They had not used anything after operation. They had taken the nasal cultures and other cultures afterward, so that their results would not be influenced by any application made to the throat. It was common in large hospitals for cultures to be taken after an application to the throat, and in the event of securing three negative results to let the patient go out. They determined to eliminate that factor entirely. The results after operation had not differed in any respect from those seen ordinarily. He reported several months ago six cases in which they had removed the tonsils and adenoids, where the results were startling. The next day after operation, without any application at all, the cases cleared up. They took cultures for five days afterward, and each time they were negative, except in one case, in which the nasal cultures remained positive. The whole question was very important, and a simple reference to the literature would show a gradual wave in the curve of the amount of work contributed to the study of carriers in recent years.

Dr. Robert Clyde Lynch, of New Orleans, said his experience in this direction covered twelve or fourteen cases, and there were a few points he would like to bring to their notice. First of all, there were twenty or more varieties of pseudopathic bacilli in which the microscopist appeared almost unable to absolutely and faultlessly tell the difference between the true organism and the pseudo variety. He thought this was important, for frequently they might be dealing with a pseudo variety. The second point was in relation to a little matter of technic in the administration of antitoxin in patients who had been previously sensitized by the administration of horse serum. The patient was given a small dose just above the ankle, and there was a constrictor ready for application above the knee; three or four drops were injected just under the skin above the ankle, and the constrictor ready. Sufficient time was allowed for the development of the anaphylactic symptoms, and if they did not develop in one half to three quarters of an hour, the injection could be made. If they should develop, the constrictor was applied.

He would like to report a case of a medical student who had rather a virulent attack of diphtheria, which yielded to twenty thousand units of antitoxin. The patient gradually got well and finally had two negative cultures, with a normal temperature four days, and was ready for discharge. Suddenly there was a rise of temperature to 99° F. and the appearance on the surface of the tonsil of acute follicular inflammation, which gave a culture of probable diphtheria. This was fourteen days after the first injection of antitoxin. They proceeded again to give him 20,000 units, and he was discharged. Six weeks later he came walking in on crutches, just able to get about, with paralysis of the soft palate and extensor muscles of the extremities, and suffering from constipation, which he had never had before. This man's cultures were taken and shown to be positive from the tonsils. He was treated locally without result. Tonsillectomy was done, and in two weeks after the tonsillectomy the paralysis entirely disappeared without further medication.

(*To be continued.*)

Letters to the Editors

A BRIEF PRELIMINARY REPORT OF THE EFFECT OF SEXUAL SECRETIONS WHEN ABSORBED BY THE OPPOSITE SEX.

New York, *November 11, 1916.*

To the Editors:

Below is a brief preliminary report of some extremely interesting and valuable tests I have been conducting during the past few years. I have talked this subject over with so many physicians that I believe it is well at this time to send in a brief report of this nature to forestall claims from other sources. On these simple tests I have amassed some valuable information, that I will publish shortly.

When the male sexual secretions obtained at the height of the orgasm are passed through a Berkefeld filter and the filtrate injected subcutaneously into a female or otherwise absorbed into her body tissues, they greatly stimulate sexual desire.

When the female sexual secretions obtained at the height of the orgasm are passed through a Berkefeld filter and the filtrate injected subcutaneously into a male, they act as a powerful aphrodisiac. These tests have been carried out on human subjects.

After coition both the male and female are profoundly stimulated sexually by absorbing the secretions from the opposite sex, hence there is a desire for a quick renewal. This is one of Nature's safeguards in propagating the species.

Charles H. Duncan, M. D.

Book Reviews

[We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.]

Nerve Injuries and Shock. By Wilfred Harris, M. D. (Cantab), F. R. C. P. (Lond.), Physician to St. Mary's Hospital, London, and to the Hospital for Epilepsy and Paralysis, Maida Vale, Captain R. A. M. C. (T.), 3rd London General Hospital. Oxford War Primers. London: Henry Frowde (Oxford University Press) and Hodder & Stoughton, 1915. Pp. 127. (Price, $1.25.)

The occasion for this little work arose from the large number of cases of nervous exhaustion and functional paralyses of various kinds encountered in the present European war. The book belongs to the Oxford War Primers, and as such is designed especially to be of assistance to military surgeons under whose care such cases fall, though many contingencies arising in civil practice are likewise referred to. Under suggestive treatment many of the cases of nervous shock clear up rapidly or even immediately. Part I deals with the direct effects of injuries of the nervous system, such as cranial nerve paralyses, concussion, Jacksonian epilepsy, spinal fractures or hemorrhages, and paralyses of the branches of the brachial plexus and of the nerves of the lower extremity. Remote effects are included in the field covered. The author is convinced of the truth of the view that such spinal conditions as progressive muscular atrophy and tabes dorsalis are sometimes excited by injuries or blows upon the back; the necessity of previous syphilitic infection in tabes is, of course, not denied. He has seen harmful effects from splints in wrist drop due to musculospiral paralysis, and much prefers a leather wrist strap with elastic bands leading to the bases of the three inner fingers. In Part II, nervous shock following cerebral injury is discussed. This involves consideration of such conditions as traumatic neurasthenia, general paralysis of the insane, psychasthenia, nervous exhaustion, and hysteria. Suggestions for the detection of a hysterical element in nervous shock cases are given. In the treatment of hysterical anesthesia Harris recommends strong local faradism, to break down the psychic autoinhibition causing the anesthesia, i. e., the stimulus is made so powerful that the patient is forced to admit that he feels. Suggestion soon completes the cure.

The Backward Baby. A Treatise on Idiocy and the Allied Mental Deficiencies in Infancy and Early Childhood. By Herman B. Sheffield, M. D., New York, Fellow of the New York Academy of Medicine and the American Medical Association; Author of Modern Diagnosis and Treatment of Diseases of Children, Pediatric Memoranda, and the Baby's Record and Health, etc. Awarded the Alvarenga Prize of the College of Physicians of Philadelphia, July 14, 1914. With Twenty-two Original Illustrations in the Text. New York: Rebman Company. Pp. vi-184. (Price, $1.00.)

As the author suggests, too little attention has so far been paid to the early stages of idiocy and related conditions in infancy, at a time when there may be still some chance of improving the child's condition before underlying lesions have permanently destroyed cerebral functions. In this small book, awarded the Alvarenga prize of the College of Physicians of Philadelphia, a survey is presented of the etiology, pathology, diagnosis, and treatment of mental deficiencies as they are met with in children less than five years of age. Much of the text is based alone on the author's personal observations, the literature of the subject being as yet scanty. In Chapter I is taken up the general etiology of mental deficiencies, including the influence of heredity, syphilis, alcoholism, consanguinity, uterine disease, ductless gland involvements, traumatism, and febrile diseases. Chapter II deals with the physical examination of the patient and the stigmata and diminished mental standards through which deficient brain functioning can be early recognized. In the third chapter the features of the various special affections, such as microcephalus, hydrocephalus, paralytic amentia, amaurotic family idiocy, mongolism, cretinism, infantilism, and retarded mentality from other causes, are taken up, with numerous photographic illustions. Prophylaxis, discussed in Chapter IV, is considered rich in potentialities, and includes all conditions and regulations tending toward complete fitness for marriage and procreation, together with judicious management of pregnancy and labor, inherent strength of the infant—not procurable after birth—being one of the most essential factors in the prevention of debility. Licensing of midwives is advocated. A definite plan of simple mental training for infants, beginning when they are about three months old, completes the prophylaxis. Active treatment of amentia, described in the last chapter, comprises measures hygienic, pedagogic, physical, dietetic, medicinal, and surgical. Definite directions are given, which will prove a help to the practitioner, sometimes at a loss in these cases. Organotherapy and thyroid transplantation are referred to. A bibliography and index conclude this original and valuable little work.

Lead Poisoning. From the Industrial, Medical, and Social Points of View. Lectures Delivered at The Royal Institute of Public Health by Sir Thomas Oliver, M. A., M. D., M. R. C. P., Consulting Physician, Royal Victoria Infirmary, and Professor of the Principles and Practice of Medicine, University of Durham College of Medicine, Newcastle-upon-Tyne, etc. New York: Paul B. Hoeber, 1914. Pp. x-294. (Price, $2.)

Before taking up the symptomatology and preventive and curative treatment of lead poisoning, the author discusses thoroughly the various occupations in which the poisoning may be acquired, such as lead smelting, the manufacture of red lead and white lead, painting, the manufacture of china, earthenware, and electric accumulators, printing and type founding, plumbing, dyeing, glass making, diamond cutting, etc. The particular susceptibility of women to plumbism is emphasized. At the author's recommendation female labor in the dangerous processes of white lead manufacture has been prohibited in Great Britain, with gratifying results. In the course of his description of the symptoms of lead poisoning, he also notes a marked liability of females exposed to lead to miscarriage and stillbirth, even without previous signs of plumbism. Many cases of obscure illness, characterized chiefly by headache, anemia, gradual mental and physical enfeeblement, insomnia, depression of spirits, and forgetfulness, are to be ascribed to drinking water contaminated with lead, which may be detected upon chemical examination of the urine. In the treatment of lead colic the author recommends sodium monosulphite in half to one grain doses and calcium permanganate in one quarter grain doses. He also praises highly the double electric bath which, since it removes lead from the body, can be used both for therapeutic and diagnostic purposes. The book closes with a large appendix containing the British official factory and workshop regulations in various industries involving the use of lead, such as file cutting, the manufacture of electric accumulators, paints and colors, and pottery, and the smelting of lead containing materials.

A Guide to the Use of Tuberculin. By Archer W. R. Cochrane, M. B. (Lond.), F. R. C. S. (Eng.), Major, Indian Medical Service, Medical Superintendent, King Edward VII Memorial Sanatorium, Bhowali, United Provinces, and Cuthbert A. Sprawson, M. D., B. S. (Lond.), M. R. C. P., Major, Indian Medical Service, Professor of Medicine, King George's Medical College, Lucknow, etc. New York: William Wood & Co., 1915. Pp. vi-181. (Price, $2.25.)

The authors are dissatisfied with previously issued books on tuberculin, on the ground that none of them give sufficiently definite instructions, the practitioner not being relieved of doubt, whether, in a given case, tuberculin should be used at all, and as to what doses should be given. The aim in this work is to formulate rules, hitherto unwritten, which inform the practitioner sufficiently how to proceed in spite of the well recognized and very marked variation in the sensitiveness to tuberculin in different cases. The authors are convinced of the actual therapeutic value of tuberculin. "Clinical experience," they state, "shows that closed cases of the disease never become open if treated with tuberculin." The results to be expected from tuberculin comprise a stimulation of the diseased area to heal (early diagnosis being essential for

this), and a prevention of the spread of the disease. The action of tuberculin is held to consist of a stimulation of antibody production at the focus of disease. Excessive amounts, however, temporarily neutralize and remove all bacteriolysin from the neighborhood of the bacilli, unneutralized tubercle toxin consequently entering the circulation and causing the characteristic tuberculin reaction. In successive chapters are discussed in detail the relative dose of the various tuberculins, the technic of treatment, the tuberculin reaction, the general principles and rules for estimation of the dose in the individual case, the use of tuberculin in diagnosis, the differences between tuberculin treatment in children and adults, the contraindications to tuberculin treatment, and the use of tuberculin in nonpulmonary tuberculous involvements. Eighty-four illustrative temperature curves are interspersed in the text. The value of the work as a whole is increased by the fact that it is based on a definite working hypothesis, justified by the clinical experience of the authors, which permits of the formulation of definite principles and rules to guide those who adopt the treatment.

Muscle Training in the Treatment of Infantile Paralysis. By Wilhelmine G. Wright, Boston Normal School of Gymnastics, 1905; Chirurg.-orthopäd. Klinik of Prof. Dr. A. Hoffa, Berlin, 1908; Assistant to Robert W. Lovett, M. D., Boston. Boston: Ernest Gregory, 1916. Pp. 30. (Price, $0.25.)

In a pamphlet of thirty pages the author presents a comprehensive schedule of exercises designed to develop the latent muscular power of partially paralyzed muscles. The exercises are grouped to cover individual sets of muscles and, taken together, include all the voluntary muscles of the body. She points out the need for careful grading in the employment of these exercises so as not to overtax the weakened muscles, and lays special emphasis on the need for guiding the patient and encouraging his persistence in the development of strength and control. In her opinion the best results are to be secured by having the parents execute the exercises under the guidance of the attending physician, and it is for the instruction of all three that her pamphlet was written. It should meet with a favorable reception by those for whom it is intended, as it carries with it the results of the author's long experience and careful study of this problem.

Interclinical Notes

What we call the "lay papers" are known to French medical editors as the "political journals." The French is a very accurate language.

* * *

A photographic portrait of Dr. Alexis Carrel adorns page 461 of *Leslie's* for October 26th; there is a statement that motion pictures have been taken in France of various operations by this extremely deft surgeon to be used throughout the United States for teaching purposes.

* * *

One of those remarkable handlers of English, an advertisement writer, speaks of Alexander the Great cutting the Gordian knot "in twain." If the celebrated knot was as complicated as history says, a single stroke of the conqueror's sword probably cut it into considerably more pieces than twain.

* * *

A strong little story about an American boy who enlisted in the Canadian forces in order to get a glimpse of the great war, is told in *Leslie's* for October 19th, by Kellogg Speed, M. D., under the title of The Spirit of the Breed. The youthful hero died of gas gangrene after losing an arm by amputation.

* * *

A remarkable paper in the *Survey* for November 4, 1916, is Ourselves and Europe, by Edward T. Devine, in which the writer begs us to take to heart the lessons already learned by the combatants. The work of T. Everit Macy as superintendent of the poor in Westchester county is the subject of a telling essay by Winthrop D. Lane. Another good paper our readers will enjoy is The Mind of a Boy, a psychological study by Helen Thompson Woolley.

E. F. Benson, in his story in the November *Century*, The Sea Green Incorruptible, states that Lord Whittlemere "developed pneumonia." We wish he had allowed the pneumonia to develop, as it is its nature to, and not made of his lordship a sort of conjuror, who might "develop" rabbits from eggs. On page 28 of the same beautiful magazine, St. John G. Ervine, in his Story of the Irish Rebellion, in view of the terrible fate of Sir Roger Casement, which he records, might have used a happier expression concerning his own sentiments than to say "I got tired of *hanging* about O'Connell Street."

* * *

Of special interest to physicians in the November *Current Opinion* are Wherein the Pathological Liar Is Superior to the Truthful Man; The Best Safeguard Against the Dangers of the Sexual Instinct; A Plan to Make All Children Immune to All Acute Infections; A Step Beyond the X Ray in Surgery; An Embryologist's Warning against the Fantastic Tendency of the New Science; and Industrial Miracles Wrought by the Chemist. Perhaps we should add, What Makes a Rubber Tire Blow Out?

* * *

There is a tremendous amount of politics in the *North American Review* for November, some of which no doubt will make curious reading after election day. There is an essay of distinguished quality, however, in Pure Asepsis, by Paul M. Chapman, M. D., a dialogue between a surgeon and a cardinal. There is some verse by the dean of American writers, not very good verse, either, we fear; at all events we like his prose best. There are several essays germane to the United States and her present problems, which are well worth careful reading.

* * *

Current Opinion for November has its usual fascinating budget of good things. It gives an act of *Mr. Lazarus,* but as that drama has exploded or fallen again into the "provinces," the excerpt is merely an aggravation. It summarizes from another magazine the secret of the good health of Admiral Dewey; it seems that this man has attained his seventy-eighth year by never attending banquets, funerals, theatres, or moving pictures, and by being always in bed at least one hour before midnight. Why *Robinson Crusoe* is perennially popular is another interesting chapter in this issue.

* * *

Dialect, in story or drama, is really a very simple matter; the Yorkshireman, the New Englander, the Westerner, the Irishman, always mispronounce the same vowel sounds or diphthongs in the same way. The Irishman's dialect is largely a survival from the time of Queen Anne; he pronounces ea like long a. He says say, tay, playsure, for sea, tea, pleasure; but he does not say thay for the, bare for beer, kane for keen etc. All dialects can be reduced to tabular form and used with perfect accuracy, if writer or speaker will only take the necessary trouble. We are moved to these observations by Dr. Walter M. Brickner's Ignatius Phelan at the Hospital, in the *Survey* for November 4, 1916. Mr. Phelan uses a dialect of his own, that was never heard on sea or land, and is scarcely more Irish than it is Chinese. This is a pity, for Mr. Phelan is distinctly humorous; if his speech was right, the sketch would be a genuine work of art and worthy of its witty author.

* * *

Prior to the establishment of schools for training nurses, every physician had to instruct his own special assistants when he had any. Now the instruction is largely in the hands of graduate nurses, who from their own experience speak more authoritatively than the physician ever could. Consequently nursing and its teaching have taken on an evolution of their own, and the physician may with profit take an occasional look into the courses followed by the intelligent young women who now make a profession of nursing. In no way can he ascertain more quickly and accurately the vast number of interesting and important matters acquired and discussed by the intelligent nurse than by consulting the pages of the *Nurse,* published at Jamestown, N. Y. Conducted with enthusiasm restrained by good taste, beautifully illustrated, ably edited, the *Nurse* is producing a new literature of its own, of a kind that no thoughtful physician can afford to ignore and from which he is sure to gather from time to time some hint of great value.

Meetings of Local Medical Societies

MONDAY, *November 20th.*—New York Academy of Medicine (Section in Ophthalmology); Yorkville Medical Society; Medical Association of the Greater City of New York; Elmira Clinical Society; Psychiatric Society of Ward's Island.

TUESDAY, *November 21st.*—New York Academy of Medicine (Section in Medicine); Tompkins County Medical Society; Tri-Professional Medical Society of New York; Medical Society of the County of Kings; Binghamton Academy of Medicine; Syracuse Academy of Medicine; Ogdensburg Medical Association; Owego Academy of Medicine; Medical Society of the County of Westchester (annual); Federation of Medical Economic Leagues of New York.

WEDNESDAY, *November 22nd.*—New York Academy of Medicine (Section in Laryngology and Rhinology); New York Surgical Society; New York Society of Internal Medicine; Schenectady Academy of Medicine.

THURSDAY, *November 23rd.*—Ex-Interne Society of Seney Hospital, Brooklyn; Medical Union, Buffalo; Hospital Graduates' Club, New York; New York Physicians' Association.

FRIDAY, *November 24th.*—New York Society of German Physicians; New York Clinical Society; Manhattan Medical Society; Society of Alumni of Sloane Hospital for Women; Brooklyn Society of Internal Medicine; Italian Medical Society of New York.

SATURDAY, *November 25th.*—New York Medical and Surgical Society; West End Medical Society; Harvard Medical Society; Lenox Medical and Surgical Society.

Official News

United States Public Health Service:

Official list of changes in the stations and duties of commissioned and other officers of the United States Public Health Service for the seven days ending November 8, 1916:

BAHRENBURG, L. P .H., Surgeon. Detailed to deliver three lectures on public health subjects before the Texas School of Civics and Philanthropy of Houston, Tex., during the period February 6-10, 1917.

BOLTON, JOSEPH, Assistant Surgeon. Granted two days' leave of absence on account of sickness, November 2 and 3, 1916.

BROOKS, S. D., Senior Surgeon. Bureau letter dated October 5, 1916, amended to grant seven days' leave of absence from November 1, 1916.

DERIVAUX, R. C., Assistant Surgeon. Detailed to present a paper on the relation of the Public Health Service to the control of malaria at the meeting of the Southern Medical Association at Atlanta, Ga., November 13-16, 1916.

DESAUSSURE, R. L., Assistant Surgeon. Bureau letter dated October 3, 1916, amended so as to grant eleven days' leave of absence from October 20, 1916.

FREEMAN, A. W., Epidemiologist. Detailed to attend the meeting of the New Jersey Sanitary Association at Lakewood, December 8 and 9, 1916.

FROST, W. H., Passed Assistant Surgeon. Ordered to proceed to Little Rock, Ark., to investigate the prevalence of paralysis among dogs and to secure specimens for laboratory study.

LEAKE, J. P., Passed Assistant Surgeon. Detailed to deliver an address on poliomyelitis at the meeting of the Baltimore City Medical Society, held on November 3, 1916.

LOMBARD, M. S., Assistant Surgeon. Bureau letter dated September 12, 1916, amended so as to grant nine days' leave of absence from October 20, 1916.

OAKLEY, J. H., Surgeon. Detailed to deliver an address on infantile paralysis at the meeting of Ohio Valley Medical Association at Evansville, Ind., November 15-16, 1916.

RUCKER, W. C., Assistant Surgeon General. Granted three days' leave of absence from October 30, 1916.

STILES, CHARLES WARDELL, Professor. Will proceed to New Hanover, Robeson, and Columbus Counties, N. C., to make studies of methods and results of sanitation in those communities.

WHEELER, G. A., Assistant Surgeon. Detailed to attend the meeting of the Southern Medical Association at Atlanta, Ga., November 13-16, 1916.

WILLETS, D. G., Assistant Epidemiologist. Detailed to attend meetings of the Southern Medical Association at Atlanta, Ga., November 13-16, 1916.

WILSON, R. L., Surgeon. Granted two days' leave of absence, November 1-2, 1916, under paragraph 193 Service Regulations.

Boards Convened.

The following officers of the Service have been detailed as members of Coast Guard retiring boards, convened November 8, 1916, as follows: Marine Hospital, Stapleton, N. Y., Senior Surgeon G. W. Stoner and Surgeon A. D. Foster; Custom House, Charleston, S. C., Surgeon W. J. Pettus and Assistant Surgeon P. J. Gorman; Marine Hospital, Baltimore, Md., Surgeon C. W. Vogel and Assistant Surgeon J. D. Stout; Marine Hospital, Boston, Mass., Passed Assistant Surgeon W. M. Bryan and Passed Assistant Surgeon R. A. Kearny.

Board of commissioned medical officers convened at Boston Quarantine Station and other necessary places to investigate fatalities on board steamship *Devonian* in Boston Harbor on November 1, 1916: Detail for the board, Surgeon H. S. Cumming; chairman; Passed Assistant Surgeon W. M. Bryan; Assistant Surgeon F. M. Faget, recorder.

Board of medical officers convened at the Marine Hospital, Cleveland, Ohio, for the reexamination of a detained alien, October 24, 1916: Detail for the board, Surgeon J. M. Holt, chairman; Acting Assistant Surgeon T. S. Keyser, member.

Births, Marriages, and Deaths

Married.

DOLAN-CHAGNON.—In Artic, R. I., on Monday, October 30th, Dr. James E. Dolan, of Randolph, Mass., and Miss Estelle P. Chagnon.

ELLIS-WINTER.—In Colorado Springs, Ky., on Wednesday, October 25th, Dr. Charles Arthur Ellis, of Denver, Col., and Mrs. Minerva Cooley Winter, of Mayfield, Ky.

MACKECHNIE-JANES.—In West Somerville, Mass., on Wednesday, November 1st, Dr. Horace P. Mackechnie and Miss Gertrude M. Janes.

MACKECHNIE-PERRY.—In West Somerville, Mass., on Thursday, November 2nd, Dr. Ernst H. Mackechnie and Miss Aurelia Doris Perry.

Died.

DOLLEY.—In Manila, P. I., on Saturday, October 21st, Dr. Gilman Corson Dolley, aged thirty-seven years.

EICHBERG.—In French Lick Springs, Ind., on Wednesday, November 1, Dr. Julius H. Eichberg, of Avondale, Ohio, aged fifty-nine years.

FREIS.—In Brooklyn, N. Y., on Monday, November 6th, Dr. Eugene A. Freis, aged fifty years.

GOSLING.—In Washington, D. C., on Wednesday, November 1st, Dr. Henry L. Gosling, aged sixty-one years.

IRBY.—In Laurens, S. C., on Thursday, October 26th, Dr. William C. Irby, aged sixty-eight years.

KEISER.—In Columbus, Ohio, on Wednesday, November 1st, Dr. Romeo O. Keiser, aged forty-five years.

LEAKE.—In Dallas, Tex., on Sunday, October 29th, Dr. Henry Kern Leake, aged sixty-nine years.

LEX.—In Irvington, Ky., on Thursday, October 26th, Dr. Edwin A. Lex, of Hardinsburg, aged thirty-nine years.

MCMAHON.—In Courtland, Ala., on Monday, October 30th, Dr. William J. McMahon, aged seventy-eight years.

MASSON.—In Cape Vincent, N. Y., on Thursday, October 26th, Dr. Thomas Masson, aged sixty-five years.

ROBERTS.—In Glencoe, Ohio, on Thursday, October 26th, Dr. Silas F. Roberts.

SCHAUFFLER.—In Kansas City, Mo., on Sunday, October 29th, Dr. Edward W. Schauffler, aged seventy-seven years.

SMITH.—In Hampton, N. H., on Wednesday, November 1st, Dr. Marvin F. Smith, aged sixty-four years.

WEYANT.—In Philadelphia, Pa., on Thursday, November 2nd, Dr. Harry W. Weyant, aged forty-seven years.

THE AFTERTREATMENT OF INFANTILE PARALYSIS.*

BY REGINALD H. SAYRE, M. D.,
New York.

After an attack of anterior poliomyelitis, the result depends largely upon the amount of damage done to the spinal cord while the inflammation was in progress. In the fortunate cases perfect recovery may take place, so that no paralysis is apparent, but in the majority more or less permanent impairment remains, certainly for a long while. We must realize also that children who recover full or nearly full function of the muscles, have nevertheless been through a very severe illness, and for several months should be guarded against too much work, either physical or mental, as careful examination will show hyperexcitability of the nervous system in many, who, at the first glance, appear to be normal.

There is a tendency to recovery in cases in which the damage to the cord has not been permanent, which continues for a long period of time, much longer than used to be imagined, extending over years in fact, and this must not be lost sight of in making a prognosis.

The question of prognosis is a most difficult one. Years ago, I felt that if we had reaction of degeneration, it seemed useless to persevere, as no improvement would be secured in such a muscle. I know now, however, that this is not so, and that some of these apparently paralyzed muscles are capable of much regeneration, and therefore I urge the parents to persist in treatment for years, as I know the results thus to be secured will be infinitely better than if we adopt the pessimistic view that muscles that can improve, will make such improvement as they are capable of whether we help or not, and that the other muscles will not improve no matter what we do, and so there is no use doing anything. Until we can tell which muscles will, and which will not improve, which I do not now believe we are capable of doing, the results will be better if we encourage the patient to try, and not remove the prop of hope by an absolutely black prognosis.

Can we do anythng to improve the condition of these paralyzed patients? Many appear to think that we cannot, and if we assume this attitude, it is very certain that we cannot, but my own experience leads to a very different conclusion, and in cases where the cooperation of the parents can be secured for a sufficient time, improvement is often possible. It must be recognized at the outset that different means must be adopted in different cases, and that persistence in carrying out the treatment is absolutely essential for success. By persistence I do not mean persistence for a week or so, but for several years. The treatment may be divided into medical, electrical, manipulative, instrumental, and surgical. Strychnine, I believe, is distinctly helpful in these cases, and should be exhibited in increasing doses until some result is produced, or the toleration point reached. The intramuscular injection of strychnine which was advocated in former years, was, I believe, so advocated because observers had seen benefit from its employment. This benefit was probably due to the fact that a larger dose of strychnine was given to the patient than in the routine administration of the drug by the stomach, and that it was the increase in quantity rather than the local injection of the drug which was responsible for such improvement.

In regard to the benefits of electrical treatment, the pendulum has swung from the side of enthusiastic advocacy to absolute denial of benefit. Personally I am very sure that I have seen great benefit from the use of faradism and galvanism in these cases. I have had practically no experience with high frequency currents, but some observers report wonderful improvement by their employment. There is no question that cold blue extremities are rendered warm and pink by the use of electricity. I have seen subsequent improvement in the patient which I do not believe would have come without its use. The strength of current which I advocate, is the smallest which will produce muscular contraction. I do not believe that painful applications of electricity are wise. They serve to frighten rather than to benefit the patient.

Manipulations are absolutely essential in the aftertreatment of this disease. They ought never to be employed as long as tenderness of the peripheral nerves exist, but after the limbs have become tolerant of movement. Manipulations of the muscles, deep kneadings, rubbings, and superficial strokings are some of the most essential parts of treatment. It is of the utmost importance to encourage the patient to make voluntary efforts of the paralyzed muscle. If the muscles are too weak to respond to

*Read before the Orthopedic Section, New York Academy of Medicine, October 20, 1916.

the will, the masseur should make the limb go through the required motions while the child endeavors to make the limb do the work which the masseur is doing for it. Just as concentration of the mind on the normal nerve and muscle stimulates the development of that nerve and muscle, just so does this concentration stimulate the growth of the paralyzed muscle. It seems hardly necessary to say that the amount of exercise given a paretic muscle must be very slight lest the muscle be overfatigued, and harm rather than good result, and in the case of little children resort must be had to games to interest their minds and secure their cooperation in the exercise.

In addition to rubbings and handlings, heat applied to these extremities by the electric light oven is of great service, and artificial congestion of the paralyzed extremity by immersion in a vacuum cup is beneficial.

The question of instrumental support comes up in many cases. In the upper extremities it is of comparatively little value, but in the lower extremities it is frequently essential. It should be light and should girdle the limb as little as possible. The muscles are extremely feeble at best, and often are incapable of movement if weighted down with a heavy apparatus. There is also a great tendency on the part of both physician and patient to feel that if they have applied an apparatus, they have done all that is necessary, and to neglect the measures of which I have just spoken, which are essential to the restoration of function, forgetting that the apparatus is merely serving as a crutch for the purpose of assisting locomotion and preventing deformity.

When a growing bone is subject to stress in an abnormal manner, as is the case when one set of muscles is paralyzed and the bones are left under control of the opposing muscles, the direction of growth is very much altered and we frequently see in infantile paralysis knockknees accompanying all sorts of foot deformities. It is essential that these growing bones should be held in as nearly a normal position as possible, and these deformities prevented in order that the skeleton may be straight, and articulate in a normal manner whether we succeed in restoring power to the muscles or not. In adapting any apparatus to the deformed leg it is necessary that the joints of the apparatus be moved in the same axis as the joints of the leg. We frequently find, in untreated cases of infantile paralysis, that the angle is strongly averted, and in order to fit the apparatus to the leg, the ankle joint must be turned out at an angle of forty degrees or so to the knee joint in order to avoid twisting the foot. This fact is often overlooked by both surgeon and instrument maker, and an effort is made to force a crooked leg into a straight splint. The brace should be looked upon always as a temporary affair, and as soon as the patient is able to balance and walk without it, it should be discarded. I feel strongly that braces without joints are a great deterrent, the only possible excuse for their employment being that the patient cannot afford to procure one which has controlled motion.

In cases in which the muscles of the trunk have been affected, there is great danger of curvature of the spine if the patient is allowed to sit up without support before the muscles regain their power. Such patients should be kept recumbent on a hard bed with a very small pillow which should go under the head only and not under the shoulders. The parents and the nurse will be very anxious to prop the patient up with pillows as soon as possible, or to set him up in a chair, but this must be absolutely prohibited, as the soft growing partly cartilaginous vertebræ can be quickly distorted so that all future efforts to straighten the spine will be unavailing.

If the lower extremities and spine are both involved, and the paralysis persists for months, the children are best treated in a wire cuirass in which they can be carried about much like an Indian papoose, and get air and outdoor life while deformity of both limbs and body is prevented. If the paralysis continues in spite of treatment, the question of a corset and leg braces and crutches comes up for consideration.

If the paralysis involves the neck or upper dorsal muscles, a jury mast should be added to support the head and relieve the feeble muscles of undue fatigue. It will be objected to as unsightly, but I tell the parents it is better to see a removable iron over the child's head for a few years than to gaze upon an irremovable hump on its back all its life.

These supports must be removed for the daily exercises, as their constant use tends to cause atrophy of muscles, and the fact that they are a necessary evil to be rid of as soon as possible must not be forgotten.

The number of cases of infantile paralysis which are amenable to surgical treatment is comparatively small, and the majority are better treated by mechanical support, but a certain number derive wonderful help from surgical intervention. Surgery enables some cases to dispense with the use of apparatus altogether, and makes it possible for others to use a much lighter form of support. Surgery may be required either for the muscles, tendons, fascia, bones, or nerves.

In many cases certain groups of affected muscles become shortened, especially the flexor muscles when they are unopposed by the constant stretching action of the extensors. This shortening may at times be overcome by manipulation and mechanical stretching, and at other times will require surgical intervention; but can we decide which means to employ? If when the tissue is stretched to its utmost extent, and point pressure applied to it, a reflex spasm is produced, this tissue has been elongated as far as it is possible to elongate it by stretching, and if it is desired to make it permanently longer this must be done by a surgical operation. This point was insisted upon by the late Lewis A. Sayre, and, I feel sure, is a most valuable guide in determining when to stretch and when to cut. I believe in stretching contracted tissues which are capable of being permanently elongated, but know it is worse than useless to attempt this when tissues cannot be stretched. In the majority of cases where we are called upon to elongate contracted muscles, it is possible to do this by subcutaneous tenotomy. If the tendon is cut subcutaneously the deformity should be corrected im-

mediately, and if a proper dressing is applied, there need be no fear of nonunion of the tendons. I have seen as much as three inches of the Achilles tendon reproduced after subcutaneous tenotomy. In operating upon the tendo Achillis for example, after the separation of the ends of the divided tendons, a distinct gap is felt between them. This should be covered by a stout piece of adhesive plaster or some dressing firm enough to keep the bandages from occluding the gap between the tendon ends. The space between the tendon ends will be filled with lymph into which new tendon cells will grow until the gap is filled up by new tendon which in a few months time cannot be distinguished under the microscope from the original. If, however, the gap is closed by a tight bandage, it is possible to get nonunion of the tendon, and failure to observe that the gap is thus occluded has caused nonunion in some cases, and led observers to condemn this method of treatment and advocate other modes of tendon elongation. In the great majority of cases these methods are unnecessarily tedious and much more complicated than subcutaneous tenotomy and productive of no better results. In some instances, however, as in contractures of the long flexors of the fingers, open operation of the forearm tendons is advisable. A number of different operations have been suggested, the best being the splitting of the tendon longitudinally, cutting the slit loose on each side and sliding the flaps on each other. The Z shaped incision with the opening out of the legs of the Z has also been practised. In operating upon the hamstrings open incision is usually advisable, as operators have been known to mistake the external popliteal nerve for the biceps tendon and to divide it. When operating by the open method at the knee, it has been my custom simply to divide the tendons and close the wound with sutures, making no attempts at sliding elongation. I have never seen failure of the tendon to reform after this operation. The psoas and iliacus should be divided by open operation, as their proximity to the femoral artery makes subcutaneous division dangerous.

The question of transplantation of the force of an unparalyzed muscle to a paralyzed one, was first suggested by Nicoladoni, and independently in this country, by Dr. B. F. Parrish, formerly of this city. At the time, 1892, that I showed a patient before the Orthopedic Section of the Academy of Medicine, on whom I had operated at Doctor Parrish's suggestion, by transferring the live tendon of the extensor hallucis to the paralyzed anterior tibial, we both supposed the operation original with Doctor Parrish, and it was not until some months afterwards that Doctor Whitman drew the attention of the section to the fact that Nicoladoni had suggesed it ten years previously. Nicoladoni operated by transplanting the peronei into the tendo Achillis, while Parrish suggested sewing the extensor proprius hallucis to the tibialis anticus.

Tendon transference has been of great benefit in cases of paralysis and will often enable a patient to dispense with apparatus. In order to be practicable a strong muscle is necessary whose force can be diverted and made to do the work of its paralyzed neighbor. Unfortunately this condition very frequently does not exist, and all the muscles in the limb are so feeble that it is useless to endeavor to borrow strength from any. Occasionally it is possible by electricity and massage, and gymnastics to develop the feeble muscle into a vigorous one, and subsequently operate. Certain details of technic must be observed in order to get the best results in tendon transplantation. If sepsis takes place or if we have pressure necrosis from sutures which are too tight, the result will be a failure. Unless the foot is put in plaster of Paris in a position to relieve the newly attached tendon from strain, the result is apt to be a failure. All the slack must be taken up at the time the tendon is sutured in position, else when the muscle contracts insufficient force will be exerted at the point of attachment. In some cases we may divide the tendon of the strong muscle completely, and attach it either to the tendon of the paralyzed muscle, or in suitable instances to the periosteum of the bone upon which we wish to make traction. It may be wise to drill a hole in the bone and pass the tendon through it to make sure of a firm union. Some writers prefer to split the tendon of the strong muscle, using part of it in the way just described, and leaving the rest to perform its own function. In case the tendon is too short to reach the desired point of implantation, it can be lengthened by means of a silk cord. In order to be of great use the muscle which is transplanted must be powerful enough to take the place of the one which is paralyzed, and one reason that operations for muscle transference in cases of talipes calcaneus have been so unsatisfactory is because the peronei and the tibials are absolutely inadequate to do the work of the gastrocnemius and soleus. The flexors and the extensors of the forearm have been interchanged, and the sartorius and the hamstring muscles, sometimes one and sometimes all, have been transplanted to the patella to overcome paralysis of the quadriceps extensor femoris, with great success. Care should be taken to leave enough muscle behind the knee to balance the extensor power of the transplanted muscles or hyperextension of the knee may result, with most disastrous consequences to the patient. Galle has changed the tendons of paralyzed muscles into ligaments for the purpose of holding the ankle joint firm, by cutting canals in the tibia and fibula subperiosteally and then, after imbedding the tendons in these canals, sewing the periosteum over them. In suitable cases this operation gives good results.

The question of nerve transference has been investigated extensively in the last few years, especially since the papers of Spitzy and Young, before the American Orthopedic Association, in 1904. The results of nerve transplantation and nerve splicing after traumatic paralysis, have given such remarkable satisfaction that investigators have hoped for brilliant results in cases of infantile paralysis. The theory upon which operations have been based, is, that if a healthy nerve coming from a healthy part of the spinal cord, is attached to the distal extremity of a paralyzed nerve, the latter will still be capable of regeneration and become able to transmit impulse and sensation. Many elaborate demonstrations of the technic of the operations have been made, some of the observers insisting upon the necessity of an

end to end anastomosis, and others believing that it is sufficient to cut a slit in the nerve and insert in this the end of the divided nerve, retaining it in position by two or three stitches. I have seen only a few cases where I thought operation was indicated, and the results in all I have done so far have been failures. A number of observers have reported brilliant successes, but the results in the cases which I have personally seen, have not appeared as good to me as they did to the gentlemen who had operated upon them, and the failure of exact statement as to the amount of paralysis present before operation, has made comparison of the conditions before and after operation extremely difficult. I feel personally that the operation should be tried in suitable cases, but do not feel that it has yet been shown that a nerve which has been paralyzed for a long time can be regenerated by splicing it to a live one. The question of nerve suture and nerve transplantation in paralysis is of vast importance. It is necessary in discussing its possibilities to recognize that the different kinds of paralysis as we see them in young children have different origins, and unless this is borne in mind operations will be undertaken which have little promise of success.

The results of immediate suture of nerves which have been divided either accidentally or on purpose, and the bridging of the defects where the nerves could not be approximated, have given such brilliant results that it was to be expected that in cases of traumatic paralysis, like the brachial palsy of Erb, benefit might follow the removal of scar tissue and suturing nerve trunks. In anterior poliomyelitis, however, the condition is different, and the results which are obtained by the experimental transplantation of healthy nerves in animals and of nerve suture after injury in man should not be relied upon as giving hope that an equally favorable result will follow a similar operation on a diseased nerve.

We now come to the bone operations that may become necessary in paralysis.

When a growing bone is compelled to bear weight while imperfectly supported, as is the case in infantile paralysis affecting the lower extremity, it frequently becomes deformed, and bone operations are sometimes necessary in addition to operations on the soft parts. When the extensor muscles of the thigh and leg are paralyzed, it is often the case that after a clubfoot has been restored to its normal relation with the leg, it will be found to be everted forty-five or fifty-five degrees on account of a twist which has taken place at the knee, so that the knee and ankle joints work no longer in the same plane, but at a marked angle to each other, and in such cases an osteotomy of both bones of the leg is sometimes necessary to bring the knee and ankle joints into line. At other times a pronounced genu valgum results from the paralysis of the quadriceps femoris and an osteotomy or osteoclasis of the femur is necessary to put the foot under the body and restore the centre of gravity. At other times the lower articular surface of the tibia is not parallel with the ground and an osteotomy must be done just above the ankle joint to remedy this condition and prevent eversion or inversion of the foot. By thus restoring the balance of the body, many patients dispense with apparatus.

In connection with dangle foot, or with talipes calcaneus bone operations have been of marked use. Arthrodesis, or the formation of an artificial ankylosis is of great use in many of these cases. It is by no means so easy to produce a stable artificial ankylosis as would be imagined, and a large variety of operations have in consequence been devised to keep the foot firmly against the leg at a right angle.

The majority make an incision behind the outer malleolus running forward below it and into the instep, dividing the external lateral ligaments and dislocating the astragalus so as to gain access to its top and sides, which are then denuded of cartilage. In the great majority of cases it is also necessary to obliterate the joint between the astragalus and os calcis, and many operators prefer therefore to remove the astragalus altogether.

In order to facilitate the operation, Goldthwaite divides the fibula a few inches above the joint and does this also in order that the divided fibula may be more certainly brought into contact with the astragalus.

The front part of the foot is apt to be unstable in these cases unless the mediotarsal articulation is also obliterated at the same time that the arthrodesis is effected at the ankle joint.

In talipes calcaneus the operation devised by Whitman has given most excellent results. The astragalus is removed, a thin section of bone is then cut from the outer surface of the os calcis and cuboid. On the inner side the sustentaculum tali is cut away and the calcaneonavicular ligament is partially separated from its attachments. The cartilage is then removed from the two malleoli and if necessary they are reshaped to permit accurate adjustment. The foot is then displaced backward as far as possible so that the external malleolus may cover the calcaneocuboid junction, while the inner malleolus is forced into the depression behind the navicular. The peronei tendons which were divided at the first stage of the operation are then attached to the insertion of the tendo Achillis and to the os calcis by strong silk sutures. The object of the removal of the astragalus is to assure stability and to prevent lateral deformity by placing the leg bones directly on the foot. The object of the backward displacement of the foot is to direct the weight upon its centre and thus remove the adverse leverage which induces dorsal flexion.

In cases of flail knee, arthrodesis has been advised and in selected cases, is undoubtedly a useful operation. It has various objections, however, which do not hold good in the case of the ankle. A patient with a stiff knee is much hampered in sitting down, and in the majority of occupations is more comfortable when supplied with an apparatus which allows flexion while sitting down than if the leg is held rigidly in extension all the time. The operation is advocated by some on the grounds that it is too expensive for a poor man to use a splint, but it seems to me that this position is illogical. If a man's joint is resected, he is incapacitated from work for a period of three months. Supposing he earns ten dollars a week, this is a loss of one hundred and twenty dollars. The cost of his support in any hospital during this period would be two dollars a day, in a great many hospitals a

larger sum. This will make one hundred and eighty dollars. The cost of the surgeon's time during the operation should be taken into account, as it is fair to presume that even if we make no charge for the operation—it being done in the hospital—nevertheless the time consumed might be put to a profitable account elsewhere by the surgeon, so let us charge twenty dollars for the surgeon's time, making three hundred and twenty dollars in all. This sum invested at 4.5 per cent. would bring in fourteen dollars and forty cents per annum, more than enough to purchase the original splint and keep it in repair during the patient's life. I believe that many operations which are advocated on the grounds of economy are really more costly than conservative measures if we examine the situation with care. Provided that an operation is to be done on the knee, obviously it should be deferred until after the cessation of bone growth, as early resections of the knee are apt to result in great permanent shortening from the interference with the epiphyseal cartilage. In the hip, when the gluteal muscles are completely paralyzed, it may be wise to perform an arthrodesis, cutting off the upper edge of the femoral head and gouging out the acetabulum, thus allowing two raw bony surfaces to come in contact and so form a secure union, as suggested by Albee in painful arthritic conditions. Here again the question of the usefulness of an ankyloid hip must be considered.

These cases of gluteal paralysis give the most difficult problems with which we have to deal, and present the most unfavorable prognosis.

Many patients walk quite well who have almost no power in the quadriceps femoris, but have a well balanced knee joint, but the patient with paralyzed glutei is in most unstable equilibrium and can rarely do without apparatus if the paralysis is bilateral.

To summarize the treatment, I would say: Do not do too much at first, give the patient absolute rest for many weeks. Prevent deformities by opposing contracting muscles. Later on, use gentle massage movements, active, passive, and restrictive. Endeavor to reestablish the path of nerve control to the muscle. Aid this by electric stimulation in suitable cases. If necessary, employ support to prevent undue stretching of muscles, or ligaments, or deformity of bones. Later on, if deformities have developed, do such surgical operation as may be necessary to put the skeleton in a position best to support weight, and to balance the opposing force of muscles so as to preserve equilibrium. By these means many patients who otherwise would be hopelessly bedridden, will be enabled to go about in comparative comfort.

14 West Forty-eighth Street.

Operative Procedures Employed in the Treatment of the Residual Paralysis of Poliomyelitis.—Berard Bartow and William Ward Plummer (*American Journal of Orthopedic Surgery*, October, 1916) make a brief report of 154 operative cases of poliomyelitis in which many surgical methods were used. The majority of the cases showed improvement.

EPILEPTOGENOUS ZONES IN ORGANIC EPILEPSY.

By Alfred Gordon, M. D.,
Philadelphia,
Neurologist, Mount Sinai, Northwestern, General, and Douglass Memorial Hospitals.

Review of the literature on organic epilepsy reveals a wide diversity of opinion concerning the pathological findings. While each of these views has its *raison d'être*, yet none is totally satisfactory for a general conception concerning all varieties of epilepsy. Apart from Marshall Hall's theory of the medullary origin of epilepsy, in which there is supposed to be a sudden stimulation of bulbar centres followed by a stasis of cerebral circulation, or, as Brown-Sequard explains it, there is anemia of the cerebrum leading to unconsciousness; apart also from Fritch and Hitzig's experimental investigations demonstrating convulsive seizures by the stimulation of certain cortical areas; apart from Meynert's sclerosis of the cornu ammonis as being an epileptogenous centre; apart from Chaslin's and Bleuler's gliosis of the cortex; apart from all these important anatomical findings, which are only a few among many alleged to be the direct causes of epilepsy—Hughling Jackson's views appear to conform most with the underlying physiological condition of the disease.

He considers organic epilepsy as a three level affection. According to him the central nervous system is composed of three superimposed levels representing degrees of evolution more and more advanced. In the lowest level cases epilepsy is caused by an involvement of the upper spinal system, medulla, pons, and the cerebellum. There the pontobulbar convulsions originate. Laryngismus stridulus belongs to this group of cases. In the middle level type the cortical motor and sensory areas, also the corpora striata, are the direct cause of epilepsy. Here loss of consciousness may or may not be present; the latter is not essential. In the superior level epilepsy the lesion lies in the prefrontal lobe. Here unconsciousness is an inevitable phenomenon and its presence is an indication that an epileptic discharge begins in the highest centres. This level presides over epilepsy proper.

Jackson's conception of epilepsy, therefore, shows a great variety of localizations as the origin of convulsions. On the other hand, if we recall the case cited by Gowers (*Epilepsy and Other Chronic Disorders*, London, 1881), in which an epileptic suddenly had an attack of apoplexy with hemiplegia, and the convulsions disappeared on the paralyzed side; also if we consider the case of Prus (Ueber die Leitungsbahnen und Pathogenese der Rinden-Epilepsie, *Wiener klinische Wochenschrift*, 38, 1898), in which painting of the motor cortex with cocaine prevented generalized convulsions; if we consider these cases, we are led to admit that the cells of the motor cortex play a predominant role in epileptic seizures, and that of the three levels in the classification the middle level zone is the most acceptable, as it corresponds more accurately with the clinical facts.

While H. Jackson's views apparently embrace a very large pathological field of epilepsy, neverthe-

less they do not cover all anatomical occurrences, such as the above mentioned lesion of the cornu ammonis, the superficial cortical gliosis of some writers (especially Southard), degeneration of cells in the second cortical layer (Bevan Lewis, Clark, and Prout), lesions of the uncus, of hippocampal and temporal gyri (Southard), and lesions of the meninges and calvarium.

Beside these manifold epileptogenic zones found in cases of organic epilepsy, there is one which, although not frequent, is nevertheless of sufficient importance to be considered here. I mean the ventricular walls of the brain. (See also E. C. Fischbein's excellent monograph in the *Proceedings* of the Association for the Study of Epilepsy, etc., 1914.) D. Ferrier in Part VI of his book, *Functions of the Brain*, 1886, says: "I have found that electrical stimulation applied to the surface of the ventricular nucleus of the corpus striatum in the monkey, cat, dog, jackal, and rabbit causes precisely the same results, viz., a condition of pleurosthotonus, or general muscular contraction on the opposite side of the body. The head is drawn strongly to

Fig.—Ependyma of anterior cornu of lateral ventricles. It is thickened and covered with nodules of various sizes and form. Cellular infiltration in nodules and in enlarged bloodvessels.

the side, and the body bent in the form of an arch with the concavity to the opposite side; the facial muscles are thrown into spasmodic contractions and the limbs are rigid in the position of equilibrium between the flexors and extensors, the flexors predominating. . . . There is no differentiation of movement from any point of the ventricular aspect of the ganglion, all the actions differentiated in the cortical centres being simultaneously called into play." Ferrier's results had been corroborated by the experiments of Corville and Duret. Ventricular surfaces are covered by ependymal lining membranes consisting of columnar and ciliated epithelium. In the ventricular cavity in a state of suspension lie the choroid plexuses with their villi, which are constantly brought into contact with the ependyma of the ventricular walls. Should the latter be in a state of inflammation or otherwise abnormally disturbed, there will be sufficient cause for the villous processes of the choroid plexuses to produce an irritation in the brain, and, through the process of diffusion of stimulus to the cortex along association fibres, to lead to reactions such as epileptic convulsions.

An epididymitis has the same reacting value as the above mentioned general gliosis or sclerosis of the cornu ammonis, or other lesions in the brain which have been found in cases of organic epilepsy. In fact, a lesion of any portion of the brain may be accompanied by epileptic seizures and therefore may be considered as an epileptogenous zone. The multiplicity of lesions observed in cases of organic epilepsy warrant such a conclusion. It seems therefore logical to infer that stimulating surfaces may be localized in any portion of the central nervous system, and the reception of the stimuli and the discharge of motor power are the province of the motor cells of the cortex. Not one of the lesional foci described can lay claim to pathognomonicity.

The present case is one of those infrequent occurrences which gave place to a focal epilepsy, as if the primary pathological condition had been situated directly in the Rolandic area of the cortex. It adds a new document to those already existing which concern a vast variety of foci found in organic epilepsy. It has no pretension to solve the intimate physiological mechanism of an epileptic attack, which remains as obscure as ever, but it warrants being placed on record on account of its unusual localization, of the very peculiar character of the lesion, and of being corroborative of the foregoing contention, namely, that a multiplicity of lesions in the cerebrum may be considered as epileptogenous zones.

Ventricular primary foci in organic epilepsy have been very rarely reported. The lesion in the present case was confined to the anterior cornua of the lateral ventricles exclusively, more in the right than in the left. The entire surface of the right cornu was covered with miliary nodules thickly crowded. In the left corner there were but a few nodules. As this was the only material lesion in the brain (as proved histologically), it is evident that it behaved like an active epileptogenous focus. It acted as a receptive surface, which transmitted its powerful stimulation to the cells of the motor area and produced convulsive discharges.

An analysis of this case, as well as of cases with lesions elsewhere in the brain, leads to the conclusion that the mechanism of epileptic convulsions lies fundamentally in the disturbed function of the cortical motor cells the impulses of which are influenced by morbid foci in any region of the cerebrum. The above mentioned cases, in one of which painting of the motor cortex with cocaine and in the other supervening hemiplegia—suspended convulsions on one side—throw the entire burden of epileptic impulses upon the cortical elements. Therein lies the main station to which flow the abnormal nervous currents originating from any irritated source in the brain, and in which abnormal activity is initiated with the result of abnormal muscular movements. The following case presents interesting features from the standpoint of epileptogenous areas in organic epilepsy:

Case. Ch. T., colored, aged forty-two years, was admitted to the Douglass Hospital November 7, 1914, in a state of hebetude. His left arm was subject to constant twitchings even when the limb was at rest. These movements became accentuated upon voluntary acts and were markedly evident in finger to nose movements. The grip of the left hand was much weaker than that of the right. The biceps and triceps reflexes were not obtainable on both sides. The knee jerks were difficult to obtain on both sides. No ankle clonus on either side. Stroking the sole

of the left foot gave no response, but on the right side there was a distinct Babinski.

There was a distinct deviation of the lower face toward the right. Astereognosis was present in the left hand, but not in the right. The sense of position was abolished in the left hand, so that when he was asked to find it he was unable to do it, and when asked to carry a glass to the mouth he could not do it correctly with the left hand. The pain sense was diminished, but touch and temperature senses were preserved in the left arm.

During the two weeks spent in the hospital the patient had six convulsive attacks with loss of consciousness. In each the convulsive movements were confined exclusively to the left arm and the head was turned to the left side. In the interval the arm showed a tremor, especially upon voluntary movements during the first eight days, but tremor disappeared during the latter eight days. Doctor Appelman noted that the ocular movements seemed limited, being unable to rotate far to the left of the median line; upward, downward, and right rotation being normal. Pupils were equal and reacted to direct light. Visual fields to the left in each eye seemed impaired. Media were clear in both eyes, discs were oval, outline and color were good, and there was no lesion of the retina or bloodvessels. Vision of both eyes was 10/200.

The patient's condition pointed to a right sided lesion in the brain. In favor of it, spoke the convulsive movements with and without loss of consciousness confined to the left arm; the turning of the head to the left during the convulsive seizures; the ataxia and astereognosis of left upper extremity, and the left sided hemianopsia. An exploratory or decompressive operation was declined by the patient's relatives. Three days before he died there was a sudden rise of nocturnal temperature to 103.3° F. with a diurnal fall to 97° F.; the convulsions became very frequent and in one of the seizures the patient died.

AUTOPSY.

At autopsy all the abdominal and thoracic viscera were found apparently normal. The brain, after being hardened, presented on transverse anteroposterior section most unusual findings confined exclusively to the anterior cornua of the lateral ventricles. The lesion was pronounced in the right horn and only slightly evident in the left horn. There was an unusually large quantity of fluid in both cornua.

The ependyma had lost its uniform smoothness and was covered by numberless miliary nodules. Histologically the latter presented cells of partly necrotic material, some of them under the ependyma, some had destroyed it, and some were on its surface. Their relative size was not equal, some of them being larger and longer than others; some were very close to the surface, others were loosely attached to the surface, and formed thick branches at a certain distance from the surface. They consisted of crowded round cells which followed the branches of the original nodules. In the vicinity many vessels had mononuclear cells similar to those of the nodules. Some bloodvessels were thrombotic and very much dilated, and had thickened walls. In the latter the inner layer was shriveled and torn in some places. The ependyma itself immediately beneath the miliary nodules was much thickened, and covered thickly between the nodules by round cells. In some areas there was solution of continuity of the ependyma, which solution continued deep in the subependymal tissue. The inner walls of the separated portions were covered with round cells.

As to the nature of the ependymal nodules, it is difficult to say. They do not have the histology of tubercles. It would seem reasonable to call them miliary gummata, in which opinion Dr. A. G. Ellis fully concurs. This view is substantiated, I think, by the fact that many vessels in the vicinity have mononuclear cells in their walls.

Value of Quinoidine in Malaria.—E. E. Waters (*Indian Medical Gazette*, September, 1916) says that when properly administered quinoidine is at least as effective as quinine and causes no cinchonism or gastric trouble.

INJURIES TO THE SPINAL CORD PRODUCED BY MODERN WARFARE.*

By C. BURNS CRAIG, M. D.,
New York,
Assistant Physician, Neurological Institute.

Wounds of the nervous system occurring in war are similar to those incident to civil life. The difference is quantitative not qualitative. Organic injuries to the nervous system may be grouped under: 1. Concussion; 2, contusion or laceration; and, 3, compression. The peripheral nerve trunks[1], because of their structure and the nature of the tissues surrounding them, are not susceptible to concussion. Therefore injuries to the nerves and plexuses are in the main, contusions and lacerations. Compression from scar tissue formation produces a comparatively small number of nerve injuries.

Nerve contusion, in which continuity is not severed, recovers slowly, but complete restoration of function may occur. Contusion of greater severity, which severs continuity, produces a lesion, the outcome of which is unfavorable. The character of these wounds is doubtless responsible for the unfortunate results. They are all infected and a month or more elapses before the purulent discharge ceases and a clean surface is offered for operation. By that time the severed nerve ends have not only retracted, but have become imbedded in scar tissues of great density. The peripheral segment may, also, have degenerated.

The difficulty of approximating the severed ends is often further increased by loss of substance. This necessitates nerve extension and the use of bridging devices to hold the cut ends in contact. During ten months with the American ambulance in France I observed no improvement in cases of nerve suture. On the other hand, compression of nerve trunks due to bone callus and scar formation causes paralysis which gradually disappears if the offending tissue is removed early.

Wounds of the central nervous system are either benign and result in comparatively early recovery, or they are fatal. The prognosis in lacerations of the brain and spinal cord is almost hopeless. Such cases show little improvement after the initial shock disappears. Upward of ninety per cent. of lacerated wounds of the brain are infected, and the victims acquire meningitis and die. The few who recover usually exhibit residual paralysis. When the injury to the brain is one of compression due to depressed fracture, early removal of the displaced bone yields favorable results, provided that the infection in the wound does not invade the meninges. When the injury to the brain is simple concussion, recovery is remarkably rapid and is usually complete in from two to four weeks.

Laceration of the spinal cord causes paraplegia, quadriplegia, or cauda equina symptoms. The patients manifest cystitis, pyelonephritis, and general sepsis with a fatal termination within nine months.

*Read at the meeting of the American Neurological Association, Washington, D. C., May 9, 1916.

[1]Injuries to Peripheral Nerves Occurring in War was discussed October, 1915, before the joint meeting of the Neurological Section of the New York Academy of Medicine and the New York Neurological Society. To appear in the *Am. Jour. Medical Sciences*.

If we except the amaurotic, the paraplegic are the most dejected group of wounded. Their presence has a very depressing effect upon the less seriously wounded. They are a great problem in a military hospital where beds are in demand for those who can be benefited. The expedient of putting them all in one ward was tried at the American ambulance. This facilitated nursing, but served to in-

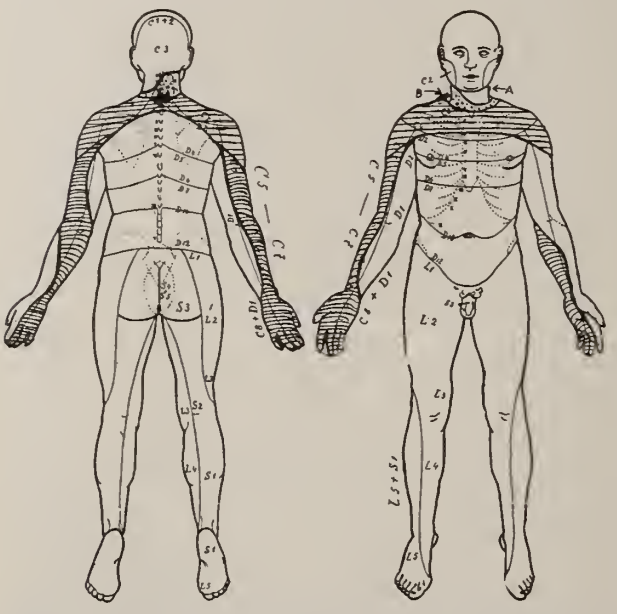

Fig. 1.—Collar of hyperesthesia, band of hypesthesia across the chest and shoulder, and anesthesia of the arms. Spinal canal not penetrated. A, wound of entrance; B, exit.

crease their depression. Incurable from the outset, they dragged out the most miserable existence possible for human beings. In the meantime, their agony was beyond description. Those wounded low down in the spinal cord invariably suffered pains in the lower extremities and bladder which seldom left them, lancinating in type and comparable to the most severe pains of tabes. Incontinence of bladder and bowels always existed and despite the greatest care, multiple bedsores developed. As catheterization was always necessary in these cases, cystitis invariably developed, and when the infection extended to the kidneys, it marked the beginning of the end.

Concussion of the spinal cord presents a brighter picture. Concussion with hematomyelia, causing paraplegia or quadriplegia, may follow the impinging of a bullet or shell fragment upon the vertebra without producing fracture of the latter. Such cases present all grades of sensory and flaccid motor paralysis and usually end in entire recovery. The degree and the rapidity of recovery are in some instances amazing.

This article is based upon a study of thirty patients. From these I have selected thirteen typical cases which, I believe, illustrate the types of spinal cord lesions resulting from gunshot wounds.

Case I. Concussion of the spinal cord and hematomyelia; lesion extending from the third cervical to the first dorsal segment; complete paralysis below the neck, recovery in two months. A well developed muscular man of twenty-one years was struck in the left shoulder by a rifle ball June 6, 1915. He fell and lost consciousness immediately. He recovered consciousness ten hours later. He was admitted to Doctor Blake's service in the American ambulance two days later. Examination showed the wound of entrance to be a circular perforation, one cm. in diameter, in the left sternocleidomastoid, seven cm. below the tip of the mastoid. The slitlike wound of exit, was in the right trapezius just above the scapula. A line connecting the two passed between the fourth and fifth cervical vertebræ. The cervical spine was exquisitely sensitive and the neck was held rigidly. There was a complete flaccid motor quadriplegia. A collar of hyperesthesia about two cm. wide encircled the base of the neck. Below this was an area of hypesthesia extending across the chest and back down to the second rib anteriorly, and to the first dorsal vertebra posteriorly, and out across both shoulders; there was anesthesia over the radial half of the right arm and including the hand. An anesthetic band wound, spirally from the shoulder down the back of the left arm crossed at the elbow, and involved the ulnar half of the arm, front and back. The remainder of the arm apparently retained normal sensation. The superficial and tendon reflexes were abolished. X ray examination showed an intact spinal column and no foreign body. He complained of tingling and numbness in the hands and arms, more pronounced in the latter. It was evident from the sensory examination that damage had been done the spinal cord, involving the segments from the third to the eighth cervical. On the left side the lesion included the first dorsal. It involved, of course, the descending motor tracts of the legs as well as the arms.

Twenty-four hours later, the patient began feebly to move the feet and arms; after another interval of three days he began to flex the fingers of the right hand, and movements of the legs showed increased strength. He could not pronate and supinate the right forearm. By June 15th, the area of hypesthesia had cleared up remarkably, although still distinguishable. The tendon jerks of the arms were absent, those of the lower extremities lively. There was no clonus or Babinski phenomenon. The superficial reflexes were absent. The infected wound was draining satisfactorily, the patient's temperature averaging 102° F.

The patient improved day by day so that by June 28th the wound of entrance was entirely healed and the exit

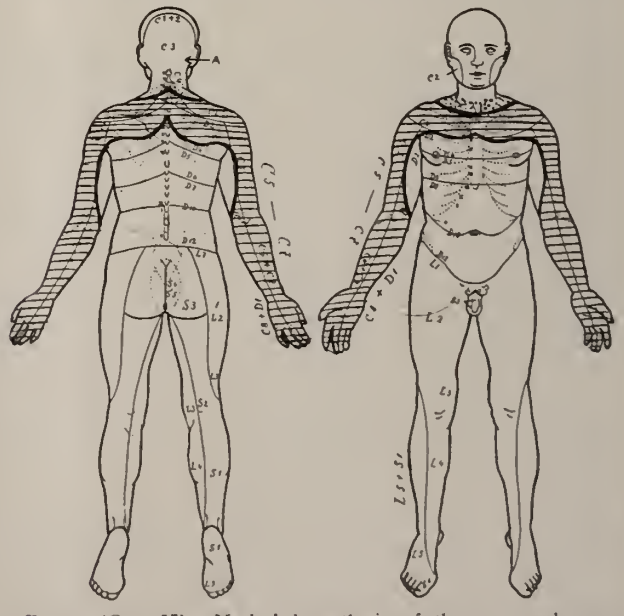

Fig. 2 (Case II).—Marked hypesthesia of the arms and upper thorax, with collar of hyperesthesia above. Spinal canal not penetrated. A, wound.

wound was healthy and granulating. He no longer had fever. The movements of the right arm and hand had become fairly complete, though feeble, and he could feed himself. The movements of the left arm had also returned, but the only movement possible with the left hand was feeble approximation of the thumb and index finger. The tendon reflexes in both arms had returned. The lower extremities showed complete return of motion, and nearly

complete recovery of strength, but the reflexes were very lively. The fourth and fifth cervical spines were still tender. Within a month he regained use of the left upper extremity, was discharged, and returned to service.

Case II. Concussion and hematomyelia involving the cervical cord from the third to the eighth segment inclusive, complicated by transient aphasia; wound just below the occipital bone; paralysis of both arms; recovery practically complete in eight weeks. This patient, a man twenty-three years old, wounded April 27, 1915, was admitted to the hospital in Dr. Du Bouchet's service, two days later. He was struck by a shell which exploded seven to ten metres behind him and two or three metres in the air. He was blown from a sitting posture five or six metres forward and fell upon his face. He was unable to move, save the head and neck. He experienced no pain, but was unable to speak for ten minutes. He then began to stammer, and after half an hour could speak without difficulty. He was also able to move his legs feebly. After lying four hours he was able to get up and walk, tremblingly and with very short steps. When upright both arms hung limply at his sides.

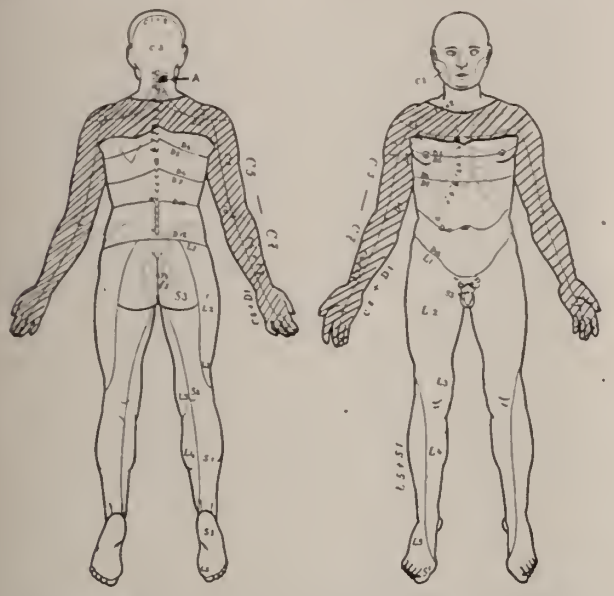

Fig. 3 (Case III).—Area of pronounced hypesthesia due to hematomyelia without penetration of the spinal canal by the missile. A, wound of exit.

Examination at the time of admission showed a small penetrating wound just to the right of the first spinous process and just below the border of the occipital bone. There was an area of hypesthesia extending from the clavicle to the second intercostal space in front, and from the sixth cervical to the second dorsal spinous process posteriorly. This area continued over both shoulders and involved the outer surface of both forearms and hands. Above this was a narrow collar of hyperesthesia around the base of the neck. The arms lay at the sides, but the patient could raise them feebly, and flexion and extension of the fingers and hands and arms could be performed feebly. Such effort was not accompanied by pain. The muscles of the arms and hands were tender to pressure. The lower extremities could be moved freely. The sphincters of the bladder and bowels functioned, although he did not urinate for twelve hours after he was injured. The tendon reflexes in the arms and legs were present. Those of the right leg were slightly livelier than those of the left. Motor power in the legs was good. The superficial reflexes were normal.

An x ray examination showed some extremely small fragments of shell about the size of grains of wheat close to the vertebra upon the right lamina. On May 3d these were removed by Doctor Chauveau with an electric magnet, as were also two small fragments of spinous process. It seemed probable that the offending missile had struck the spine and ricocheted out of the wound, leaving only small fragments behind.

The patient improved rapidly, although he continued to complain of numbness in the hands and feet, and by May 15th considerable strength had returned in the left arm and hand. Tested for astereognosis, large objects were named correctly, but not small ones. By May 31st, the tenderness had disappeared from the arms, and there was no pain on movement. Disability in naming objects held in the hand was less, and the reflexes which were at first sluggish, were now lively. A fair degree of strength had returned to the left hand, but the right was still feeble, the extensors being weaker than the flexors. Sometimes when lying quietly a sensation like an "electric shock" would pass from his feet to his head, and the entire body "jumped." There was also a sensation as though the arms and legs were incased in rubber tights. The area of hypesthesia persisted, but was less pronounced.

Improvement continued rapidly, the wound healing without check. By June 22d, practically all movements could be performed by the hands and arms. The grip of the right hand, which was the last to recover, was still weak, and he could not retain a pen in writing. The narrow band of hyperesthesia still persisted around the neck, although the area of hypesthesia could not be mapped out with certainty. He was discharged as convalescent and returned to service in three weeks.

Case III. Concussion of the spinal cord and hematomyelia extending from the third to the eighth cervical segment. Paralysis of the arms associated with transient aphasia. Recovery in five weeks. Patient was a well developed man of twenty-two years, wounded by a bursting shell May 25, 1915. A fragment struck him in the neck. He fell and was unconscious for an hour. On regaining consciousness he was unable to speak for half an hour. He was able to move only his head, and his body was tingling all over. After several futile attempts he got upon his feet and walked sixty metres to the trench, where he rested for seven hours. He was unable to stand again and was carried to the rear and admitted to Dr. Joseph Blake's service in the American ambulance the following day. There was a small wound of entrance in the right side of the neck just below the angle of the jaw, with wound of exit three cm. in diameter on the same side of the fifth cervical spine, accompanied by marked induration of the right side of the neck. His hearing, sight, and

Fig. 4 (Case IV).—Concussion and hematomyelia.

ability to speak and swallow were not impaired. Although he complained of numbness and tingling in his feet, he could move the lower extremities quite well and had good strength in them. The arms and hands lay quite motionless at his side. He complained of pain throughout the arms and hands, which were extremely tender. The tendon reflexes were barely obtainable. The arms and a band across the chest from clavicle to the third rib in front, and from the seventh cervical spine to the third dorsal posteriorly showed a very marked degree of hypesthesia, but no anes-

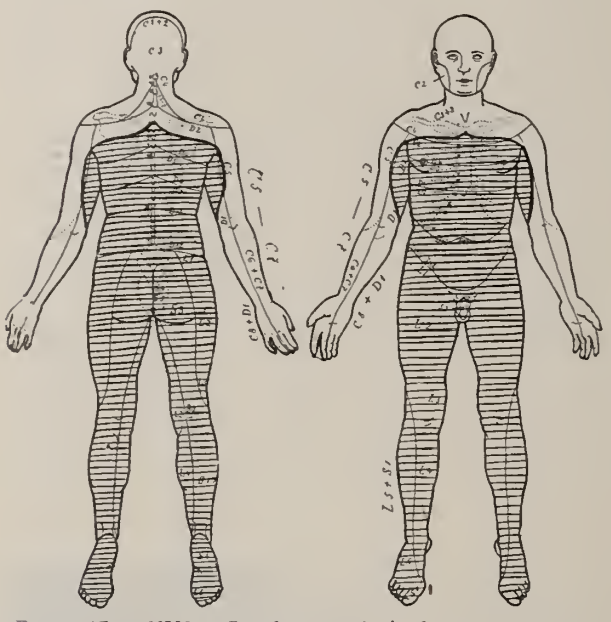

Fig. 5 (Case VIII).—Complete anesthesia from transverse myelitis; lesion at the first thoracic vertebra.

thesia. X ray examination was negative, and surgical exploration showed the absence of fracture.

On May 28th, slight flexion in the fingers of the left hand was possible. Strength returned rapidly during the next few days. In three days he could raise the left arm from the bed and could close his hand. The numbness had disappeared, except in the band across the chest, and both here and over the arms the hypesthesia was much less marked. Reflexes in the arms were still diminished, those in the legs were normally active, and there was no Babinski sign. The superficial reflexes were also present. June 13th, he was able to feed himself with his left hand and could flex and extend feebly the right wrist. Feeble flexion of the fingers of this hand and feeble pronation and supination were possible. There was also slight movement in the deltoid, biceps, and triceps. The numbness persisted across the chest. By July 1st, the movements of the left arm and hand were quite lively. He could perform all movements with his right arm, but could not yet completely close that hand. The hypesthetic band across the chest became hypersensitive. Two week later, his motor recovery was practically complete; there was some weakness in the grasp of the right hand, although the hypersensitive band across the chest was still present. His wound had healed promptly and he was dicharged, fit for service.

Case IV. Concussion and hematomyelia limited to the eighth cervical segment of the spinal cord. Weakness and pain in the arms; recovery in six weeks. The patient was a muscular man of thirty-two years, wounded December 21, 1914, and admitted the following day to the service of Doctor Mignot in the American ambulance. A piece of shell had passed across the nape of the neck, producing instantaneous sharp pain in both forearms and the palms of both hands. Upon receipt of the wound he searched in vain for his point of injury; as there was no pain in his neck his attention was not called to the wound itself. He was able to remove his sack from his back, but great weakness in both arms ensued, so that he could lift them with great difficulty. He concluded, therefore, that he had been wounded in the shoulders.

At the time of admission he was still having pain in both forearms and in the palms of both hands. The arms felt heavy, but he could move them awkwardly. He could not perform dexterous movements with his fingers and was unable to write because the pen fell from his grasp. The fingers felt cold, and there was a numbness in the ulnar border of both hands. A large, gaping, furrowed wound extended almost across the base of the neck posteriorly, passing between the sixth and seventh cervical spinous processes. After two days the paresthesia passed from the left hand, but persisted in a diminished degree in the right. There was also weakness of the right hand grasp and of flexion of the fingers and thumbs. There was considerable tenderness on pressure of the thenar eminences and on compression of the right ulnar and median nerve trunks. In the course of a month, the wound had completely healed, although he was still having pain in the ulnar muscles just below the elbow, sufficiently severe to waken him at night. The strength in his arms gradually returned, and six weeks after receipt of his wound, he was able to write and perform other movements with his fingers requiring dexterity.

The sharply limited lesion in this case was comparable to an experimental one. The eighth cervical segment, the site of the lesion, partook in the supply of both the median and ulnar nerves, hence the symptoms referable to these nerves in both arms.

Case V. Concussion of the spinal cord and hematomyelia at the level of the fifth thoracic segment; paraplegia; recovery in three months. Patient was a vigorous man of twenty-three years, wounded September 7, 1914, by a shrapnel ball while he was on the ground upon his abdomen. He felt a sharp, girdling, cutting pain around the lower thorax, and especially in the epigastrum. He found himself unable to move his legs, but could move his toes. There was a wound to the left of the fifth dorsal spine, but no point of exit. He suffered from obstinate constipation. The legs were powerless for three weeks; he then began to move his feet, and at the end of six weeks could stand. Improvement continued slowly, so that at the end of three months he could walk unsupported. It was at this time, March, 1915, that he was admitted to Doctor Blake's service in the ambulance.

The patient showed a belt of acute hyperesthesia around

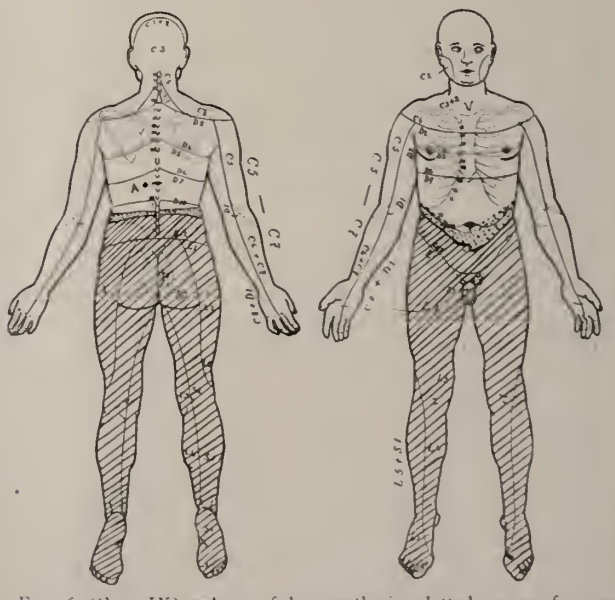

Fig. 6 (Case IX). Area of hyperesthesia, dotted; area of anesthesia to touch, pain, and temperature, diagonal lines; A, point of entry.

the thorax, 3.5 cm. wide, lying between the third and fifth intercostal spaces anteriorly, and the fifth and seventh spines posteriorly. The epigastric reflexes were absent, right abdominal was active, and left fatigued easily; the right cremasteric only was present. Both knee jerks were exaggerated and showed inexhaustible clonus of the patellæ. The ankle jerks were also exaggerated, and there was inexhaustible clonus on the left and an ex-

haustible one on the right, with double Babinski sign, more pronounced on the left. There was no Romberg sign, and the patient's gait showed no spasticity. The reflexes in the arms were active, and sensation above and below this hyperesthesia was apparently normal; the fifth and sixth dorsal spinous processes were tender on pressure. An x ray showed a round shrapnel ball lying to the left of the spinous processes between the fifth and sixth dorsal, resting upon the lamina close to the spines. The bones were apparently intact. Inasmuch as the ball was doing

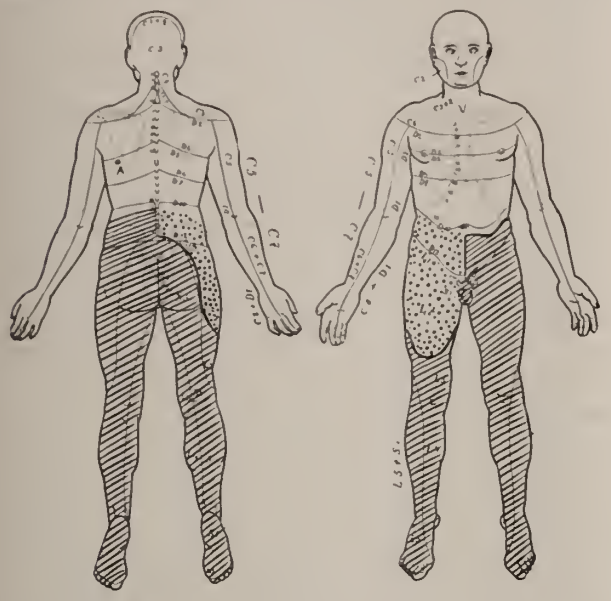

FIG. 7 (Case X).—Cord damaged at twelfth thoracic vertebra; dots show area of hyperesthesia, diagonal lines, anesthesia; A, point of entry.

no further damage, it was not removed. The belt of hyperesthesia and the clinical signs of pyramidal tract involvement were the residual evidence of the former paraplegia.

CASE VI. Concussion and inflammation of the cauda equina; flaccid paraplegia; recovery in six months. A muscular man of thirty-eight years, wounded during a charge, December 21, 1914, by a bursting shell. The right humerus was broken, and a piece of shell, the size of one's hand, struck the middle of the sacrum, driving him forward two or three metres upon his face. The legs were completely paralyzed, so that he could not rise nor even turn upon his back. He was admitted to Doctor DuBouchet's service of the American ambulance, five days later. At the time of arrival both lower extremities showed a flaccid paralysis, with absent tendon jerks and no plantar reaction. Diagonally across the upper part of the sacrum was a deep wound about twelve cm. long and three wide, involving the bone and spinal canal. A copious discharge flowed from the wound. Slight disturbance of the vesical and rectal sphincters soon disappeared. Hypesthesia of both lower extremities and some postural disturbance in the toes was present. About the middle of January, 1915, he began to move his left ankle. Within a few days flexion and extension of the knee were possible. By February he could raise his left heel from the bed. During the next month motion gradually returned in the right lower extremity, so that he could feebly flex and extend the leg and ankle, and could raise the heel from the bed. The left ankle jerk had become active, although it remained absent on the right side. There was also at this time, flexor response to plantar irritation on the left side, but no response on the right. The wound continued to discharge, and gradually granulated to a small tract about two cm. in diameter. The escaping discharge was a mixture of pus from the wound and spinal fluid. The spinal canal in the sacrum had been penetrated, but no symptoms of general meningitis developed. On January 9th and on March 13th, small sequestra were removed from the sacrum. During the succeeding month, strength in both legs returned rapidly. By the middle of June, the wound had healed and the patient was walking unsupported and felt secure and strong upon his feet. The reflexes in the right lower extremity had not returned.

CASE VII. Concussion of half the cauda equina, and hemorrhage into it. Paralysis of one lower extremity; recovery in three weeks. Patient was a well developed boy of eighteen years, wounded March 25, 1915. He felt immediate severe pain in left hip and fell, and could not move his left lower extremity. He was admitted to the service of Doctor DuBouchet in the American ambulance, March 29, 1915. The wound of entry of a rifle ball was apparent, near the right posterior superior iliac spine, and the wound of exit was in the opposite iliac crest in the midaxillary line. The fifth lumbar vertebra and the interspace below it were very tender on pressure, as was an imaginary line connecting the two wounds. The left gluteal region was also slightly tender. There was anesthesia of the left buttock from the midsacrum to below the gluteal fold. The left thigh and leg showed diminished pain sensation throughout. The left side of the scrotum and penis, and an area to the left of the median line anteriorly, extending toward the umbilicus, showed a pronounced hypesthesia to pain and anesthesia to touch. The left lower extremity showed absence of motor power, while the right was unimpaired. The tendon reflexes were not abolished, and the left cremasteric was more active than the right. After five days, he began to move his left leg, and the areas of hypesthesia, though present, were less marked. The left gluteal contraction was extremely feeble, and absence of tactile sensation over the gluteal region continued. On April 5th, the sensory disturbance was slightly less marked. He could move the left lower extremity, but it felt heavy and numb and there was no plantar response. The motor power continued to improve at a more rapid rate than sensation, and at time of discharge, ten days later, he walked quite securely and without difficulty, but still had in a mild degree the hypesthesia first observed.

CASE VIII. Contusion of the spinal cord at the level of the first thoracic segment; motor and sensory paralysis below the arms; death eight months later. The patient was wounded October 31, 1914, falling from his bicycle, and was unable to move below the shoulders. He was admitted to Doctor Blake's service in the American ambulance, November 2, 1914. He was a muscular man of thirty

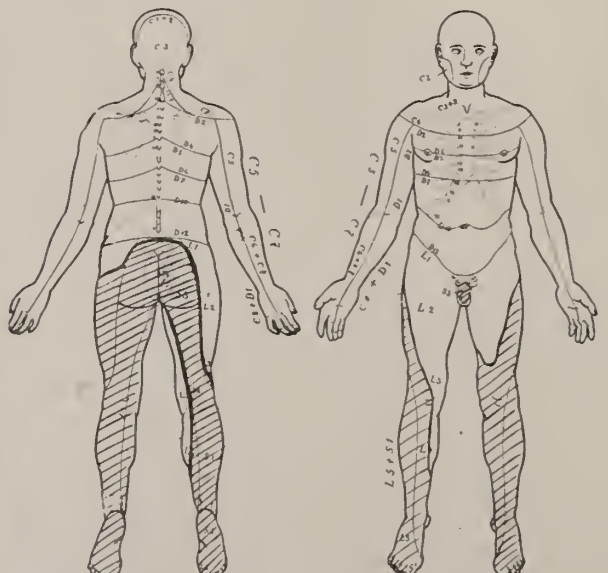

FIG. 8 (Case XII).—Anesthesia area after removal of the bullet; on admission the right lower extremity was anesthetic over same area as left; no further improvement.

years, with a bullet wound of entrance at the centre of the right scapula, and a wound of exit at the left side of the neck in the posterior triangle immediately behind the middle of the sternocleidomastoid. There was complete flaccid paralysis of both lower extremities and of the abdominal walls. The knee and ankle jerks and the epigastric, abdominal, and cremasteric reflexes were all absent. There was no plantar reflex. The reflexes in the

arms, though diminished, were present. The bladder and rectum were paralyzed. The patient was completely anesthetic to touch up to the first intercostal space anteriorly. The line of anesthesia passed symmetrically from the sternum to the shoulders, included the axillæ and the mesial aspect of the arms to a point ten cm. above the internal condyles of the humerus. Posteriorly, anesthesia extended upward to the second dorsal spine across the back, to the shoulders, and down the arms almost to the elbows. Pain sensation was absent up to a line one cm. below the limit of touch perception. Temperature sense corresponded with pain sense. Sense of pressure was absent up to five cm. below the limit of touch. There was complete absence of sense of position in the lower extremities and in the lumbar spine. The fifth cervical spine was extremely tender to pressure, and the scalp was so hypersensitive that even slight touch of the hair caused pain. X ray examination showed a perforation in the lower half of the body of the first thoracic vertebra, but no foreign body. November 23d, the patient became excitable, restless, talkative, threw his arms about in an aimless manner, and later in the day suffered from illusions, hallucinations, became confused, and passed into violent delirium which lasted two days. The spinal fluid showed no increase in pressure, no cells, no globulin excess, and reduced Fehling's solution. November 28th, he became delirious again, complained of exceedingly severe pain traveling downward from Ludwig's angle to the epigastrium and shooting off to the right. Distention of the capsules of both knees developed; this was, of course, painless.

December 2d, a violent occipital headache, which never left him, developed. The edema of the knees continued, in fact, a general edema of both lower extremities developed. The hyperesthesia of the scalp persisted. The skin became dry and desquamated in plaques and numerous bed sores formed over the sacrum and hips. Repeated catheterizations were responsible for a chronic cystitis. Complete atony of the abdominal muscles permitted constant distension. Paralysis of the intestines was nearly complete. Respiration was feeble and entirely diaphragmatic. Attacks of vomiting and respiratory disturbance occurred. He became greatly emaciated, and the skin took on a greenish yellow hue. Pain in the right hypochondrium annoyed him. On striking the sole, there would result a drawing up of the knee and foot caused by a contraction of all the muscles of the thigh and iliofemoral group; the flexors being more vigorous, predominated, so that the knee would be raised about thirty cm. from the bed. There was no contraction in the leg. The same result could be obtained by compression of the sciatic nerve, or of the muscles of the thigh or calf. About six months after admission an extremely feeble quadriceps contraction could be obtained on striking the patellar tendon, but the ankle jerks and plantar response remained absent. Without further noteworthy change, the patient died eight months after receipt of his injury from general sepsis, absorption taking place from the pelves of the kidneys.

At autopsy, the dura was found adherent to the first and second thoracic segment of the spinal cord. When removed, the other membranes were indistinguishable. The vessels were dilated and the cord was of a dirty yellow color, but of normal contour. From the eighth cervical to the second dorsal segment it was cystic and fluctuating. A slight prick at this point permitted the escape of a homogeneous yellowish fluid of gelatinous consistence. The cord collapsed and consisted only of the thickened meninges which had preserved the contour of the cord. The nervous tissue had degenerated completely in this section. The cervical cord above this area was softened, and the pia injected. Cross section showed lack of definition of the gray and white matter. The first and second thoracic roots were adherent to the dura. Below this point the gross appearance of the cord was normal.

Case IX. Section of the spinal cord and spinal roots at the eleventh thoracic vertebra; paraplegia; survival of one year at least. The patient was wounded October 29, 1914, while digging a trench. He was in full uniform, with his bayonet hanging from his belt. Following the bursting of a shell close at hand, he felt as though a sudden heavy blow had been dealt him in the lower back. He lay as he had fallen, unable to move. He experienced no pain, but there was a dull, heavy sensation in his back. He was admitted to Doctor Miniot's service in the American ambulance, October 31, 1914. The patient was a well developed man of twenty-eight years. There was a small, irregular wound at the level of the tenth dorsal spinous process and five cm. to the left of it. He presented a complete flaccid motor paralysis of the lower extremities, with paralysis of the bladder and rectum. He was anesthetic to touch, pain, and temperature over the lower extremities and the trunk up to the level of the third lumbar spine posteriorly, and a line about ten cm. below the umbilicus anteriorly. Above this was a belt of hyperesthesia some three cm. wide. Sense of position was absent in the knees and ankles. The tendon reflexes in the knees and ankles were absent. There was slight dorsal extension of the great toes on stroking the soles, also a faint Oppenheim response.

An x ray examination showed a piece of metal two cm. long and about four mm. wide, penetrating the spinal canal at the level of the tenth intervertebral disc and the eleventh vertebra.

At operation, November 14, 1914, by Dr. Richard Derby, the left lamina of the eleventh thoracic vertebra was found to be shattered and the cord completely severed. Spicules of bone that were imbedded in the cord were removed. A few fibres of the left dorsolateral tracts alone remained intact, and the cord at the site of section had already degenerated into a thick, yellowish, oily fluid. The foreign body which had caused the damage proved to be a rivet from the handle of the man's bayonet, which had been driven in with sufficient force as to cause it to lodge firmly in the body of the eleventh thoracic vertebra. It protruded into the spinal canal and was extracted with considerable difficulty. The patient recovered from the operation without noteworthy event.

By December 1st, striking the patellar tendon elicited a faint contraction in the quadriceps, the right greater than the left, associated with pain in the lumbar region. The ankle jerks were still absent, and Babinski's sign was definite on both sides. By December 14th, the knee jerks had become hyperactive, although the ankle jerks remained absent. Spasmodic contractions in the thighs and legs developed. The contractions increased in frequency and strength for about one month and then began to diminish. The intervals between periods of contractions varied from a few hours to several months. The contractions were unattended by pain, but annoyed the patient by making it difficult to maintain a sitting position in bed. The lower extremities underwent atrophy, diminishing more in the quality and tone of the muscles than in bulk. Although the knee jerks were exaggerated and Babinski's sign was present, there was no clonus. Grasping the calf would cause a contraction of the hamstring muscles.

The continued urinary incontinence apparently prevented infection of the kidneys such as developed in patients who were constantly catheterized. At any rate, he continued in a fair state of health and was alive for at least one year after he received his injuries.

This was the only one of twelve patients in whom the cord presented a complete transverse lesion, who recovered his knee jerks and showed a Babinski sign. Compared with the other patients, he showed less trophic change and experienced no pain.

Case X. Laceration of the spinal cord and spinal roots at the twelfth thoracic vertebra. Complete paraplegia; survival of seven months. Patient was a muscular subject, thirty-one years old, wounded October 6, 1914, by a rifle ball. He was lying on the ground face downward, when he felt a sudden stinging sensation in his left shoulder and a cutting sensation across the waistline. There was an absence of sensation below the waist, which made him think that his legs had been carried away. Upon seeing his legs, he tried to move them, but found it impossible. October 16th, he was admitted to the American ambulance on Doctor Migniot's service. Examination revealed a bullet wound lateral to the left scapula near the posterior axillary line, marked edema, and some ecchymosis of the skin of the back. No tenderness nor deformity of the spine was discovered. He presented a complete motor and sensory paralysis below the waistline, except an area over the anterior and lateral aspect of the right thigh, which was hyperesthetic. There was urinary and fecal retention. The level of sensory disturbance girdled the trunk at the first lumbar intervertebral space posteriorly and at a point two cm. below the umbilicus anteriorly. All reflexes were absent in the lower extremities. There was no plantar response. Light tapping of the patellar tendons produced severe pain in the lumbar region.

He suffered attacks of severe lancinating pain, beginning in both knees and extending to the waist; these necessitated morphine. An x ray examination revealed a rifle ball lying one cm. to the right of the median line, between the first and second lumbar vertebræ.

Surgical intervention was advised, and on the following day, October 18th, a left hemilaminectomy was performed by Dr. Richard Derby. The transverse process of the twelfth dorsal vertebra was shattered, the body of the first lumbar badly damaged, the dura torn, and the cord had degenerated to the consistence of an oily yellowish fluid. As the bullet was not immediately in view, no attempt was made to remove it. The patient recovered from the operation without incident, although there was, of course, no alteration in his physical condition.

Multiple bed sores soon developed, also cystitis, causing an irregular septic temperature. He became jaundiced, greatly emaciated, and suffered with distention and pain in the abdomen. An extreme degree of atrophy of the lower extremities and buttocks developed. He continued in this deplorable state until death ensued, April 21, 1915.

At autopsy the spinal cord showed a dense scar matting roots, cords, and meninges into an indistinguishable mass at the level of the twelfth dorsal vertebra. Immediately above this, the cord expanded into a fluctuating bulbous cyst. The last distinguishable and uninvolved spinal root was the ninth dorsal. Below this the roots were matted into a mass of scar tissue. Across the posterior surface of the body of the twelfth dorsal vertebra was a necrotic blackened groove. The bullet was found to the right of the second lumbar vertebra. Abscesses in both kidneys, fatty degeneration of the liver, an atrophic state of the heart, and fibrinous deposits over the pleural surfaces were present.

Case XI. Laceration of the cord and spinal roots at the twelfth thoracic vertebra; paraplegia with sharp pains in the legs; operation, section of the cord; no relief. Survival of nine months. The patient was wounded, October 29, 1914. He felt as though he had been struck in the lower part of the back with a sledge hammer. His knees gave way and he fell backward. He experienced constant pain in his knees for twenty hours, after which he was not conscious of his lower extremities. He was carried off the field immediately and arrived at the American ambulance, October 31st, and was admitted to Doctor Du Buchet's service. The patient was twenty-six years old and in excellent physical condition. There was a perforating bullet wound in the tenth intercostal space in the left scapula line. The wound of exit was a little larger, about two cm. in diameter, and was situated in the median axillary line of the opposite side at the crest of the ilium. There was a complete flaccid motor paralysis in both lower extremities; absence of tendon reflexes, no plantar response, and no cremasteric reflexes; epigastric and abdominal reflexes were present. The lower extremities, the lower part of the abdomen and buttocks, up to the fourth lumbar interspinous space, were anesthetic. The patient preserved a sense of pressure upon the testes, and light tapping upon a testicle produced a very disagreeable sensation through the lower abdomen. A radiograph showed no fracture of the spine and no foreign body.

On November 16th, he suffered lancinating pains in both knees, which became periodical, increasingly severe, and relieved only by morphine. Bed sores appeared over the heels and sacrum. November 28th, he had above the area of anesthesia an exquisitely hypersensitive band. Even a slight movement of the sheet or the stroking of a wisp of cotton caused extreme pain. Up to December 17th, it was necessary to catheterize him; there was then incontinence. There developed about this time an enormous degree of edema of the lower extremities.

During January and February, the severity of the pains in the lower extremities diminished, but recurred with increasing severity during March and April. The area of anesthesia remained unchanged and there was no return of motor power. An attack of lymphangitis in the left lower extremity, extending upward from a bed sore on the heel, occurred during March. Incontinence continued and he experienced no sensation on the passage of urine or feces. The unmitigating character of the pains in his legs and the absence of any evidence of recovery led to the decision to cut the cord above the point where there was probably an accumulation of scar tissue.

Laminectomy was performed by Dr. Harvey Cushing, on April 27th. The tenth, eleventh, and twelfth thoracic and first lumbar laminæ were removed and the dura was thoroughly exposed. There was a small strip of intraspinous fatty tissue covering the dura. Opposite the twelfth thoracic vertebra the meninges appeared normal and bulging. Opposite the twelfth thoracic and the first lumbar vertebræ, the cord and all the lower nerve roots were adherent to the dura on both sides, in fact, all the tissues in this region were densely adherent. There was also on the left side at this point an old healed tear in the dura. The spinal cord and all the nerve roots in the canal were divided and pushed back, both above and below, so that a space of one cm. remained between the cut ends. The various tissues were then closed and the patient made an uneventful recovery. It was found that the level of anesthesia on the left side had ascended to midway between the umbilicus and the groin, showing that the cord had been severed in healthy tissue.

After the operation the patient still suffered pains in the legs, and during the succeeding month was free from them only at intervals, as before. The paroxysms, in fact, seemed more severe, but there was an increase in the interval between attacks. As a matter of fact, the therapeutic hopes of the operation were not fulfilled. The patient was transferred to the Salpétrière and was reported to have died three months later.

Case XII. Contusion of the spinal cord; lesion at the third lumbar segment; paraplegia; death in ten months. The patient was wounded December 21, 1914. He heard the whistle of an approaching shell, ducked his head, but remained standing. The shell exploded about ten metres behind him. He felt a sudden hot sensation in his back, as though an electric shock had passed down both legs, fell, and was unable to move his legs. He was admitted to Doctor Du Bouchet's service in the American ambulance, December 26th. Catheterization had been necessary since the receipt of the wound, and there was incontinence of feces. The patient was thirty-six years of age, and of excellent physique. There was complete loss of power in both lower extremities, the ankle and knee jerks were absent, and no plantar response was obtainable. The cremasteric reflexes were absent; the abdominal and epigastric reflexes were preserved. There was a small reddened bed sore area on the right hip and on both heels.

Complete anesthesia to touch, pain, and temperature existed over both legs to a point a little above the knees anteriorly; from this point the anesthesia passed outward toward the great trochanters, and inward along the adductors, leaving an eliptical area of preserved sensation on the anterior surface of both thighs. Posteriorly, the lower extremities were anesthetic from the top of the sacrum down. The penis and scrotum were anesthetic. There was a small wound of entry eight cm. to the left of the median posterior line, at the level of the twelfth thoracic spine. Upon pressure the eleventh spinous process was tender.

On December 27th, Doctor Drennen exposed the eleventh and twelfth dorsal and first lumbar spinous processes. The left lamina of the first lumbar vertebra was splintered and the fragments were removed, exposing a large spread out shrapnel ball lying in the left side of the canal upon the dura. The ball was easily removed. The dura was slit for one inch, exposing the cord, which was of normal appearance as to contour, size, and color. There was no hemorrhage, congestion, or edema. The patient recovered from the operation without serious reaction. By January 10th, he could contract the adductor muscles feebly. Five days later, he began to have involuntary spasms in the sartorius and adductor muscles of both sides. He became incontinent of urine on January 20th, having suffered from retention up to this time, and on January 31st, he began to have periodical lightning pains in both legs. Sense of motion in the right ankle and great toe returned, and an increased area of sensation upon the right side. The inner aspect of the right leg almost to the ankle recovered sensation. There was no other improvement, in fact, atrophy supervened in both legs and his tabeslike pains became increasingly severe. Lumbar puncture, performed on March 16th, did very little to relieve them; fluid showed no increased pressure, was of a clear yellow color, without cells, but contained marked globulin excess. The patient acquired cystitis and ultimately died after ten months from sepsis due to absorption from the pelves of the kidneys. During this period there was no increase in

sensation, and the motor power in the lower extremities was limited to the pectineus, the iliopsoas group, and the adductors.

CONCLUSIONS.

From a study of the foregoing and similar cases of shell and bullet wounds of the spinal cord, the following conclusions may be drawn:

1. *Diagnosis.* The initial physical signs of contusion and concussion of the spinal cord may be identical, but an interval of twenty-four hours is usually sufficient to differentiate the conditions.

Concussion is usually characterized by more profound motor than sensory paralysis.

Contusion causes a parallel degree of sensory and motor paralysis.

Concussion is attended by numbness and tingling in the extremities affected.

Contusion of the caudal segments of spinal cord involving the cauda equina is associated with lancinating tabetic pains in the lower extremities.

A stereoscopic röntgenographic examination of the spine is valuable, almost essential.

When the lesion includes the cord and spinal roots, the symptoms are referable to the segment of the cord which give off the highest spinal root involved. The anatomical lesion is therefore several segments below the physiological.

When the cord only is involved, the anatomical and physiological lesions are identically situated.

2. *Prognosis.* Concussion with hematomyelia frequently results from the missile striking against the vertebra. Paralysis caused by this condition usually recovers rapidly and entirely.

Contusion or laceration of the spinal cord by actual contact with the missile, does not usually improve and is eventually fatal. Bedsores, cystitis, pyelonephritis, and sepsis is the usual course of the disease.

A patient with contusion of the cervical region of the spinal cord seldom survives long enough to reach the base hospital.

THE TREATMENT OF INFANTILE PARALYSIS.*

Based on the Recent Epidemic.

By Henry W. Frauenthal, M. D., F. A. C. S.,
New York,
Medical Director, Hospital for Deformities and Joint Diseases.

> "Infantile paralysis is an infectious and communicable disease, which is caused by the invasions of the central nervous organs, the spinal cord and brain, of a minute, filterable microorganism which has now been secured in artificial culture, and as such is distinctly visible under the higher powers of the microscope."

LOCATION OF THE MICROORGANISM OR VIRUS.

"The virus of infantile paralysis, as the microorganism causing it is termed, exists constantly in the central nervous organs and upon the mucous membrane of the nose and throat and intestines in persons suffering from the disease; it occurs less frequently in the other internal organs, and it has not been detected in the general circulating blood of patients." (Flexner.)

The purpose of this paper is to bring to attention what has been learned in the present epidemic of the treatment of infantile paralysis in the acute stage covering the first two weeks, and in the chronic stage covering a period of five to fifteen years from the beginning of treatment to such a time as operative procedures may be undertaken.

In a conversation with Dr. Haven Emerson at the Hospital for Deformities and Joint Diseases, on September 6, 1916, he informed me that in the various treatments carried on in the four city hospitals, consisting of internal administration of hexamethylenamine, intraspinal injections of adrenaline, as recommended by Dr. S. J. Meltzer, of the Rockefeller Institute, injection of immunizing serum from patients having had the disease, and injection of normal serum of healthy persons, there were numerically as many deaths, as many perfect recoveries, and as many cases of paralysis.

Hence, from the present methods of treatment in the acute stage, no apparent advantage exists from any line of treatment further than the fact that in cases where competent diagnosticians detect the disease in its incipiency, when paralysis threatens, and are able to recognize anterior poliomyelitis immediately, the disease has been checked and paralysis averted by the injection of immunizing serum obtained from persons who have already had the disease. Very successful, satisfactory results in this work have been reported by Dr. George Draper, of the Presbyterian Hospital, and by the observers in the health department.

The question as to when to begin the physical methods of treatment and protective methods to prevent contraction deformities, differs in the minds of most of the physicians at present engaged in this treatment. Some doctors apply braces and others apply plaster of Paris to prevent these contraction deformities. I wish to repeat here what I have said in previous publications of the irrational use of plaster for this purpose. A brace should be used which can be removed for the bath, light massage, etc. If a limb is confined in a solid plaster of Paris cast we add atrophy produced by the confinement (similar to the atrophy which occurs in a fractured extremity when encased in plaster), to the existing atrophy of the disease.

In addition to this, I have seen very bad sloughs produced in the application of plaster by incompetent assistants, owing to the imperfect way in which the plaster splint was applied. I wish most emphatically to state that plaster casts should never be used in infantile paralysis. Aluminum splints, which are inexpensive, are the most perfect type of protective splint and can be removed daily for such physical treatment as may be desired.

The time to begin treatment is in the second week. A good deal of pain that is due to the neuritis can be relieved by immersion in a warm bath. Much damage has been done to the nervous system and the health of children by administering morphine for these pains. I have seen in consultation several cases where this has been continued for a period of from three to five weeks, making

*Read at the annual meeting of the American Electrotherapeutic Association, September 12, 13, 14, 1916.

the child a nervous wreck. A substitute for the bath in bed is an electric light bath, which acts as an analgesic in many types of toxic pains. This is done by exposing the extremities to white light, and then turning the child on the abdomen, producing hyperemia in the spine with the light. This hyperemia, which is followed by secondary anemia, relieves the congestion in the cord.

Before continuing to describe the subacute condition, I wish to make an appeal for the investigation of high frequency currents, x ray, and radium for their powers in inhibiting bacterial growth and the destruction of the toxins in this disease. In my previous papers I have emphasized the value of the high frequency current, since which time several other authors have noted the efficiency of this current for the destruction of bacteria and their toxins. "The results of this series of experiments make it apparently certain that the reproductive power of bacteria can be destroyed by exposure to the ultraviolet rays" (1). M. Maurice Renaud (Académie de sciences, July 28, 1913) says that high frequency currents destroy bacteria and their toxins.

FIG. 1.—Showing cramping of toes and foot by plaster of Paris cast left on for eight weeks.

I have personally observed in cases taken from the home to the hospital and treated with high frequency currents for ten minutes along the spine, every three hours for three days, an arrest in the progress of the paralysis, and a decided recovery from the condition existing when the patient was first brought to the hospital. I regret exceedingly that no attempt has been made in the city hospitals to use any type of physical therapeutics such as high frequency currents, x ray, or radium as an inhibiting force to destroy the bacteria of infantile paralysis and their toxins in the acute stage of the disease, and it is certainly within their sphere to take advantage of any opportunity in acute infantile paralysis to test these physical agents. Light massage and baths should be continued while the patient is in quarantine.

At the Hospital for Deformities and Joint Diseases, the following plan of treatment is carried out and has been kept up for the past ten years:

Electric treatment. After an extended review of medical literature, I have failed to find any detailed descriptive method of the use of electricity and massage in infantile paralysis, so I shall describe what I consider the method yielding the best results. When should electric treatment begin, and what form of current should we use? Many writers advise waiting from four to eight weeks after the temperature becomes normal before doing anything in the way of treatment. According to the rules of the Department of Health of the City of New York, eight weeks' quarantine is required; in New Jersey, six weeks is required and in Pennsylvania, four weeks. I have found that we obtain the best results by beginning when paralysis appears and even before the temperature is normal.

I give to the muscles involved a sinusoidal current, alternating with a combined galvanic and faradic current that contracts seventy-two times to a minute, synchronous with the heart beat, and I regard this as an aid in the effect. It is known that contraction of the muscle can be obtained by the will; hence, this is a valuable means of retaining and developing the muscle fibre until it comes under the guidance of the mind.

Although many differences of opinion prevail as to the application of the sponge electrodes, I am in the habit of applying them at the origin and insertion of the muscle or muscle groups involved, always laying stress on the importance of approximating the origin and insertion of the muscle as nearly as possible. For instance, in treating the peroneal group, these muscles being most frequently involved, one sponge is placed over the middle third of the outer side of the fibula, the foot flexed as much above a right angle as possible and the other sponge applied over the insertion of these muscles on the outer side of the foot. In this way, the bellies of the muscles are relaxed and a contraction is made more easy.

I believe that much unnecessary stress has been laid on the reaction of degeneration, and I wish to prove, from a large practical experience, how deceptive it may be. It is said that a failure to obtain a muscle contraction by a galvanic or faradic current is an evidence of degeneration of the muscle fibre, and that no improvement can be looked for in this paralyzed condition in the future. Do we fail to obtain a contraction in most cases? No. We find that the cutaneous surface will not tolerate the pain of the current, and we must desist before contraction takes place, for most of the cases occur in children under five years of age who see no reason for enduring pain. This is even true in other cases when the age of the patient and his cutaneous toleration are greater; the strong current may give no reaction and still reappearance of function may occur. Hoffa said that the only way to determine the character of the muscle was to operate and cut down on the muscle, examining the nature of the muscle fibre to determine its condition.

The strength of the currents should be the weakest that will produce a contraction, and it is never to be used after contraction of the muscle ceases, nor longer than from two to three minutes on any particular muscle group, or from six to twelve minutes on the body at one séance. If this method is followed, the child will not cry from pain, or have its nervous sys-

FIG. 2.—Showing pressure sores produced by plaster of Paris cast on anterior surface of ankle.

tem upset by too long continued electric treatment. I regret to state that the worst results seen by me have been in children of physicians who have had an excess of treatment; that is, electricity given from half an hour to an hour daily has inhibited the recovery and eaten up, as it were, all nature's element of repair.

Massage. Dr. Benjamin Lee says: "In the essential paralysis of infancy, truly wonderful results are obtained by massage." Massage treatment should be begun the moment the acute inflammatory symptoms have disappeared and be continued daily in the face of seemingly absolute ineffectiveness, for weeks and even months. Cases in which no improvement can be detected for long periods, often suddenly begin to improve and progress with great rapidity.

The effect of massage may be classified as 1, mechanical; 2, reflex; 3, thermal, and 4, electrical.

1. The mechanical effects are by far the most important, but the others should not be overlooked or forgotten. They consist of the interchanging of cell contents under the influence of alternate pressure and relaxation; a quickened movement of the blood in the capillaries, especially in the muscular tissues; increased activity in the movement of the areolar fluid; acceleration of the currents of both blood and lymph in the respective channels.

2. The reflex, or purely nervous effects of massage are obtained by light stroking and percussion. The former produces results which can be explained only on the supposition that it acts as a stimulant to the reflex system of nerves, the force used not being sufficient to account for any change on the mechanical theory.

3. The thermal effects of massage and movements are almost too apparent to need scientific demonstration; everyone is familiar with the fact that both muscular contraction in the form of ordinary exercise and simple friction develop bodily heat to a striking degree. Dr. Weir Mitchell, in his essay on *Fat, Blood, and How to Obtain Them*, notes (what has been observed by many others) that he had frequently seen the strangely cold limbs of children suffering with infantile paralysis gain from 6° to 10° F., during massage.

4. The remarkable effect of massage results partly from the development of surface heat, partly from the surface friction, partly from the attrition of the muscular fibres and cells, and partly from the nerve stimulation and chemical action. Graham observes that muscles give a much more ready, vigorous, and agreeable response to the will and to the faradic current after massage than they did before.

A child suffering from infantile paralysis was introduced, the affected limb having a surface temperature of 70° F. The poles of a battery were applied, and eleven milliampères were required to produce muscular contraction. The limb was then massaged and the temperature was found to have risen to 95° F. The poles being applied at the same points, contractions followed the employment of only five milliampères. It is evident, therefore, that massage diminishes the resistance of the tissues to the electrical current and increases the electrical contractibility of the muscles.

As some men prominent in orthopedics and neurology have condemned the use of electricity and massage, I have taken one of the most recent articles illustrative of this side of the subject, by Dr. Henry Ling Taylor: "The conventional treatment by electricity and massage is completely ineffectual." Further to support this position, he continues: "This was publicly acknowledged by Dr. B. Sachs, of New York, a distinguished neurologist, and chairman of the Collective Investigation Committee of the New York epidemic of 1907, at the Congress of American Physicians and Surgeons, at Washington, May 10, 1910. He spoke of electricity and massage in these words: 'I consider that the time given to electricity and massage, in these cases, is wasted. I cannot see that these methods do any definite good.'"

It is true that Doctor Sachs made the preceding

Fig. 3.—The aluminum removable foot splint to prevent foot drop; light and clean.

statement in May, 1910, as I was present at the time. But five months later, on October 24, 1910, at the New York Academy of Medicine, Doctor Sachs, in discussing this subject, spoke of electricity and massage in the highest terms, thus showing that a man of high standing, from a later and more comprehensive knowledge of the subject, completely changed his views of the value of electricity—a striking illustration of the old adage, "Wise men change their minds."

Doctor Taylor's unconscious accord with this view is shown on the next page of his own article where he speaks in the highest terms of vibration which the overtreatment hampered the progress of recovery. Fifteen to twenty minutes daily is sufficiently long to administer treatment.

The abuse of treatment is found in prolonged massage. Children who receive an hour or more of treatment daily cannot improve in the face of such a physical tax. I have seen many cases in which the overtreatment hampered the progress of recovery. Fifteen to twenty minutes daily is sufficiently long to administer treatment.

Hydrotherapeutics. The use of the bath, where-

by we may float the limbs and aid motion, is a valuable adjunct to treatment. I wish to draw attention to the value of immersion of the affected limb in warm water from 95° to 102° F., for twenty minutes each night, when we find that the sixty-two and a half pounds of pressure of the water, when removed to the atmospheric pressure of fifteen pounds to the square inch, results in a dilatation which, together with the heat absorbed, produces an effect on the trophic centres and improves the temperature and growth of the limb. The paralyzed limb retains this heat for hours.

Muscle education. Finally, I wish to call attention to a class of active and passive exercises done before a mirror, having the patient concentrate his mind on the affected muscles. When the origin and insertion cannot be approximated by an effort of the will, the attendant aids in the effort.

After a time, however, it is found that the motion may be brought under control of the will. It is known that when motion is guided by mental concentration, the sulci in the gray convolutions in the brain, presiding over this motor area, are increased as well as the calibre of the nerve going from the cortex to the periphery. It has been demonstrated by Anderson, of Yale, and others that when a person is securely placed on a body balance and concentrates his mind on an extremity, the hyperemia thus produced tips the body balance in the direction of the limb.

A moment's thought makes clear the fact that the nerve efficiency or nerve control, as displayed by the gyrations of the Nautch dancer, can be developed by any person in any set of muscles if a proper effort is made. The stimulus transmitted from the brain to the periphery depends on the calibre of the conducting nerves, as the diameter of copper wire regulates the volume of electric current capable of transmission. We must realize that the concentration of the mind on the muscular effort not only initiates the movements, but also sends blood to the controlling nerve centres, producing growth and development in the conducting filaments.

In this treatment of infantile paralysis, in addition to the application of massage and treatment by galvanic, faradic, sinusoidal, and high frequency current, in children over three years of age a course of muscle education before a mirror is added, which I regard as one of the most important, because recovery is best brought about by the action of the will, influencing action after massage and electricity have brought the muscle under the control of the mind.

The muscles most frequently involved in infantile paralysis are the peroneal group, and the plan of exercising one set of muscles can be utilized in another set of muscles involved. Placing the child in a chair before the mirror in a comfortable position, I first approximate the origin and insertion of this muscle group by bringing the foot up to a right angle with the leg, and then urge the child to aid in bringing up the little toe side of the foot through an arc of about 30°. If the muscle contraction is such that the child cannot do this alone, the instructor places one hand on the knee to keep the leg in position, and places the other hand under the foot, which greatly aids the efforts of the child to produce the required contraction. This should be repeated several times, but not to the point of overtiring the weakened muscles. Each set of muscles should be contracted in a similar manner. If the motion cannot be brought about, the mental effort should still be made for the attainment of this action.

To emphasize how efficient this method is, I wish to state that through this, combined with other treatment, I have been able to show at medical meetings, practically cured, some forty-three patients who were unable to walk for periods extending from nine months to four years, although they had received some form of treatment during that time by other physicians and had been referred to the Hospital for Deformities and Joint Diseases by such able observers as Kerley, Koplik, Mandl, and many others.

It has been learned from necropsy that when areas in the brain have been destroyed by tumor or cysts, the function for this area has continued, and by the decussation of the nerves other areas in the brain have taken up the function. I am of the opinion that in cases in which recovery has taken place in paralysis, after a few years, the motor conduction from the brain to the periphery has been carried on through other motor tracts in a new circuit, passing around the damaged area in the cord.

THE TREATMENT OF INFANTILE PARALYSIS.*

By Frank E. Peckham, M. D.,
Providence, R. I.

Infantile paralysis has made serious inroads in this country and much study has been given to it. Clinically, it is usually easy of recognition, but in the early stages it may be difficult, and indeed diagnosis may be impossible until paralysis is actually in evidence. It should be unnecessary at this time to go over the clinical picture of an acute infantile paralysis as so much has recently been written and, as far as this paper is concerned, the diagnosis will be considered as having been made.

Thus far, the treatment leaves much to be desired, and any method which offers positive assistance should be thoroughly known and used. For any logical treatment to be instituted there must be a definite idea as to the pathology, and also as to general physiological principles. According to all investigators, including Flexner, there is present in the early stages a hyperemia of the cord and meninges, the vessels are all congested, and the cerebrospinal axis is edematous. "Any inflammatory focus is surrounded at the periphery by zones of hyperemia, exudation, and edema." (Meltzer.) "In an inflammation we have to distinguish between the centre which represents the main inflammatory focus, and the surrounding area, consisting of zones of cellular infiltration, active hyperemia, and edema. In the centre the original

*Read at the annual meeting of the American Electrotherapeutic Association, New York, September 12, 13, 14, 1916.

tissue may be destroyed and when a healing process takes place it is accomplished by filling up the gap with connective tissue." (Meltzer.) In the earliest stages there is little increase of cerebrospinal fluid; later, however, there is an increase in the amount. The infection of the disease exists in this fluid which infiltrates the tissues and fills the spinal canal. In this hyperemic condition of the cord, the cellular exudate forms a sheath around the vessels and nerves at their exits, and this nerve pressure is what produces the pain along the nerve trunks in the limbs. (Neustadter.) The pressure of the zones of hyperemia, cellular infiltration, and edema may produce mechanically the symptoms in an acute poliomyelitis. In extremely severe cases, where profound paralysis of the whole body musculature seems to make death inevitable, it is not uncommon to see such a case terminate in almost, if not quite complete recovery, without special treatment. It is evident that such paralysis cannot be due to actual death of central nerve cells or recovery could not take place. What more logical than to consider it due to mechanical pressure as above described, and that with the subsidence of the hyperemia and infiltration and the consequent pressure, the symptoms should disappear? This is also demonstrated in cases of lumbar puncture when the sudden withdrawal of the fluid, thus removing the pressure, results in immediate alleviation of symptoms. The early refilling, however, causes their prompt return. This process which causes infiltration, exudation, and edema, is a reversible one, according to Meltzer, who has used adrenaline with repeated injections to relieve the pressure and thinks favorably of it. It may be possible to accomplish this in a more physiological way, and, if more physiological, it must of necessity be more permanent.

An increasing number of men are becoming familiar with the use of the static wave current to dissipate the infiltrations and edema in various parts of the body. I think we are indebted to Doctor Snow for first using it in the infantile paralysis cases. The first report with which I am familiar was in the *Journal of Advanced Therapeutics* for October, 1912. It is in accordance with this method that I had an opportunity of treating three cases a few months ago which I wish to report.

Case I. Girl, five years of age, had a sudden attack in the afternoon of September 25, 1915. There were nausea and vomiting, loss of appetite, and some fever. Four days later, she complained of pain in the left leg, severe enough to keep her awake at night. On October 2nd, the seventh day, the child was brought to my office for treatment. At this time, there was still some fever, and the pain in the leg was keeping her awake at night. Walking was possible, but with the left leg hyperextended. There was a half inch atrophy of the left calf, and both patella reflexes were absent. Treatment consisted of the static wave current applied over the lumbar region of the spine for twenty minutes. The 500 c. p. lamp with the blue screen was used over the leg muscles and over the lumbar region of the spine. Following this treatment, there was entire absence of pain and tenderness in the muscles, consequently vibration was applied and this was followed by gymnastic movements. The child was regularly brought three times weekly for treatment. There was immediate relief of symptoms, and on October 11th, after four treatments, the pain had disappeared completely. On November 8th, walking was possible without hyperextension of the knee, both patella reflexes were normal, and the muscular atrophy had completely disappeared. Treatment was continued for a while longer to be on the safe side.

Case II. A boy, aged five years. The acute attack occurred about two weeks before he was brought to my office. The boy had been in bed with fever, and when he got up the legs gave way under him. In this case the patellar reflexes were very much exaggerated. The first treatment was given November 2, 1915, and consisted, as before, of the wave current applied to the lumbar region of the spine. The 500 c. p. lamp over the muscles of the legs, as well as the lumbar region of the spine, was followed by vibration of the muscles and then gymnastic movements. After two treatments the knee jerks were less exaggerated and appetite and sleep were improved. Sixteen days later, the boy was running about as before.

Case III. A boy, two and a quarter years of age. The onset, with an acute attack of fever and pain in the legs, occurred about three weeks before he was brought to my office. About six days before, the right leg had given way. Examination showed that the tibialis anticus and extensor group of muscles were completely powerless, and both patella reflexes were absent. The first treatment, on November 5, 1915, was exactly the same as in the other cases. After two treatments, the pain was gone and there was no more crying. On December 13th, the baby began to move the toes. On December 27th, he could extend all the toes, and both patella reflexes were present. The father ceased attendance in January; the result was not quite perfect, but the parents thought the baby was all right.

Although only three cases are reported, I feel that the treatment is logical and physiological and should be given in the earliest stages; if the infiltration and edema can be dissipated at that time, much damage may be avoided.

In patients acutely sick great care must be taken to prevent overstretching of the affected muscles. Personally, I feel that this should be done by braces to be removed for treatment, which it is possible now to begin much earlier than formerly when the patients are so situated that light and vibration may be applied as already described. The splinting keeps the strong muscles stretched out and contractures are prevented. When the muscles have been exposed to the light and thus freed from all pain, manipulation may well be employed. If a limb is held by the removable splints in a position in which the muscles are evenly balanced, the strong muscle will contract just as far as the splint will permit. This means that its elasticity beyond that point is lost. Later, when the splint is removed, this muscle will prevent passive motion beyond that fixed point. If by exposure to light, manipulations have been rendered possible, and the strong muscles not only prevented from contracting, but their elasticity also preserved, when the apparently paralyzed muscles begin to regain power it will be seen at once what a tremendous advantage these methods of treatment possess. Even if a proper serum becomes an established fact, the treatment still will be to care for the muscles so that deformity may be prevented, thus reducing surgical operations such as tenotomies, etc., for the correction of deformities, to a minimum.

In the ordinary cases it is not difficult to ascertain very early what muscle or group of muscles are to be affected. As soon as it is time (which by the methods of treatment described is now much earlier than formerly) work may be instituted upon these muscles. The method which I have used for many years is, first, to expose the weakened or

paralyzed muscles to the 500 c. p. lamp for twenty minutes (the light being screened with blue glass). The light thoroughly applied heats and stimulates the tissues, and fresh red blood is thus brought to the exposed area. The blue light is an anesthetic, which causes the pain to disappear. Immediately following the exposure to light, vibration may be applied, thus increasing the flow of this flesh influx of blood and also stimulating the nerve supply. The conditions are now ideal for active muscular efforts which, everyone agrees, are of the greatest value.

It is my belief that these methods give as good results as are possible to obtain in a given case. In the neglected cases, especially in those where the weakened muscles have been pulled around by the strong ones it has frequently been found, after tenotomy has been done and deformity corrected, that the stretched out and supposedly paralyzed muscles respond very promptly to the above outlined treatment. This restoration may be obtained even years after the acute attack.

It will be observed that I have not made use of electricity in restoring muscular power, but have confined myself to the 500 c. p. lamp, vibration, and active gymnastic work. In common with most orthopedic men, I had considered that the electrical stimulation of the muscles had very little, if any value. Last winter, however, in Doctor Snow's office, I saw a girl about sixteen years of age who in earlier life had an attack of poliomyelitis resulting in paralysis of the trunk muscles and a consequent scoliosis. When I saw her, the muscles had begun to respond to the sinusoidal current, thus convincing me that results may be obtained in more than one way. Whatever physical, mechanical, or electrical methods may be used, I feel and feel strongly that gymnastic exercises, with and without resistance, are of the very greatest importance and should never be neglected.

If these methods of treatment were made use of from the very beginning, I believe there would be more perfect recoveries and, in consequence, fewer cases requiring braces and operative procedures. With braces and operations I shall deal only in a general way.

As the cases now present themselves, after the epidemic in New York and elsewhere, treatment has been nil. Many parents have been told that "nothing can be done," and I presume that the practitioner meant that as yet there was no specific serum. Let us consider for a moment what would happen if we really had a serum. In the first place, it would have to be used within the first eighteen or twenty hours of the infection. In only a few cases would the diagnosis be certain so early, which means that most of the cases would be about where they are now as far as treatment is concerned. When these patients are ready to walk, braces may be necessary to support the limbs until usage makes the weak muscles strong. Gradually, then, the amount of bracing may be reduced. If the methods of treatment above advocated are persistently used, great improvement may be expected.

The operative treatment comes last of all and includes such procedures as arthrodesis, silk ligaments, astragalectomy, and tendon work, either the fixation or transference or both. The great trouble with all of these operations is that too much has been expected and consequently there has been some disappointment. They all have a value, however, but should only be done by men who are familiar with such work and by those especially who appreciate the functional value of muscles when placed in new positions. This paper was written to place emphasis upon the physiotherapeutic modalities, especially when used in the acute stage.

266 Benefit Street.

THE SPEEDY CURE OF TUBERCULOSIS.

Presidential Address Delivered Before the American Electrotherapeutic Association, New York, September 12, 1916.

By J. D. Gibson, M. D.,
Denver.

Several years ago, in passing along the *Graben*, a street in old Vienna, my attention was attracted to a queer, yet beautiful monument. On inquiry I learned that this beautiful monument was dedicated as a thanks offering to Almighty God, for the disappearance or cessation of the black plague, some three or four hundred years ago. Later, I never passed this structure without feeling thankful that I lived in a better day, and, as I mused, Why is it a better day?—my mind turned to Jenner, with his vaccination, like a great light illuminating the ages, also to Virchow and his illustrious pupils and contemporaries, Koch, Klebs, Creduly, von Ruch, Pasteur, Metchnikoff, Welch, von Behring, and a vast army of investigators who have intensified and increased this light, until the whole world has been illuminated and benefited, until we can scarcely realize that such a thing as the black plague ever existed.

In our own land many of you will remember the old time scourges of our southern borders with yellow fever, when Federal and State shotgun quarantines were of common occurrence. By this means our old friends, Cochrane and Sanders, with other State health officers of the Gulf States, usually managed to stamp out and control the epidemics until Jack Frost came to their relief.

But now of late years, since Finlay and General Gorgas have cleaned up Havana and Cuba, and Gorgas has succeeded in making Panama almost as safe from yellow fever and malaria as New York city, we hear less of the shotgun quarantine, and trust it has passed away forever.

Before the discovery of vaccination by Jenner, not only were there thousands of deaths every year from variola, but it is stated that eight out of every ten persons met on the streets of London had their faces pitted from smallpox. Today, owing to vaccination and government control, there are scarcely any deaths from smallpox, and there is not one person in a thousand that we meet upon our streets whose face is pitted by smallpox.

Variola is not the only disease brought and kept under control by our health boards. Scarlet fever

and diphtheria, both old time terrors to doting parents, have been largely put in the background and are no longer dreaded scourges of humanity, thanks to the great researches of modern medical men.

The great predominating fact that stands out before us in controlling these plagues of contagious and infectious disease, is the support that all enlightened and civilized governments have given the medical world. They have developed step by step, the knowledge of the natural history and cause of disease, and aided in developing the great fields of preventive medicine. Without government aid Finlay never could have cleaned up Cuba and freed Havana from yellow fever, although he sacrificed his own life in doing so. Gorgas could not have cleaned up Panama so thoroughly that he has received the thanks of the civilized world for his effective work, if the United States Government had not been his staunch supporter throughout the ordeal. So it is with measles, varicella, and many other diseases; they are kept under control simply by continued and untiring vigilance of the health departments, Federal, State, county, and municipal, all having their special functions to perform. We know they are doing it well when we compare the results of today with those of only ten or fifteen years ago.

These health boards have accomplished so much already, it is my desire to thrust a little more work upon them, and see if I cannot point out a way in which a little more light can be thrown upon the only great plague left for us at the present time, the Great White Plague.

The question is frequently asked, "Why does not the government, both Federal and State, try to do more for the control and stamping out of tuberculosis in man?" We hear the government frequently criticised for spending much money on the examination and care given to domestic animals, especially dairy herds and beef cattle, to keep them clear of tuberculosis, and yet doing little for suffering humanity. Many people fail to stop, think, and realize that every cow and hog that is segregated and killed, is killed that it may not become a carrier or a source of infection of tuberculosis to human beings; in other words, every dollar spent in caring for cattle is spent in an effort to benefit humanity.

The government, you must remember, has never had any more specific and certain method of cure of tuberculosis than any of the regular physicians; therefore, it has never had any agent or method that was certain and definite enough to justify it to go to extremes and great expense for its promulgation. When the National, State, and city governments find a remedy or agent that will control, cure, or aid in stamping out tuberculosis of all kinds and stages, I predict it will aid and develop this work just as quickly and effectively as it has done in vaccination for variola, and antitoxin for diphtheria.

Tuberculosis in all its combined forms is the great plague of the age. In our own land there is a continual wending of 200,000 funeral corteges from homes to cemeteries every year. Think of the misery, suffering, and heart aches in those 200,000 funeral processions; the widows, widowers, parents rendered childless in their old age, and orphans! Think of the changes wrought in the destiny of a family by the empty chair and vacant fireside, as pale death continues to invade equally the palace of the rich and the cottage of the poor. Think of the economic loss to the State and relatives as this vast army of youth, young manhood and womanhood, is hurried on to an untimely end. This 200,000 dead are those whom all "chasing" and treatments have failed to save, no account being taken of the hundreds of thousands who fight the great fight and win every year. Shall this cortege of 200,000, with its ocean of tears and woe, go on forever? I say No!

Two years ago at Battle Creek, I read a paper before this association, in which I made the assertion that with the present light before us, it would be possible to banish tuberculosis as an important factor in vital statistics in ten years' time. Two of those ten years have passed, and I want to say that by plans I bring you today, the death rate from tuberculosis can be made probably less in the remaining eight years in the United States than it is from variola; or the 200,000 funerals can be cut to less than 20,000 yearly. Is not the saving of 180,000 lives of our neighbors, relatives, and friends yearly, enough to stir the red blood in the veins of any living man? This then, is my excuse for this discourse, and I come before you as one with authority, the authority of the treatment of nearly 1,000 cases, and of many years of experience, with the vast majority of patients treated now living, who can testify to the results.

I am not satisfied with making practical cures of more than ninety per cent. of all cases, all stages, and complications of pulmonary tuberculosis as I am making at the present time, which ratio in itself would save 180,000 of the 200,000 funerals, but we can, and must, surpass this record. I think in eight years more we can create conditions that will make death from pulmonary tuberculosis a great rarity.

The National Association for the Study and Prevention of Tuberculosis has accomplished a great work. It has taught the masses of common people the manner and cause of contagion in tuberculosis, and has taught them to fumigate rooms and dispose of the sputum in a sanitary manner. They have insisted upon outdoor life until it has become popular throughout the entire land, have established tuberculosis camps and hospitals all over the country, and have thereby actually caused a decrease in the death rate from tuberculosis in the last ten or fifteen years. But my plan is to get nearer the root of the condition than tuberculosis camps and hospitals and fresh air, and see if we cannot, in a few years, make the camps and hospitals for tuberculosis useless institutions.

MY PLAN.

1. Make use of the health boards of every city and county.

2. Every child in the public or other school should be examined for tuberculosis and treated, if needed, under the direction of a board of health.

3. The health board, or commissioners, should set aside and maintain a department for this special school work, known as the tuberculosis department, and the chief or manager of this department, with all assistants needed, should devote his entire time to the care, examination, and treatment of the school children. The exact records of each year's examination of every child, sick or well, should be kept and recorded properly. Every child that is tuberculous, or shows a reaction or sign of tuberculosis, should be treated by my method of treatment, and cured while it is attending school. Segregation will be unnecessary.

I say my method, because by this method, namely, "the adding of x ray for its direct and specific effect on the bacilli and the lung tissues or cells of the lungs; static electricity for its direct effect upon the heart, nervous condition, and general metabolism; and inhalations of an ozonized oil nebula for its effect on the cough, added to the ordinary dietetic, hygienic, climatic, rest, and medicinal care, as generally used in the treatment of pulmonary and other forms of tuberculosis," I have, in this present year, been able to save from death over ninety-two per cent. of all applicants, in all stages and with all complications of pulmonary and other forms of tuberculosis.

This is the method, therefore, which will, and does make this further step in the control of this great plague feasible. I believe the method which I am bringing before you this evening, and for years have been calling to your attention, is absolutely the most definite and positive remedial agent ever brought before the profession in the treatment of pulmonary tuberculosis. I maintain that by this method it is possible to eradicate and cure every case of tuberculosis in adults and children when detected in the early or prebacillary stage, and raise such an immunity in the victims, that it will be almost impossible or be exceedingly rare, at least, for them ever to manifest tuberculosis.

Now, if this is possible, do you grasp the significance? If every child can be rendered immune to tuberculosis for the remainder of its life, in a few years where can tuberculosis material be found upon which this great plague can continue to feed and flourish? Consequently, the third stage and desperate cases will soon have dropped from the earth, and death from tuberculosis will be a thing of the past.

Another point I want to touch on is this: The treatment will make ill developed and poorly nourished children grow and develop rapidly. I have seen many poorly nourished children, of tuberculous parents and families, grow and develop splendidly after this treatment, improving not only physically, but mentally as well. I predict that the ill nourished and physically weak children, when treated by this method, in a few years will rank alongside or above the untreated normal children.

4. Why should the school be supervised and managed in this manner by the health board? In the first place, the board of health could have unquestioned authority behind it. It can enforce its mandates and secure the treatment for tuberculous children just as it does vaccination, and matters of quarantine. All children can be cured, and will be, if it is made compulsory. Another reason is that few physicians will be willing to make the outlay of money needed to prepare them for this work, and spend their time to learn the method for the few local cases they are likely to treat. Nor would every doctor likely get patients enough to enable him to become proficient in the work. Nor could all the parents of these tuberculous children afford the expense of the treatment at private hands, as this treatment is expensive, and necessarily spreads over quite a length of time. Therefore, the physician in chief appointed by and under the direction of the board of health, should have sufficient room set aside in the school buildings, so that the examination of children can be made easily and conveniently. These examinations and tests should be made thoroughly, with all the approved methods of physical diagnosis. Physical examinations should be thorough and charted, and supplemented by sputum examinations when sputum can be obtained. Röntgenographs of the lungs and joints should always be made, and prints filed with other examination records. If doubt still exists, tuberculin tests should be used, and reactions carefully noted. In other words, if there is tuberculosis in the body of a child, find it. Find it if it is latent or active, and if you find it, treat it and cure it whether it is latent or active.

X ray machines of the best patterns will be needed for this work, both for diagnostic use and for giving the necessary x ray treatments. Ozone machines of approved patterns and efficiency should also be installed for the inhalations, thus procuring its tonic and cleansing effect on the bronchial tubes. Static machines will be required for the metabolic effect of these currents. These machines and apparatus should be installed by the city in sufficient numbers for the treatment of all children requiring it, and the expense of the work should be borne by the city.

Every case of tuberculosis in a child of this day and time can be detected. It is possible in every case for the doctor to be able to say with certainty and assurance, "yes" or "no" in the case of every patient, long before the bacilli can be demonstrated in the sputum. These are the cases we wish to find, pick out, and cure before the lungs proper become infected.

It is my experience, and I believe literature bears me out, that the tuberculosis of young children is usually glandular, and that most latent or incipient tuberculosis in children is in the bronchial, mediastinal, cervical, abdominal, or inguinal glands. In other words, it usually is first a glandular tuberculosis. Now this is when we wish to, and must detect the disease and treat it, because there is not a physician before me in this audience but knows that Röntgen rays will cure a tuberculous gland. That being the case, and it cannot be contradicted, in Heaven's name, why not cure it when to cure is easiest and surest, and save the child in the future for itself, its family, and the State, and also know that he will not be a carrier of tuberculosis, infecting all about him for the rest of his life?

We know that it is held by some authorities that all tuberculosis is contracted before the host is five years old, and in the majority of cases lies latent until later in life, when something happens to cause it to develop, and once more endanger life. If this theory has any truth in it, it only makes my suggestions more imperative.

The chief reason for forcing this idea for the control and cure of tuberculous children while they are in school or at the school age is, first, children respond promptly to the treatment, and almost every case can be diagnosed and located while it is in a curable stage or condition. Nearly all of these cases in children, when it is latent or active, can be detected and located while it is still glandular. Not only can the child be cured, but the general physical condition of the child can be so greatly improved in every way, that the expense will be a splendid investment for the county and State, to say nothing of the home and relatives Secondly, the economic side of the case is of great importance. If the tuberculous conditions are neglected in the child, they are not likely to develop until about puberty and afterward, when the children become wage earners and begin to assume some of the responsibilities of life. At this period, there is entailed not only the expense of treatment, loss of time, and increased danger, but loss of salaries as well. In other words, at this time it is a double edged sword, and cuts two ways, loss of salaries and much expense. While if the case is cured in childhood, all of this can be avoided; and when the child is ready for business and the active duties of life, it is equipped with health and strength, and will meet all its obligations with fearlessness and certainty. Therefore, it would prove great economy both to State and family, that these children should have been treated, and all taint of tuberculosis removed in their early life, and also that they had been taught to care for their health while in the public schools. They can receive treatment, ten to fifteen minutes every day, just as they take their mathematics and other lessons.

This work will have to be studied by the different staffs in charge, and much will be learned by their experience in the work, but I predict that in a short time the rivalry in the ratio of statistics between different cities will be so great, that excellent work will be accomplished. The specific details of this method of treatment will be given you in another paper to be read at this meeting, entitled, One Year's Work in Pulmonary Tuberculosis, so I will not tax your patience now with their rehearsal.

Thirdly, the tuberculosis staffs of these schools will become so proficient that they can be used as centres to which all the old tuberculosis cases in the surrounding communities can come and be cured, without having to travel many miles to different cities and climates, hunting up various specialists for this purpose.

I predict that in a few years this work will be done so efficiently by the staffs of these different schools, that my old claim, that it is possible to eradicate tuberculosis as a factor in the death rate in ten years, will be realized.

HEALTH INSURANCE FROM THE VIEWPOINT OF THE PHYSICIAN.*

By Ira S. Wile, M. D.,
New York.

The unnecessarily high morbidity and mortality rates existing among industrial workers suffice as a reason for the establishment of some type of insurance which will distribute the economic cost of such disabilities in a more just manner. With a general average of wages for the majority of the population below an amount sufficient to provide for an adequate standard of living, it is financially impossible for the conservation of health to be an active motive in family life. Nor is it possible for those with annual incomes under $1,200 a year to receive the most effective and satisfactory medical attention for the palliation or cure of their illnesses, without the sacrifice of self respect or independence.

In an attempt to secure a measure of relief during such disadvantageous times, many thousands of workers have united to establish voluntary forms of health insurance. By fraternal orders and by unions they have sought to secure group medical attention on a capitation basis which is insufficient to secure adequate relief. With doctors receiving one dollar a year from each member of such organizations and with fifty cents or one dollar a year added if the family is to be included, a high quality of medical service is difficult to obtain. The financial benefits which such organizations give are too frequently restricted according to the number of visits required, and to the character of service needed. The lodge doctor or the contract practitioner cannot provide the special types of service most essential for his patients. The treatments are not begun sufficiently early nor is the medical care prolonged to the time actually necessary to establish the return to health. What is of greater importance, however, is the fact that most types of voluntary insurance are prohibitive to workers most needing it, namely, the lowest paid in the industrial group and the least thrifty.

It has been estimated that in the United States for the 34,000,000 men and women in industrial life there are 13,400,000 days of illness or an average of eight and one half or nine days for each person. The Federal Commission on Industrial Relations has called attention to the fact that accidents cause practically only one seventh of the amount of destitution that results from illness.

It is almost axiomatic that disease entails poverty and poverty entails disease. Health insurance is a measure which properly developed would decrease poverty and disease, and generally raise the standard of health and living to a more civilized basis.

As far as the general proposition of health insurance is concerned it may be admitted that physicians in general are in favor of it. The medical profession recognizes that social legislation is inevitable. The experiences of foreign nations with accident insurance, health insurance, maternity insurance, old age insurance, and unemployment in-

*Read before North Atlantic Tuberculosis Conference, Newark, N. J., October 20, 1916.

surance represent distinct social advances in that the State, as a whole, thus manifests interest in the physical, mental, and moral welfare of its citizens.

Thirty-five States and Territories of this Union have enacted workmen's compensation acts which seek to make adequate provision for the victims of industrial accidents. A few States have developed insurance laws for the relief of occupational diseases. It is of the utmost importance that health insurance should be wide in its scope, reach the largest percentage of the workers, and take cognizance of the interests of the various parties concerned. This involves the recognition of the part to be played by the employee, the employer, the State and, by no means the least in importance, the medical profession through which the provisions of enactments are to be carried out.

I believe that the medical profession recognizes that the advantages of health insurance far outweigh any particular class disadvantages which, to be sure, merit its consideration. A large proportion of the population is constantly ill and for financial reasons deny themselves or are denied prompt and proper medical attention. The possibilities of more complete treatment leading to restoration of health naturally appeals to those interested in rehabilitating the physically handicapped. Under insurance provision more adequate facilities are provided for insured patients, not merely in hospitals and dispensaries and diagnostic laboratories, but in the important phases of medical and social service indicated in nursing care, the supplying of necessary appliances, convalescent care, and continued medical oversight.

My personal interest in health insurance is due to my conception of it as a recognition that health constitutes an asset of the State. The mere cure of individuals is of secondary importance to the principle that the general raising of the standards of health of a community is essential to the development of the best type of citizenship. Any system of health insurance which is regarded as merely a relief system fails to recognize its most vital function. Health assumes a financial value when the lack of it is penalized by financial payment. The greatest results from health insurance are to be achieved in the direct and indirect educational work aiming to establish conditions which permit continued healthful living, or at least remove environmental obstacles tending to wreck or undermine human existence.

Personally, I believe that the establishment of health insurance means an increased practice for the average physician. The possibilities of this have been demonstrated in the action of the English Insurance Bill, to which the profession was originally opposed, but which today has financially established itself as a measure beneficial to the entire profession.

A system of health insurance wherein the funds are to be provided by employees, employers, and State appropriations, appears to be sound, provided that adjustments are made for a decrease in the amount to be paid by employees in the lower wage scales. The economic loss to the nation, incidental to the illness of wage earners, approximates $750,000,000. This in itself is a sufficiently large sum to suggest the importance of distributing the loss in such a way that it does not fall upon those least able to bear it. Most of the illnesses of society are not due to the shortcomings and indiscretions of individuals, but are part of the responsibilities of society as a whole, and therefore society as a whole should pay its share of the economic loss. The statement of financial loss, however, fails to take cognizance of the loss of family life, the amount of anxiety, terror, poverty, continued invalidism, vagrancy, and criminal acts, which are bound up in the loss of health, enthusiasm, ambition, and potential working power incident to disease. The occupational hazards, the enforced unemployment, the unhealthful industrial environment, the economic disability due to low wages, represent factors which cannot be interpreted merely in terms of economic loss due to illness.

As a relief problem, the mere establishment of weekly benefits for illness would be a failure. The responsibility for health should be the motive force underlying rational health insurance acts. Health is to be sought, encouraged, and education to this end is to be developed in order to lessen the drain upon the financial resources of employees, employers, and the State as pooled in an insurance fund.

The Conference of State and Territorial Health Authorities with the United States Public Health Service advocated that the administration of the medical benefits be directly under governmental agents, who are to be responsible for the certification of all patients to whom cash benefits are to be paid. If this plan were adopted, it would be necessary to select such officers on some civil service basis in order that political questions might not arise to impair the efficiency of the system through the appointment of political favorites rather than capable administrators and examiners. Such officials should be upon full time service and would indeed serve as a check upon physicians seeking to increase their charges through prolonged treatment, and would relieve them of any of the embarrassments occasioned by questions of certification. It would be possible through them to seek out the incapable practitioners, those negligent, indifferent, or dishonest, with a view to removing them from whatever panel might be established.

As a general proposition, I believe that the patient should have free choice of physicians, conditioned, obviously, upon the acceptance of the patient by the physician, regardless of whether the payments are to be made upon a capitation, visitation, or salary basis. This in itself would be a distinct advantage to the community in that it would provide a stimulating reason for physicians to raise the standard of health of their patients and give the most efficient service, in order to retain their popularity among the workers served.

The hospital question is of exceedingly great importance. The establishment of health insurance would necessarily alter the type of dispensary practice, as at present organized, and would in time cause the abolishment of the free dispensary for those coming within the purview of the insurance law. Service by physicians in dispensaries would be paid for; hospitals themselves would be

better controlled and organized so as to provide the most modern equipment and diagnostic facilities for the use of physicians in the interests of the patients. Hospital units would necessarily be developed in accordance with the particular needs of communities, not with a view to providing philanthropic agencies, but for the purpose of supplying scientifically managed institutions for the reestablishment of the health of those making use of them. There would no longer be a going forth from hospitals of patients not fully recovered, but there would be opportunities afforded for convalescent care. The time spent in the hospital would be merely that necessary for restoration to sufficient health to permit of transportation to special institutions essential for the complete development of the potential power of the patient. Convalescent homes, educational homes, and special institutions would be created to return workers to industrial life capable of being economically independent, so far as their actual physical handicaps and disabilities would permit. With such a system of restoring facilities, the social health of the injured would be paramount, and ability to function normally would be regarded as an integral part of the conception of health.

In a general way, physicians would have larger practices, their fees, large or small, would be assured by virtue of the insurance fund. Their point of view would be changed from the pathological, which places a premium for them upon disease, to the more normal and rational view of payment received for the maintenance of health. The family of the injured, no longer suffering from a total wage loss incident to illness, would be able to maintain reasonable standards of living, suffer less distress from impoverished nutrition and anxiety, and would be less susceptible to tuberculosis and other communicable diseases. They would gain in confidence and moral force with the knowledge that disease itself penalized only the victim and not the whole family. This in itself would increase the standard of health in the community and decrease the amount of illness requiring attention by physicians during the period of greatest industrial activity.

In the working out of the details of a health insurance act, it is essential to secure the cooperation of the medical profession. The unpleasantness and hostile experiences in Great Britain must not be permitted to arise in this country. The most conservative physicians only ask that the medical profession have proper and adequate representation on the various committees or the boards responsible for making decisions in medical matters which may arise in connection with health insurance. They ask that on the panels of physicians every legally qualified practitioner of medicine should have the right to have his name recorded. They ask that the injured person shall have the free choice of any physician on the list or panel, subject only to the acceptance of the patient by the physician. They desire that all contracts for medical attendance and terms shall be made with associations of physicians composed of one or of several panels, to which associations all panelled physicians in those districts must belong.

Some interesting problems will arise under a compulsory insurance act providing for the free choice of an attendant, particularly when the State law permits treatment by chiropractics, various irregulars, and Christian scientists. The insurance act, however, can take cognizance only of the State laws establishing the qualifications for the practice of medicine. Inasmuch as efficient service is impliedly an aim of a law of this character, the question arises how it may be possible to obtain a specially qualified man. Under a free choice law with an open panel, it would be impossible to offer any guarantee as to the character of service to be given by the physician. The checking by salaried State medical officers might possibly suffice to decrease the panel list after a sufficient period of experience, but it is doubtful whether this would prove particularly satisfactory. Conditional examinations for the determination of panel physicians would meet with rigid opposition. For these reasons it is probable that State insurance acts would have to accept present standards of medical licensure as the only conditions for placing a doctor among the available insurance physicians.

The free choice of physician by the patient carries with it a hazard in that physicians would accept a larger number of patients than they could adequately and efficiently treat. Experience will in time determine the maximum number of patients which one physician can properly attend, but this cannot be defined until regulations have been established, making clear the character and effectiveness of the medical service which is to serve as the standard. For the successful and practical working out of an insurance act, these two facts must be established, though probably this is a matter of administrative detail which can be worked out only after the passage of a health insurance law.

If contractual relations are to be determined by local groups of physicians, it will probably be advisable in some places, industrial centres, for example, to employ salaried physicians to care for the insurance work in specific large industries. From the standpoint of a knowledge of occupational diseases, this would inure to the advantage of the insured and would not work a hardship to the physicians any more than is true at present where such practice obtains. In rural communities, it is possible that salaried medical officers might be employed to treat the insured, but this would arise only as a result of the action of the physicians themselves viewing the actual needs of the situation.

The provision for treatment by specialists, or the securing of consultation advice may demand the retention on salary of certain members of the profession; or possibly they should be paid on a limited visitation basis, in order to secure the best medical results. In the present complexity of medical sciences, it is impossible to expect from the general practitioner equal ability in various lines of medical service. The possibility of securing special attention should be made simple, in order that the physician himself may have every reason and opportunity for taking free advantage of such consultants in the interests of the patient.

Hospital arrangements will naturally vary in different sections of the community, but one provision in administration seems imperative, namely, that when hospital care is essential for the recovery of a patient, failure to take advantage of it should be

penalized by the withdrawal of cash benefits. Any hospital should be properly recompensed, whether the institution is organized by an insurance commission, local association, as a city institution, or is conducted under private auspices. The terms of such compensation will necessarily vary in different sections of the country.

From the standpoint of medical economics, as ordinarily understood, the most vital part of a health insurance act involves the discussion of the remuneration of the physician. Regardless of the fact that collections are assured and that there will be no loss for services given, the importance of the method of remuneration must not be underestimated. A capitation payment under an insurance act will still have many of the defects inherent in such methods of payment, as at present practised by lodges or fraternal orders. Visitation fees give remuneration in proportion to the actual service extended to the injured and are likely to conduce to the more careful consideration of the medical needs of the patient, but on any existent scale of fees are practically too costly for an insurance fund. If it were possible to devise a system where a capitation fund is set aside to be divided among physicians in proportion to their actual service, computed on visits made, it might be possible to secure a more equitable distribution of the fund, but this would require considerable checking in order to discover physicians seeking to increase their pro rata through needless visits. An indirect beneficial effect would result with busy physicians aiming to decrease the number of necessary visits through educating their insurance clientele in methods of hygienic living.

While it has been suggested that the occurrence of epidemics would throw an extra burden of work and cost upon physicians, it is probable that in general this would be offset by the diminished amount of work with relatively higher fees during periods when epidemics did not exist.

From the standpoint of physicians, there are obvious benefits in the increased opportunities for nursing service, maternity benefits, hospital treatment, and the furnishing of medical and surgical supplies. I believe strongly that health insurance represents a practical, just, and responsible method of distributing the economic losses incident to disease, that it gives a financial incentive for the development of higher standards of health and social welfare, and that it is a public health measure of unusual importance. I believe it to be desirable from the standpoint of the medical profession which is vitally interested in promoting the health and welfare of the industrial workers of this country. In this view, I believe, we may count upon the support of the enlightened profession, which is willing to acknowledge its responsibilities to the community and to cooperate in bringing about the social advances which are possible only through higher health standards.

230 West Ninety-seventh Street.

Treatment of Chorea Based on Etiology.—W. C. K. Berlin (*Western Medical Times*, November, 1916) is inclined to believe chorea to be an infectious disease, and says he has obtained excellent results from a streptococcus vaccine.

THE LATE DR. HENRY L. ELSNER,*

By Charles G. Stockton, M. D.,
Buffalo.

To inherit goodness, intelligence, and the love of knowledge, to have the opportunity for self development and the diligence to acquire skill, to be endowed with personal traits that win confidence, to have accomplishments that secure the approbation of fellow workers—all these combine to make an enviable character of which would be predicted a successful career. This array of qualifications was that of Dr. Henry L. Elsner, an honored member of this association, who died on February 17, 1916, deeply regretted by the medical profession and by a host of devoted friends, pupils, and patients.

Doctor Elsner was born in Syracuse, N. Y., and at his death held the chair of medicine in Syracuse University. Although only fifty-eight years of age, he was old in practice, having graduated from the College of Physicians and Surgeons at New York, in 1877. Soon after this date he became a student at Vienna and returned to his native city well qualified to begin a professional life, which was notable for its high ideals, its scholarly methods, and its adherence to the best traditions. It was only natural that Doctor Elsner should become eminent, that he should become the leader in northern New York as teacher, consultant, and practitioner; he had been president of the Medical Society of the State of New York, of his county and his city medical societies, and was an active member of many other learned societies, including the American Therapeutic Association.

He had contributed largely to literature and had but just completed his *magnum opus*, a large book on prognosis, which is likely to secure for his name enduring commendation.

Doubtless the intense application which the creation of this book required, sapped his vitality. He sought rest at Washington, but passed away unexpectedly just when he was believed to be mending.

His death was a shock to every one who knew him, especially to his colleagues in New York State.

It is a pathetic fact that his wife survived him only a single month.

436 Franklin Street.

Septic Teeth.—John S. Marshall (*California State Journal of Medicine*, November, 1916) urges that nearly all teeth with abscesses at their roots should be extracted. The dentist frequently treats these cases with the hope of curing them, that a crown or bridge may be inserted, but in most cases these diseased, septic, abscessed teeth are not amenable to treatment and would be better out of the mouth. The difficulties which surround the proper treatment and filling of the root canal of pulpless teeth are very considerable. The operation requires a great degree of technical skill and unlimited patience, so the dentist of average ability rarely succeeds in making a perfect operation of this class, a statement that has been proved by many x ray pictures.

Dietetics, Alimentation, and Metabolism

Food and Food Preparation, in Health and Disease

FOOD AND EFFICIENCY.

By Martha Tracy, M. D.,
Philadelphia,
Professor of Physiological Chemistry, Woman's Medical College, Pennsylvania.

(*Continued from page 954.*)

IV.

DAILY REQUIREMENTS OF THE HUMAN BODY.

We have now reviewed briefly the purposes of food in the animal body and have shown that normal nutrition involves an adequate supply of tissue building foods; proteins, a little carbohydrate and fat, inorganic salts, water, and minute quantities of vitamines; and of fuel foods, chiefly fats and carbohydrates, to yield the energy necessary to keep the machinery in motion.

We are prepared now to approach the obvious practical problem of what constitutes this adequate supply of food; how much tissue building material do we need each day to keep the body engine in repair, and in youth to provide for growth; and how much fuel is necessary under the varying conditions of life to keep the engine running smoothly and capable of carrying on productive work with the highest degree of efficiency?

Lavoisier once attacked this problem, and having demonstrated, in 1870, that "animals which respire are truly combustible bodies which burn and consume themselves," he put together the first primitive contrivance for measuring the oxygen consumption of a living animal.

Eighty years passed before Pettenkofer and Voit, in 1862, constructed their classical respiration calorimeter, and Voit, in 1866, began the computation of the amounts of food substances theoretically oxidized in the body, as measured by volumes of oxygen consumed, and volumes of carbon dioxide expired.

In 1885, Rubner, in Voit's laboratory, made the first accurate determinations of the heat producing value of urea and other nitrogenous substances, and established the now accepted biological figures for the heat producing or caloric value to the body of the three great classes of organic food stuffs, fats, carbohydrates, and proteins. Rubner, in 1894, constructed the first really successful calorimeter for studying the energy exchange in dogs, and Atwater, studying in Voit's laboratory at this time, returned to America with the inspiration and experience that enabled him to take up the work in this country.

In the laboratory of Wesleyan University at Middletown, Conn., in 1903-1904, was built the Atwater-Rosa-Benedict respiration calorimeter for man, in which the first experiments in human calorimetry were carried on. By means of this remarkable apparatus, a full description of which would be out of place here,[1] it was for the first time possible to measure with accuracy the amount of oxygen consumed, the amount of carbon dioxide discharged, and the amount of heat liberated by a human being during a period of several hours or even days, and under varying conditions of rest and of work. During the past twelve years more has been learned of the energy transformations, the energy metabolism, of man than during the entire period of 125 years that followed Lavoisier's discovery.

Preceding and accompanying these epoch making experiments of Atwater and Benedict, however, much valuable information was gathered from many sources, by observers who studied the problem of the food intake, and food or fuel requirement of man by methods which, though less elaborate and precise, have yielded remarkably confirmatory results.

We are now able to examine and answer this question of food requirement through the following methods:

1. We may weigh accurately the food actually eaten by a man or woman, multiply the total weight of fat, carbohydrate, and protein by the factors which represent the fuel values of these food stuffs (1 gram of protein=4 calories, 1 gram of fat=9 calories, 1 gram of carbohydrate=4 calories) and thus determine the total caloric value of the food ingested, which represents the energy, expressed as heat, which is available to that person for the period given.

2. We may from weight of protein food ingested, and weight of nitrogenous material excreted in the urine and feces, calculate the amount of nitrogenous material retained in the body to serve tissue building purposes.

3. We may determine the energy generated in the subject's body by "indirect calorimetry"; that is, we may measure, by now simplified instruments, the oxygen actually consumed and the carbon dioxide actually expired during a given period, and compute from the figures so obtained the number of calories of heat which must have been produced by the combustions which have given rise to our oxygen and carbon dioxide figures. Thus again we have estimated the number of calories, the amount of energy, available to that person during the period given.

4. We may place the subject in the now perfected respiration calorimeter and actually measure the heat given off by that body during the period of observation.

Thus we gain data in regard to both phases of our problem of food requirement. By the first and second methods we note the amount of nitrogenous or tissue building food used daily in maintaining the body in an "equilibrium of substance," and we note

[1] See *Publication No. 42*, Carnegie Institute of Washington, and the publications of Atwater and Benedict in *Bulletins of the Office of Experiment Stations*, U. S. Department of Agriculture.

by methods one, three, and four, the total amount of fuel consumed, of heat generated, of energy released during the daily activity of the body machinery. We shall discuss this total daily energy requirement first.

Before the perfection of the accurate instruments for direct and indirect calorimetry, the statistical or dietary studies furnished the chief sources of information as to the caloric value of the food available or actually used, and therefore presumed to be required by men and women under varying circumstances. Thus Neumann made careful observations of his own total daily food consumption during ten months, while pursuing his usual professional duties in the Hygienic Institute at Kiel. The energy value of his daily food, which was sufficient to maintain health and weight, was 2,242 calories.

Langworthy, from collected statistical data, has compiled the following table:

RESULTS OF DIETARY STUDIES.

Occupation.	Food for one man each day. Protein grams.	Fuel Value calories.
United States:		
Man at very hard work (average 19 studies)...	177	6000
Farmers, mechanics, etc. (average 162 studies)..	100	3425
Business men, students, etc. (average 51 studies)	106	3285
Inmates of institutions, little or no muscular work (average 49 studies).....	86	2600
Very poor people, usually out of work (average 15 studies)	69	2100
Canada: Factory hands (average 13 studies).....	108	3480
England: Workingmen	89	2685
Scotland: Workingmen	108	3228
Ireland: Workingmen	98	3107
Germany: Workingmen	134	3061
Professional men	111	2511
France: Men at light work	110	2750
Japan: Laborers	118	4415
Professional and business men.....	87	2190
China: Laborers	91	3400
Egypt: Native laborers	112	2825
Congo: Native laborers	108	2812

From study of such data as these, estimates have been made of the amount of daily food that might be assumed to be most advantageous under different conditions of activity, and we are familiar with the dietary standards suggested by the following physiologists:

	Total calories in 24 hours.
Voit: Man at moderate work.....	3000
Rubner: Man at sedentary occupations.....	2445
Atwater: Man at hard muscular work.....	4150
Man at moderately active muscular work.....	3400
Man at sedentary or woman at moderately active work	2700
Man at no muscular exercise or woman at light work	2450
Chittenden: Business men	2800

That computation of the total calories from food consumed during a given period constitutes a reliable practical method for determining the daily available energy in any individual case is shown by the comparison of results in this method with the observations of direct calorimetry. For example, Doctor DuBois and Doctor Coleman, at the Russell Sage Institute of Pathology, at Bellevue Hospital, have shown that a patient in the respiration calorimeter by actual measurement generated 419.78 calories of heat during five hours. Calculations made from the value of the food ingested during the same period yielded 422.5 calories. This is a very striking agreement between theoretical and actual results.

The results of indirect calorimetry also have been shown to be strikingly in accord with those of direct calorimetry. In experiments on men resting or moving quietly within the calorimeter the following figures were obtained by Benedict, in 1889:

	I	II	III	IV
Estimated heat of combustion a day by measurements of oxygen consumed and carbon dioxide expired. Indirect calorimetry	2265	2272	2436	2356
Heat actually measured per diem in the calorimeter. Direct calorimetry.....	2283	2309	2394	2286

These observers have as a result of their experiments made the following estimates of energy expenditure by normal young men under various conditions of activity:

Man sleeping	65 calories an hour
Man sitting at rest	100 calories an hour
Man at light muscular exercise.....	170 calories an hour
Man at active muscular exercise.....	290 calories an hour
Man at severe muscular exercise.....	450 calories an hour
Man at very severe muscular exercise.....	600 calories an hour

An average day of sleep, rest, and active work is shown, therefore, to require fuel consumption about as follows:

8 hours sleep at 65 calories.. .....=	520 calories
2 hours light exercise at 170 calories=	340 calories
8 hours active exercise at 290 calories=	2320 calories
6 hours sitting at rest at 100 calories=	600 calories
Total food requirement for the day=	3780 calories

This is in substantial agreement with results of dietary studies of farmers, men who spend a large part of a long working day at severe muscular work:

	Calories in 24 hours.
Farmers in Connecticut	3410
Farmers in Vermont	3635
Farmers in New York	3785
Farmers in Mexico	3435
Farmers in Italy	3565
Farmers in Finland	3474
Average	3551

The most interesting of the recent experimental results published by Benedict and his associates (*Journal of Biological Chemistry*, March, 1915) are observations upon the "basal metabolism" of men and women. By "basal metabolism" is meant "the minimum heat production that is consistent with normal cell life in an individual at complete muscular rest, without food, and surrounded by a temperature of 30° C. or more."

In order to determine as closely as possible this basal metabolism, observations were made upon eighty-nine normal men and sixty-eight normal women, lying at absolute muscular rest in bed, and in the "postabsorptive" period, i. e., twelve hours after the last meal. Thus were eliminated all energy expenditures due to the ingestion of food, to muscular efforts, and to changes in external temperature, as the temperature of the chamber was kept constant. The conditions of these experiments were such as to give a more complete and accurate picture of the basal metabolism than any heretofore published.

AVERAGE VALUES FOR BASAL METABOLISM OF NORMAL MEN AND WOMEN.

	Age.	Weight kg.	Total Calories in 24 hours.	Calories to kg.	Calories to sq. meter body surface.
89 men	26	64.3	1638	25.5	832
68 women ...	27	54.5	1355	24.9	772

The basal metabolism is here shown to be very close to one calorie to the kgm. of body weight in one hour.

These results confirm the earlier figures of Magnus-Levy calculated by indirect calorimetry, which showed the "minimum metabolism of a man of average size, kept absolutely motionless and fasting" to be 1,625 calories a day.

It is perfectly clear, then, that the average adult human being requires for maintenance of body weight only, that is, for the performance of the vital internal work, maintenance of normal body temperature, and repair of the working cells, a minimum fuel supply of approximately 1,650 calories each day.

It has been shown, further, that if food is taken, the heat production will increase about ten per cent. over the basal metabolism. If the subject sits up in a chair, another increase of eight per cent. above the basal metabolism occurs; and if movements about the room are made, a twenty-nine per cent. increase follows. Thus a basal metabolism of 1,680 calories will be raised, as indicated above, to 2,168 calories. If a walk of two hours occurs during the day, the energy expended rises to 2,488 calories, a figure close to the statistical standards given earlier.

Scientific experiments have thus shown that about 2,500 calories a day represent the amount of fuel necessary and desirable for normal moderate activity. With every increase in the work done, more fuel is burned, more energy is discharged, more heat produced, more carbon dioxide and other waste products are excreted, and a corresponding amount of food is needed to supply the demands of this activity. Paul reminded the Thessalonians that "if any would not work neither should he eat." He might well have gone further, completing the circle of cause and effect, and added—if any will not eat neither shall he be able to work. Work means consumption of fuel, and efficient work means adequate fuel, a number of calories in the food equivalent to the energy expended in the work which must b done.

The idea at once suggests itself, however, that men and women of different size and weight must differ from one another in food requirement. The greater or less extent of body service in proportion to the weight is also of significance, as from the proportionately larger surface of the smaller mass there will be a proportionately greater radiation of heat, which must be made good by the burning of extra fuel. It is frequently useful, therefore, to consider the food or fuel requirement in terms of calories per kgm. of body weight, or calories to the square meter of body surface, and these data are noted in Benedict's figures given above.

Van Noorden suggests as the requirement for normal young adults:

At complete rest	30-35 calories per kgm. each day
With light exercise	35-40 calories per kgm. each day
With moderate exercise	40-45 calories per kgm. each day
With hard muscular work	45-60 calories per kgm. each day

Thus for the average individual of forty years of age, and of seventy kgm. weight (154 pounds), with moderate exercise, at thirty-six calories per kgm. each day, the requirement would be 2,520 calories, the amount which we have previously noted as desirable for these conditions.

Benedict's studies have shown, however, that with average adults no direct and simple relation can be traced between the rate of metabolism and the weight, height, and extent of body surface of the subject of experimentation. With differences in the taking of food, amount of muscular exercise, temperature of surrounding air, and age, eliminated, he believes that the basal energy exchange is proportional to the "mass of protoplasmic tissue" in the body, and to differences in "stimulus to cellular activity"—two factors difficult or impossible of measurement. Heredity, with its undoubted relation to the adequacy of the internal secretions and the "stimulus to cellular activity," must play some significant part in influencing the normal oxidative processes. But unless the subject differs very widely in height, weight, and extent of body surface, from the average figures for persons of his or her age, we are justified, for practical dietetic purposes, in assuming an average energy requirement proportionate to the activity.

Age, however, does play a significant part in determining the food needs. In the young, growing child there is need, first of all, for an abundance of tissue building foods, as cell construction is especially active; and there is need for a proportionately more abundant fuel supply than in the adult to support the more rapid rate of metabolism, to keep pace with the almost unceasing muscular activity, and to make good the greater radiation of heat from the proportionately larger body surface. The following table is useful (Sherman: *Chemistry of Food and Nutrition*, p. 172):

REQUIREMENT OF CHILDREN OF NORMAL SIZE, DEVELOPMENT, AND ACTIVITY.

	Total Calories.	Calories to kgm. of body weight.
Children under 1 year		100
Children of 1-2 years	900-1200	100-90
Children of 2-5 years	1200-1500	90-80
Children of 6-9 years	1400-2000	80-70
Children of 10-13 years	1800-2200	70-60
Girls of 14-17 years	2200-2600	60-45
Boys of 14-17 years	2500-3000	60-45

In aged persons, on the other hand, there is a much less active metabolism, very little cell construction, and less active muscular work. It is suggested that the caloric requirement of children may be considered to be one third greater than that of young adults, while that of elderly persons is one quarter less.

(*To be continued.*)

Treatment of Obesity by a Rational Diet.—Edward E. Cornwall (*Boston Medical and Surgical Journal*, October 26) gives practical suggestions for regulating the diet in obesity. Regulation of the diet should be qualitative as well as quantitative. Insist on scales and measures being used to secure accuracy in carrying out dietetic prescriptions. Do not rely for protein chiefly on animal tissues and eggs, but secure it from milk and its products. If no other morbid condition is present a small amount of animal tissue and eggs may be included in the diet, but this should be excluded when there is obvious insufficiency of nitrogenous metabolism, or there is disease of the alimentary canal. Include plenty of fresh fruits and vegetables, but select carefully so as to include only those which are comparatively free from objectionable qualities, such as indigestibility, possession of purin or oxalic acid content, and offensiveness to the patient's idiosyncrasies. Allow water in ordinary quantities. Begin the treatment by restricting the fuel ration so as to supply about 1,000 calories less than the minimum health ration for the particular pa-

tient. Do not reduce the quantity of protein much below the minimum health ration; let the loss fall chiefly on the fat and carbohydrate. Do not, as a rule, try to reduce the weight by more than two pounds a week; such a moderate reduction is not often attended by unpleasant consequences. Bear in mind the exceptions which exist in regard to reducing weight; be cautious in reducing the weight of those afflicted with serious disease; relax the rigidity of the diet, or discontinue all attempts at reduction, if in the course of treatment symptoms of distress or weakness appear; do not, as a rule, attempt to reduce the weight of those entering on old age who have been obese for a considerable time. In most cases allow occasional periods of rest from the rigid diet, and, while giving the minimum health rations, take note if the weight increases in consequence.

Medical Treatment of Gastric and Duodenal Ulcers.—Seale Harris (*Southern Medical Journal*, November, 1916) simplifies and modifies the Lenhartz diet so that it can be carried out with greater accuracy by the average nurse or attendant than the one originally devised. The Lenhartz diet consists principally of eggs, milk, cane sugar, scraped beef, raw ham, rice, and zwieback, which are prepared separately and given in definite quantities, expressed in grams, every hour from 7 a. m. till 9 p. m. for ten days. Harris has the nurse prepare enough of a mixture in the proportion of one egg and one and a half ounce of cream to four ounces of milk, and gives it every hour from 7 a. m. to 7 p. m., in gradually increasing quantities, beginning with half an ounce the first day and increasing half an ounce each day. In six days the quantity at each feeding is three ounces, and this quantity is maintained for four days. From the seventh to the tenth day a soft cooked egg and two tablespoonfuls of strained oatmeal may be given with the feeding at 7 a. m. and 7 p. m., and at 1 p. m. two tablespoonfuls of scraped beef lightly broiled and two tablespoonfuls of thoroughly cooked rice with butter. After ten days until the fifteenth day, three ounces of the egg, milk, and cream mixture are given at 9 and 11 a. m., and 3 and 5 p. m.; two ounces of strained oatmeal with cream and sugar, and one or two thin slices of dry toast and two soft eggs for breakfast at 7 a. m. and supper at 7. p. m.; and chopped or minced chicken or scraped beef, dry toast, rice, and ice cream or gelatin at 1 p. m. Butter is allowed after ten days. Beginning with the fifteenth day, for two months the patient is to have small meals, three times a day, with an egg and a goblet of milk between meals and at bedtime. The egg, milk and cream mixture should be kept in a covered dish with ice packed around it. The amount for each feeding should be given slowly and with a spoon, with the same exactness and regularity as if it were medicine. The scraped beef should be made into a patty and lightly broiled with a little butter and salt. The rice and oatmeal should be cooked for several hours. The dry toast should be in slices about four by four and a half inches in size. The crust should be removed and the patient instructed to chew it until it becomes liquid.

He says that it is surprising how the pain and discomfort is relieved by giving half an ounce of the egg, cream, and milk mixture every hour. The patients gain in weight, the anemia subsides, and the strength of the patient is built up rapidly on the diet prescribed, which may be begun within forty-eight hours of a hemorrhage, and in three or four days after a gastroenterostomy. In a few instances the mixture has disagreed, and then the quantity of food is reduced for a few days. Approximately the total number of calories are for the first day 300, for the second 600, for the third 900, for the fourth 1,200, for the fifth 1,500, for the sixth 1,800, for the seventh to the tenth 2,100, for the eleventh to the fourteenth 2,800, from the fifteenth to the twenty-first 3,000, and from the third to the sixth week 3,500. For a year after that the diet should be such as is indicated in hyperchlorhydria. It should be highly nutritious, from 3,000 to 3,500 calories, because the building up process in ulcer is as important as in tuberculosis. Highly seasoned foods, pepper, spices, condiments, and pickles should be avoided, as should also hot bread and fried foods. most sweets, tough meats, corn, and fruits and vegetables that contain hard seed or have tough skins. Coffee, tea, and all other caffeine beverages, wine, beer, and other alcoholic drinks as well as tobacco, should be tabooed.

Malt Soup Extract in Infant Feeding.—B. Raymond Hoobler (*Journal A. M. A.*, Nov. 11, 1916) likes Liebing's original plan, which is to employ malt soup for the nutrition of normal infants, especially those which are stationary in weight and in which there is a tendency to constipation. This seems to Hoobler to be the great field for the use of this food, but for this purpose the formula of Keller—now generally employed—requires modification. This is true, first, because boiled milk should not be given for a long time to infants with constipation; second, because raw or inadequately cooked starch should not be given to infants; third, because the proportions are not correct for all cases; and, fourth, because the amounts specified are too arbitrary. Hoobler, therefore, modifies the preparation of malt soup as follows: Using the desired quantity of the particular cereal indicated, one quart of cereal water is to be made by cooking for not less than one hour in a double boiler. When cooked and still hot, add two level tablespoonfuls of malt soup extract, stir until dissolved, and strain. Then measure out the amount and kind of milk desired, add enough of the mixture of cereal and malt to complete the formula, then add the requisite sugar. Using this plan a formula is to be tried for two or three days, and is then continued, increasing the proportion of malt soup and cereal mixture if there is no change in the stools or the weight. If the formula is near the point of carbohydrate tolerance, each increase in malt soup extract should be met by a reduction in the added sugar. The choice of the cereal should depend upon the effect desired—thus oatmeal is laxative, while wheat flour is only mildly so, and barley and rye are intermediate. The response of the infant, however, will vary in great measure with the particular intestinal flora, and the choice of the cereal must be largely experimental in each case.

THE GENERAL PRACTITIONER'S DUTY TO HIS COUNTRY.

Although the subject has been argued at great length in the lay press, and has given birth to political planks and moving picture shows, so far it has seemed to touch the medical profession remotely, if at all. Some of us believe that back of the agitation are the munition makers; many of us think that, prepared or unprepared, Uncle Sam could whip all the nations in the world, separately or together, but we all know that, should the time come for action, we would do our part. The chief disagreement concerns the time when we should begin to prepare; when we have time to think, it is to rest comfortably in the assurance that the routine of our daily work is sufficient preparation.

Any physician is invited to have this optimistic view quickly dispelled by an interview with a military surgeon. Only army surgeons realize how greatly military medicine differs from civil practice, and what an enormous amount of experience is required before the family physician can be transformed into the military surgeon. In the army efficiency is based on discipline; the civil practitioner, accustomed as he is to a position of importance in his community, is slow to recognize this. It galls his pride to find that he is a mere unit in a vast machine; it is irksome for a college professor to be subordinate to his former pupils, and to adapt himself gracefully to changed conditions such as these, requires practice.

The whole matter of preparedness for the civilian physician is discussed by Colonel La Garde in the *Military Surgeon* for September. He calls attention to the numerous accounts in military history of expeditionary forces coming to grief through disease rather than a hostile force, and contrasts these accounts with the good health record of American troops in the tropics in recent years. This is entirely due, he says, to the highly specialized efforts of the medical corps.

La Garde estimated the problem we should have to face in the event of war somewhat as follows: The first call would probably be for a million men; for these would be required about 10,000 medical officers. The regular army could offer 443 surgeons, which would mean that approximately 9,500 must come from the civilian population; of this number 3,000 would be required to take care of the sick and wounded, i. e., perform duties very similar to their daily routine in civil life. The remaining 6,500 would be needed to look after sanitation, hygiene, and administrative matters.

Is the average civil practitioner qualified, even in an elementary way, for such duties? It would seem not. For the army in selecting its medical officers raises its requirements very high; it takes only graduates of first class schools who have had at least one year's hospital experience, and who must still pass a rigid mental and physical examination. It gives them nine months' intensive training in the Army Medical School, the curriculum including military surgery, medical department administration, ophthalmology, tropical medicine, military hygiene, sanitary chemistry, bacteriology, pathology, laboratory diagnosis, sanitary tactics, operative surgery, röntgenology, and psychiatry. Even then they are required to spend a year in the field before they are considered fully fledged. The average practitioner cannot find time for such a course as this, but La Garde suggests three ways in which he can obtain preparation: The National Guard and the Medical Reserve Corps for the younger men, and the Red Cross for the older men.

Camps of instruction for the former two have been ordered at Tobyhanna, Pa., Anniston, Ala., Sparta, Wis., Fort Riley, Kans., and Monterey, Cal. Here courses will be given in physical exercise, sabre, litter, and tent drill, administration of regimental hospital, field hospital and ambulance company, stable management, recruiting, camp sanita-

tion, public health matters, transportation of the sick and wounded, hygiene of troops, and many other matters pertinent to military medicine, not to mention the intangible but indispensable something which we call, for want of an equivalent, *esprit de corps;* moreover, there is acquired a respect for discipline, together with assurance and self confidence.

In the Spanish-American war there were six civilian surgeons to every military one, while in the Civil War the ratio was sixty-six to one. Should war come now, the ratio, at first, would probably be about twenty to one. La Garde urges all young medical men to enter the Medical Reserve Corps, and the older ones to join the Red Cross, so that the twenty may be valuable aids to the one. When our profession realizes that it can aid much in mitigating the horrors of war as well as perform a patriotic service it will not be slow to do its part.

THE ENDEMIC INDEX IN MALARIA.

The prevalence of malaria in the southern States is, together with hookworm infection, the greatest factor in delaying the progress of a great mass of people. The amount of actual illness and disability is likewise large. While present in the northern States, the disease does not constitute the problem that it does in the south; yet an intensive examination of northern communities, on somewhat the scale carried on in the south would undoubtedly show a greater prevalence than is now realized. A great many of the vague conditions now remaining undiagnosed could be brought within the fold of this disease. Wherever there are breeding places for anopheles, whether in the north or in the south, there will malaria flourish. Because of the greater area for the presence of stagnant water, the country is the place of selection for malaria. Clearing out brush and ditches eradicated the infection by depriving anopheles of breeding places. In the cities the same conditions can be simulated by street pools, defective house drains, uncovered water tanks, and the like. In the eradication of yellow fever from urban communities, these were the very conditions which furnished breeding places for stegomyia, and demanded attention.

In some of the southern States as many as seventy-five per cent. of a working community would often be incapacitated, although the absolute average of malarial attack did not perhaps exceed five per cent. each year. Because of the early seasonal increase of malaria, the carrier population must be very large. As in other conditions in which the carrier is a factor, the carrier is himself not actively suffering with the disease, although he is the factor in keeping it alive in his community. For this reason it was desirable to determine what proportion of a community showed infection and acted as carriers. Von Ezdorf (*Public Health Reports, 331*) found that the endemic index of malaria, that is the proportion of people having malarial infection without manifesting the disease, was about 13.5 per cent. The malarial rate, on the other hand, refers to the number of people having malarial fever at one particular time, which is about five per cent. Both the individuals in the index and in the rate can cause new infections. Of those harboring the plasmodium, however, only about one in four has the sexual form (gametocyte) necessary for infecting a malaria bearing anopheles, and is, therefore, a potential malarial carrier at all times.

The methods used for determining the endemic rate were the spleen method, the parasite method, and the combined method. The spleen, as indicator of the presence of malarial infection, is inaccurate because it is usually palpable in young children and in other conditions. The method does serve as a broad guide where a great number of people are to be included in the survey. The blood or parasite method is the method of choice. Thick blood smears are better, because there is a larger yield in a shorter examination time. It is estimated that about twenty-five per cent. of results with thick smears are not confirmed with thin smears of the same blood. The percentage of infections found by the blood smear is in inverse proportion to that found by the spleen method; in other words, the endemic rate by the blood smear method is in inverse proportion to the spleen rate. In malarial enlargements the plasmodia are hidden in the spleen and are not present in the blood stream. This occurs in the chronic malarial infections and cachexias which are so hard to treat.

For a real average rate all ages must be examined, but the best representative rate will be found in children between the ages of ten and fifteen years; at these ages the high mortality of children will have expended itself and cannot so much affect the statistical considerations. The percentage of cases, however, is highest between the ages of one year and three years; lowest between ten and fifteen years of age. The tertian type of malarial organism is found twice as frequently as the estivoautumnal.

With the endemic rate high, and kept high by conditions favoring mosquito breeding, the malarial rate will continue to be high and hard to reduce. The malarial rate is always in proportion to the endemic index—the carrier index that furnishes the infection for the malaria breeding anopheles. In malaria we have a condition that is very prevalent, and yet so preventible that there is no excuse for its existence in civilized communities.

THE DIET OF BRITISH MUNITION WORKERS.

The European war has already brought into a new light some interesting facts with regard to diet. It has been stated that the Germans, who were accustomed to a generous way of living, and who never stinted themselves in the matter of meat, on the restricted diet rendered necessary by the exigencies of war are now in better health.

The munition workers of Great Britain are, for obvious reasons, being put on a restricted diet. Dr. Leonard Hill, on behalf of the Health of Munition Workers' Commission, has published recently a report on the cost and nutritive value of the food supplied to this large class of the community, as an appendix to a memorandum dealing with questions in relation to the war. As to diet, he proceeds on the principle that the amount of food taken should be regulated solely by the loss of energy it is required to replace, and points out that fortunately the chief food stuffs really provide all the nourishment that is requisite to health, better, indeed, than the more highly flavored and expensive foods which stimulate the appetite artificially. The composition of the canteen meals for munition workers is based on the premise that a man engaged in light munitions work requires an energy produced by 3,500 calories of food. This was made the subject of careful analysis.

The average canteen dinner was found to be a good one, containing an energy value of about 1,000 calories, well distributed among the amounts of protein, fat, and carbohydrate. The cost of such a meal varied from ten to eighteen cents. An investigation was also made of the meals provided at home, and it was found that in a general way the meals of the men workers were adequate, but that in those of girls, there was a wide variation from 300 up to 1,000 calories. The meals of the latter before starting work often consisted of white bread and boiled tea. The memorandum finishes with a table of simple daily meals designed to secure a well balanced dietary for munition workers. Each of the five daily diets given contains about 3,000 calories at a cost of from forty-eight to fifty-two cents on the basis of prices ruling in April, 1916. It may be noted that the staple diet of the British munition workers consists of bread, oleomargarine, oatmeal, milk, herrings, cheese, beans, cabbages, oranges, and the cheaper kinds of meats.

The lesson to be learned from a study of the restricted diet prevailing in the belligerent countries of Europe, is that, provided there is a sufficiency of food, and that the various articles of diet are well balanced, the need for meals consisting principally of meat and potatoes is greatly overestimated. In fact, it might be affirmed that in prosperous times many persons not only eat too much, but meat forms a much too great proportion of their diet.

HEALTH TRAINING VERSUS PHYSICAL TRAINING.

One of our universities which has long had a department of physical training has recently organized a department of health. The change, even if it is rather one of words than of works, is significant.

Physical training, no matter what it has come to include, originated in, and consists chiefly of muscular training or exercise. This modern movement began in Germany and Sweden somewhat over a century ago, as a reaction against rapidly increasing sedentariness with the bodily results which this habit, and its companion, excessive feeding, bring to pass. The exercise movement, with all the fine theories and practices which sprang out of it, has spread until every educational institution in the land gives its daily or weekly dose (too often homeopathic) of gymnastics to all its pupils, and, in the same name, encourages practices that go to a strenuous extreme under the title of athletics.

While the department of physical training has often tried to do more than encourage exercise—and it has found even this no easy matter—it has come to stand, in the average mind, for nothing else, and though it has often tried to stem the tide of athletics for the few and bleachers for the many, the department has ever been confounded with athletics. That this confusion should arise is not to be wondered at, since most of the colleges have chosen for the head of this department either an acrobat or an athlete, who knew and cared no more about the principles of health than a babe unborn.

Muscular exercise is but one of the many essentials for health preservation, and as the formal exercise of the gymnasium is usually given at such long intervals and in such small amounts as to be practically worthless, and the interscholastic athletics are too condensed in time and in severity, the student who is excused from gymnastics, or who sits on the bleachers and waves his hands and shouts for the team, is about as well off as the athletic student so far as preserving his health is concerned. While it is difficult to impress on youth the importance of health, or to "train" him in the ways of health maintenance, the time is ripe for such an effort, and it is far better to have a department which stands, in name at least, for health, rather than for muscular exercise. The head of that department, even if he is the same person, takes on new dignity.

Our schools are slow in their efforts to teach the theoretical subjects which bear on health. Hours

are given to Latin and ancient history where seconds are devoted to hygiene and sanitation. There are few colleges for men in which physiology and hygiene are required subjects, and fewer which present these subjects in an adequate manner. The colleges for women do better, and at least one of these gives an elective course in physiology that surpasses that of many medical schools. The general principles of public health should be carried from college into practical life, in the midst of which most graduates are immediately plunged.

The health department of a college has indeed plenty to do beside the important matter of looking after the health conditions under which its pupils labor. It is to be hoped that the management of such institutions will be so intelligent as to give this new department the opportunity to do what its hands find to do.

POLIOMYELITIS AND HIP DISEASE.

There are many, remarks in part the *Medical Press* for November 8, 1916, who can call to mind instances in which they have examined cases in which a tentative opinion has been given in favor of a tuberculous lesion of the hip, which on examination and inquiry turned out to be nothing else than the resulting deformity from an undiscovered, and perhaps almost unnoticed attack of anterior poliomyelitis. The number of articles that have been elicited by the New York epidemic all combine in describing an onset in this disease that may be as marked as possible, or yet be so slight as to escape attention were it not for the watchfulness and care on the part of the health authorities, and therefore the possibility of even a mother missing the slight symptoms of an evanescent attack is very large. In almost all cases, however, a careful cross questioning will bring forth the information that at some period, which the parents had not before thought of, the child either was off color, vomited, or manifested some of the protean symptoms with which the disease may manifest itself. The gradual shortening of a leg, with the consequent disinclination to use it that the postparalytic contraction causes, may then be traced with a fair assumption of being correct. The fact that specialists of all kinds have found something to remark upon as touching their divers realms in the points about poliomyelitis goes far to prove that many obscure little troubles that have come before the medical man in general practice have possibly their origin in a remote and happily mild visitation of a disease full of alarming possibilities.

News Items

New York Physicians' Association.—At a regular meeting of this association, held on Thursday, November 23d. Dr. Alfred Stengel, of the University of Pennsylvania, delivered an address on Practical Differentiation Between the Various Types of Chronic Nephritis.

Leprosy in Milwaukee.—Senior Surgeon Banks, of the United States Public Health Service, reported a case of leprosy in Milwaukee, Wis., on November 2d. The patient is a Greek, aged twenty-two years, who was born in Turkey, and came to this country in 1910. Symptoms of the disease were noticed about a year ago.

Meetings of Medical Societies to Be Held in Philadelphia during the Coming Week.—Monday, November 27th, Section in General Medicine of the College of Physicians, North Branch of the County Medical Society; Tuesday, November 28th, West Philadelphia Medical Society; Tuesday, November 28th, West Philadelphia Medical Association, Academy of Stomatology; Friday, December 1st, Kensington Branch of the County Medical Society.

Tuberculosis Prevention in Dallas, Texas.—A branch of the National Association for the Study and Prevention of Tuberculosis was organized in Dallas, Texas, on Tuesday, November 14th. According to health department estimates there are at present 1,500 cases of the disease in Dallas, but complete statistics are not available. It is believed, however, that in regard to tuberculosis the city ranks above the general average of cities of 100,000 population, and for that reason it has been decided to take active steps toward preventing the spread of the disease.

Physicians Wanted in the Indian and Panama Canal Services.—The United States Civil Service Commission announces that an examination open to men only will be held on December 13th, at various places throughout the country, to secure a list of eligible persons from which to fill the position of physician in the Indian and Panama Canal Services. The entrance salaries in the Indian Service range from $1,000 to $1,200 a year, and in the Panama Canal Service the salary is $1,800. For full information regarding this examination, address the United States Civil Service Commission, Washington.

Personal.—Dr. H. Brooker Mills has been appointed visiting physician to the Philadelphia Hospital for Contagious Diseases.

Dr. Elwood R. Kirby has been appointed chief surgeon of the genitourinary department of the Philadelphia General Hospital.

Dr. J. L. Greene, formerly superintendent of the State Hospital for Nervous Diseases in Little Rock, Arkansas, and Dr. M. F. Lautman, formerly medical director of the Levi Memorial Hospital, Hot Springs, Arkansas, announce their association for the practice of medicine with offices in the Dugan-Stuart Building, Hot Springs.

Philadelphia County Medical Society Aid Association.—At the annual meeting of this association, held on Monday, November 13th, the following officers were elected: Dr. J. R. Shellenberger, president; Dr. E. E. Montgomery, vice-president; Dr. John B. Turner, treasurer; Dr. Lewis H. Adler, Jr., secretary. Dr. James M. Anders, Dr. J. Solis-Cohen, and Dr. William H. Welch were reelected directors to serve for four years. Dr. S. D. Risley was elected chairman of the board of directors, and Dr. Lewis H. Adler, Jr., secretary. Dr. S. W. Morton was elected chairman of the Committee on Benevolence, and Dr. J. Solis-Cohen and Dr. I. P. Strittmatter were elected members of this committee.

National Board of Medical Examiners.—This board, which was founded in 1915 by the late Dr. William L. Rodman, of Philadelphia, held its first examination in Washington, D. C., October 16th to 21st. There were thirty-two applicants from seventeen States, representing twenty-four medical schools, and of these sixteen were accepted as having the necessary preliminary and medical qualifications. Ten of these candidates took the examination, and the following passed: Dr. Harry Sidney Newcomer, Johns Hopkins University; Dr. William White Southard, Johns Hopkins University; Dr. Orlow Chapin Snyder, University of Michigan; Dr. Thomas Arthur Johnson, Rush Medical College; Dr. Hjorleifur T. Kristjanson, Rush Medical College. The second examination will be in Washington in June, 1917. Further information may be had by applying to the secretary of the board, Dr. J. S. Rodman, 2106 Walnut Street, Philadelphia.

Testimonial Dinner to Eugene W. Scheffer, Secretary to the Board of Health.—A testimonial dinner to the retiring secretary of the Department of Health of the City of New York, Mr. Eugene W. Scheffer, was given at the Yale Club on Tuesday evening, November 14th, about 150 guests participating. Addresses were made by Dr. S. S. Goldwater and Dr. Thomas Darlington, former commissioners of health, by Rhinelander Waldo, Esq., and Thomas F. McAvoy, Esq., former commissioners of police, George Foulk, Esq., Professor William H. Park, Dr. Robert J. Wilson, and Assistant Corporation Counsel William J. Millard. Others present included Magistrate Nathaniel Marsh, Deputy Health Commissioner John S. Billings, and all the directors of bureaus in the Department of Health. Dr. William H. Guilfoy, registrar of records, acted as toastmaster. At the conclusion of the dinner Mr. Scheffer was presented with a handsome gold watch and chain. Mr. Scheffer entered the Department of Health as assistant chief clerk in 1895 and became secretary in 1902, serving under Health Commissioners Lederle, Darlington, Goldwater, and Emerson. He retires on pension at the close of the present year.

Gifts and Bequests to Hospitals.—Many charitable bequests are provided for in the will of Samuel Hirsh, who died in New York on October 8th, among them being the following: United Hebrew Charities, $100,000 for the establishment of memorial funds to be called the David and Lottie Hirsh Fund; $1,000 to each of the following hospitals: Jewish Maternity Hospital, Beth Israel Hospital, Lebanon Hospital, Sanatorium for Jewish Children at Rockaway, Hospital for Deformities and Joint Diseases, Mt. Sinai Hospital, and Montefiore Home.

Included in the will of the late T. Morris Wright are the following bequests: $10,000 to the Philadelphia Home for Incurables; $5,000 each to the Pennsylvania, Hahnemann, Jewish, Jefferson, and German Hospitals, to the Children's Aid Society, and the Society to Protect Children from Cruelty. The Philadelphia Home for Incurables becomes a residuary legatee.

By the will of Mrs. Caroline Augusta Wilson, who died in New York on April 19th last, the Presbyterian Hospital will receive $25,000.

The Memorial Hospital, at Morristown, N. J., will receive $5,000, under the terms of the will of the late Joseph W. Ogden.

Resolutions on Poliomyelitis.—At a meeting of the New York Neurological Society, held on Tuesday evening, November 14th, Dr. Walter Timme presented the following resolutions which were adopted unanimously by the society:

WHEREAS, Anterior poliomyelitis and its concomitant polioencephalitis are intrinsically neurological diseases, and

WHEREAS, Anterior poliomyelitis and polioencephalitis have been managed in all stages in the recent epidemic practically without the supervision and control of neurologists in the institutions of Greater New York, and

WHEREAS, In order to avoid faulty diagnoses, inadequate treatment, and poor methods of gathering important statistics, resulting not only in detriment to the present patients, but also in a final loss to scientific medicine of valuable data of great service in future epidemics; be it

Resolved, That it is the sense of the New York Neurological Society that anterior poliomyelitis and polioencephalitis being neurological diseases, the sufferers from such diseases ought at an early period to come under the care or supervision of neurologists, with the cooperation of orthopedists and other specialists as the cases may require:

And, in consideration of the unprecedented number of cases in the recent epidemic, in all public institutions and clinics where these diseases are treated, there should be a standardization of equipment and method. And be it further

Resolved, That the New York Neurological Society petition the Committee on Public Health of the New York Academy of Medicine that it consider the advisability of appointing at once a Commission on poliomyelitis which shall take into consideration the ways and means best calculated to meet and combat a future epidemic similar to the one we have just experienced and make definite recommendations for same. This Commission shall consist of four subcommittees as follows:

First a Committee on communicability and quarantine composed of bacteriologists and epidemiologists.

Second, a committee on the criteria of diagnosis and clinical management to consist of neurologists, pediatrists, and orthopedists.

Third, a committee on pathology and serology to consist of pathologists who shall devise the best means of caring for such pathological material as is obtained as a result of the epidemic.

Fourth, a committee on treatment and immunization to consist of neurologists, orthopedists, pediatrists and bacteriologists. This committee shall consider the therapeutic means best adapted to the acute stage and also to the after-treatment.

Pathologists Wanted in the City Service.—The Municipal Civil Service Commission of New York is endeavoring to secure a number of competent physicians for the position of pathologist. Unusual opportunities are offered a man who is desirous of securing wide experience in the performance of autopsies, in microscopic diagnosis, and in chemical pathology. The competition is open to citizens throughout the United States over twenty-one years of age holding a degree of M. D. The examination will consist of an experience paper, a technical, and a practical test.

Candidates all over the country will recognize the fact that the salary of $1,500 per annum is made more attractive by the opportunities for unusual practical experience afforded a pathologist in New York city. The present vacancy is in Kings County Hospital, an institution with an average census of 1,500 patients. Applications will be received from November 20th to December 5, 1916. For further particulars see the *City Record*, published daily, or apply to the Municipal Civil Service Commission, Room 1400, Municipal Building, New York, N. Y.

Medical Society of the County of New York.—The annual meeting of this society will be held in Hosack Hall, New York Academy of Medicine, Monday evening, November 27th, at 8:15 o'clock, under the presidency of Dr. Frederick E. Sondern. At the scientific session the following papers will be read: Technic of Painless Radical Cure of Hernia under Local Anesthesia, illustrated by motion pictures, by Dr. John A. Bodine; Approach and Entrance to the Kidney for the Removal of Calculi, illustrated by motion pictures, by Dr. Charles H. Chetwood; Motion Photographs as Adjuvants to the Teaching of Surgery, with notes on the development of the operation of bloodless amputation at the hip and at the shoulder joint, of the operation of ligature of the external carotid artery, the use of boiling water for the cure of otherwise inoperable vascular neoplasms, by Dr. John A. Wyeth; Operation for Repair of Rectocele, demonstrated by motion pictures, by Dr. Thomas H. Morgan. At the December meeting of the society, which will be held on Tuesday, the 26th, a report on the medical aspects of birth control will be presented by a special committee appointed by the society to investigate the subject.

Clinic Physicians Wanted by the Health Department.—The Municipal Civil Service Commission will shortly hold an examination for clinic physician, applications for which must be filed before December 1st, for the purpose of filling vacancies in the department of health. The duties of a clinic physician are to diagnose and treat patients applying at the tuberculosis clinics of the department of health and to examine, at the occupational clinic of the department, applicants for licenses as food handlers. Eight hours of service each week are required. Candidates must be at least twenty-one years of age and must present evidence of one year's service as an intern in a hospital or sanatorium or at least two years' experience in outpatient work or its equivalent. Candidates for this examination must also be licensed to practise medicine in the State of New York and must present their licenses for inspection at the time of filing applications.

The fact that the occupational clinic, situated at 49 Lafayette Street, New York, is the second one of its kind in the world should arouse the interest of all ambitious physicians who are residents of the State of New York to enter the contest, because of the unusual fields it offers for research and invaluable experience. Aside from the experience and education connected with the work, the clinic physician is fitting himself for a new phase of medical practice—that of industrial corporation service.

The compensation rates proposed by the Board of Estimate and Apportionment for this position are $300 to $600 for not less than six hours work each week, or $900 to $1,140 for not less than eighteen hours each week.

For further particulars apply to the Municipal Civil Service Commission, Room 1400, Municipal Building, New York city.

Modern Treatment and Preventive Medicine

A Compendium of Therapeutics and Prophylaxis, Original and Adapted

THE THERAPEUTICS OF A PHARMACOLOGIST.

By A. D. Bush, M. D.,

Professor of Pharmacology and Therapeutics, University of Southern California.

Forty-fifth Communication.

CATARRHAL GASTRITIS (*continued*).

Although important variations in the quantity of pepsin have not been demonstrated, it is well known that the hydrochloric acid content may show wide divergences from the normal, with corresponding influence on the digestive processes. When there is a deficiency in this mineral acid constituent of gastric juice the pyloric sphincter tends to remain contracted, with retention of food in the stomach. At the same time, the pepsin is relatively inactive through want of a suitable medium, and the food mass tends to ferment and decompose, resulting in irritating organic acids and abnormal gases. The logical treatment in such a case is the administration of the deficient acid.

A further important point in considering hypochlorhydria is the deterrent effect of this abnormal chyme on duodenal activities. The present teaching in physiology is that the acid chyme provokes the development of secretin in the duodenum, which is a hormone stimulant for the pancreas. In the absence of this initiating stimulus, the normal cycle of events is lost, and further aberrancies of alimentary activity develop in the bowels. All this may be alleviated and promptly cured by the timely administration of dilute hydrochloric acid.

An opposite factor in producing gastric disturbances, with unpleasant enteric sequences, is hyperchlorhydria. In this condition, the excessive acidity tends to undue relaxation of the pyloric sphincter, despite the added contrary stimulus from the duodenal side; this tends to a hastening of the highly acid chyme into the small intestine, which may result in an overpowering of the neutralizing action of the bile with serious disturbance in pancreatic digestion as a result, and a continuance of the disturbance further down the tract. In this condition, the administration of an alkali is the immediate need; this may be followed by a relative increase in the proteins of the diet; the secondary need is a search for the underlying metabolic factors at fault.

Just what may be the obscure factors producing variations in the acid content of the gastric juice does not appear. There seem to be indications that the oscillations of the H ions in gastric juice vary inversely with the relative alkalinity of the blood. There are also indications that diminished bile production is accompanied by heightened acidity of the gastric juice, but no immediate causal explanation is offered. Evidently we shall have to obtain a determination of these underlying factors before our therapeutic efforts advance much beyond the treatment of symptoms. The present rational method of attack is to discover whether there is excess or deficiency of hydrochloric acid in the gastric juice, and then to meet the definite indications by supplying promptly the particular chemical required, and to discover if possible what systemic dyscrasia may coexist.

When the temporary distress is too marked we may resort wisely to epigastric counterirritation for resolvent effect, and to codeine for depression of consciousness.

In the chronic type much relief may be had by an anteprandial dissolving of the viscid mucus by sipping hot water; removal of this mucus permits of a more ready attack of the food by the pepsin of the stomach.

Too much stress cannot be laid on the desirability of regulating the diet to the systemic needs of the individual, using more protein for the carnivorous type and more carbohydrate for the herbivorous type. Such articles as are difficult of digestion should be discarded altogether, or else partaken of at times only when digestive power is at an adequate maximum. Irritants and secretory depressants should be eliminated. The best prophylactic for gastric disorders is a diet of simple, wholesome food, spiced with variety, and seasoned with good cheer.

ENTERITIS.

Since most cases of catarrhal enteritis, as well as of gastroenteritis, are due to the presence of irritating substances in the alimentary canal, the leading indication, often unobserved, is to clear the tract of the offending material as expeditiously as possible; and for adults no cathartic is more efficient than castor oil. To this oil, to prevent griping as well as to relieve colic, may be added a few drops of laudanum or of paregoric—but not enough to depress peristalsis. Castor oil is best taken at the soda fountain, where it may be combined with a syrup, and then intimately mixed by means of the fine hard stream of vichy. For children, a preparation as a substitute for the oil is a combination of aromatic tincture of rhubarb with senna, both of which act by increasing secretions and the peristalsis of the small intestine. Following this purgation, the alimentary tract should be given a period of rest for a day or more; it will be well, also, if the entire body is kept at rest in bed. In fact, removal of the irritating material, followed by a period of rest, is practically all that is necessary in the treatment of a majority of these cases.

There are some cases of enteritis where the fault lies in a disturbance of secretion. Hypacidity of the gastric juice results in a failure to incite the secretion hormones which stimulate pancreatic activity; as a consequence, the duodenal digestive action is inadequate and imperfect. Abnormal split products act as irritants to the intestinal epithelium, and there ensues the defensive congestion termed enteritis. Or hyperacidity swamps the neutralizing power of the duodenal juices and pancreatic digestion fails because of an unfavorable medium, with the result that the products of abnormal food de-

composition act as irritating substances. Or interference with the bile flow lowers the neutralizing capacity of the duodenal juice with a similar inhibition of pancreatic activity. In these circumstances again the first indication is to clear the alimentary canal of decomposing material as speedily as possible; the second indication is to give the inflamed mucosa time and opportunity to regain its normal condition; the third equally important indication is to correct the disturbed function. This duty, though difficult and requiring much scientific skill and patience, should not be neglected.

A few cases of disordered function are apparently psychic in origin, the emotional reactions inhibiting some secretions and overstimulating others, in either case resulting in perverted digestion products and alimentary disturbances of far reaching character. These cases are peculiar to themselves and require careful study; perhaps the rest cure is needed in some cases, wholesome mental suggestion in others, and strict alimentary regimen in all. Probably some of these cases would be benefited by one to three days' starvation treatment.

A word of caution should be given concerning the use of drugs in intestinal troubles. Acute pain may justly be alleviated, but discomfort only does not warrant an opiate. Intestinal and bodily rest are ordinarily adequate for recovery, unless there is an accompanying infection. Intestinal antiseptics and disinfectants are useless. Demulcents are sometimes beneficial because of the protection they afford. Internal astringents are rarely indicated. About the only drug that seems of general benefit is strychnine; the heightened spinal reflexes produced by this drug favor rapidity of metabolism.

Tartar Emetic in Protozoal Diseases.—Aldo Castellani (*Brit. Med. Jour.*, October 21, 1916) states that tartar emetic is most efficacious in yaws, but its action is not very rapid and prolonged treatment is necessary. An easy method of administration is therefore requisite and the oral route has been adopted by Castellani, who uses the following formula:

℞ Antimonii et potassii tartratis, ...0.065;
Sodii salicylatis, ...0.6;
Sodii bicarbonatis, ...1.0;
Potassii iodidi, ...4.0;
Glycerini, ...8.0;
Aquæ, ...q. s. ad 30.0

The foregoing is a single dose which should be given diluted with about four times as much water and administered three times daily. In children of eight to fourteen years half the dose, and in younger children one third the dose is given. Tartar emetic and potassium iodide are the active drugs; the sodium salicylate seems to hasten the disappearance of the yellow crusts; the sodium bicarbonate decreases the emetic action and to a certain degree prevents iodism; and the glycerin serves to maintain a clear solution. Tartar emetic is also very effective in kala azar and may be given either intravenously, intramuscularly or orally. For intravenous injection a sterile one per cent. solution in normal saline may be used in doses of two to ten mils daily for ten days and later every other day or twice weekly. The following is also a most useful formula for intravenous use in doses of half to two mils, diluted at the time of injection to five mils with normal saline:

Tartar emetic, ...4.0;
Phenol (two per cent.), ...100.0.

For intramuscular injection two formulas have proved satisfactory; the first is slightly acid, the second slightly alkaline, and the dose of either is half to one mil on alternate days injected into the gluteal muscles.

1.

℞ Antimonii et potassii tartratis, ...0.5;
Phenolis, ...0.0;
Glycerini, ...12.0;
Aquæ destillatæ, ...q. s. ad 30.0.

2. The same as the foregoing with the addition of 0.02 gram of sodium bicarbonate.

For oral administration to children from one to two teaspoonfuls of the following may be given three times a day in water:

℞ Antimonii et potassii tartratis, ...0.32;
Sodii bicarbonatis, ...2.00;
Glycerini, ...
Aquæ chloroformi, ...āā 30.00;
Aquæ, ...q. s. ad 90.00.

Twice the dose stated above may be given to adults. Oriental sore, and relapsing fever also respond favorably to tartar emetic, but in the latter condition salvarsan or neosalvarsan is much more effective. If tartar emetic is to be used in relapsing fever it should be given intravenously, either in the one per cent. solution or in the form of the phenol solution mentioned earlier.

Anesthesia in Hazardous Genitourinary Conditions.—M. Salzer (*Lancet-Clinic*, November 4, 1916) counsels careful preparation of these cases before operation, the outcome depending more on proper management of the anesthesia in genitourinary work than in any other branch of surgery. Barring strictly emergency cases, a functional renal test, preferably the phenolsulphonephthalein, should always precede the operation. If the test is low, rest in bed, increased fluid intake in the form of Vichy or other alkaline water, and careful dieting may improve conditions. The chief measure, however, is thorough alkalinization of the patient. The urine should be made persistently alkaline to methyl red—alkalinity due to ammoniacal decomposition being guarded against. Alkalies are given by mouth, or, if necessary, by rectum, or even intravenously. All water taken by the patient is alkaline. Under this treatment the urinary output shows a remarkable increase, and cases otherwise unfit can be successfully operated in. Saline cathartics may, if required, be used to insure daily evacuation. No cathartic should be given on the night before the operation, but an enema the next morning. Every effort should be made to bring about as normal a condition as possible. The blood pressure should be closely watched. On the morning of the operation, the patient is permitted to drink Vichy water *ad libitum* up to within a half hour before the operation. About an hour before operation one quarter grain of morphine and one one hundred and fiftieth grain of atropine are usually given, or preferably, the morphine given in two

one eighth grain doses half an hour apart. As for the anesthesia itself, local anesthesia occupies a limited field; it should not be used where it would materially lengthen or interfere with the operation. Nitrous oxide-oxygen should alone be used as a general anesthetic. As soon as the patient regains consciousness, Vichy water is allowed, nausea rarely following nitrous oxide-oxygen. Fischer's solution is at once given by rectum by the drop method, and continued as long as it causes no discomfort, and if it does, resumed as soon as possible. If the least evidence of impending shock or oliguria appears, pituitrin hypodermically and Fischer's solution intravenously are the mainstays. Of forty-three consecutive suprapubic prostatectomies—fifteen in patients over seventy years of age—preceded by preparation as outlined above, all but three recovered. In no case following the operation was there enough disturbance of the urinary secretion to cause alarm.

Surgical Uses of Ozone.—George Stoker (*Lancet,* October 21, 1916) reports a series of twenty-one cases, mainly of cavities and sinuses in the long bones, in which the direct application of ozone was employed, and concludes that this agent is a strong and effective germicide; that it is a powerful stimulant to the circulation through the wounded tissues; that it powerfully increases the formation of oxyhemoglobin in the wound; and that, by virtue of these properties, it is a valuable agent in cleaning up old, indolent wounds, and bringing about rapid healing. His cases varied between three weeks and fourteen months in duration before the use of the ozone and were cured in from five days to seven weeks. Ozone also proved very serviceable in disclosing dead bone, foreign bodies, septic deposits, etc., through destruction of the unhealthy granulations. The wounds and sinuses were washed twice daily with boiled water and dressed with dry, sterile gauze. Ozone first produced an increase in the amount of pus which was replaced by clear serum and later by reddish serum, after which healing progressed rapidly.

Treatment of Achylia gastrica.—Albert F. R. Andresen (*Medical Record,* Nov. 11, 1916) gives the indications for treatment under four headings, the removal of infective foci, the treatment of causative or complicating constitutional abnormalities, the treatment of the stomach itself with special attention to its motor function, and lastly the dietetic treatment. Autogenous vaccines should be used, made from infective foci before proceeding to the operative treatment of these foci whether they be in the mouth, nose, throat and accessory sinuses, abdomen, pelvis, or other part of the body. The constitutional abnormalities to be corrected are the anemias, leucemias, malaria, syphilis, tuberculosis, cardiovascular renal disease, rheumatism, alcoholism, etc.

Ferric chloride and calcium chloride are combined with hydrochloric acid by Andresen although no effect upon the gastric secretion follows the use of bitter tonics. Exercise, especially in the fresh air, gymnastics, baths, and change of scene are valuable with the addition of abdominal massage and electricity. A glass of hot water one half hour before meals is cleansing while mineral oil in tablespoonful doses night and morning is of service as a sedative to the irritated gastrointestinal mucosa and to prevent constipation. The diet should be concentrated and should be given in small amounts every two and a half to three hours. Meat is best excluded as tending to putrefaction, and eggs should be likewise avoided as a rule. Gelatin is a valuable protein sparer while milk is an important part of the diet. Buttermilk and artificially soured milk are not well borne. Starches are important and may be given in the form of vegetable soups or purées of potatoes, peas, beans, lentils, spinach, or carrots.

Flaked or shredded cereals, bread, toast, and plain crackers may be given, but sugar must be used cautiously as it may produce acid fermentation in the bowels. Fats and oils while soothing in limited quantities are bad when used in excess. Alcohol and tobacco are strictly forbidden. Approximately between two and three thousand calories a day are required.

Recent Progress in Obstetrics.—Sylvester J. Goodman (*American Journal of Surgery,* November, 1916) says with respect to twilight sleep that not even the most enthusiastic advocate believes or can say that twilight sleep causes painless labors. They say that it causes the mother to forget her pains and not be averse to having more children. If you are an honest practitioner and are not using questionable methods to increase your business, you must admit that Nature causes every mother to forget her pains as soon as delivery is accomplished. You know that this is true. Then why inject into a mother something that you know to be unsafe and which you cannot take away once it is administered? Do you think that anyone in the average town in this State administers real twilight sleep? I know that not one of those practitioners who tells his patients that they are receiving twilight sleep is telling them the truth. How can they give it when there is not one hospital in Ohio equipped to offer the proper carrying out of the Freiburg technic? I know of one eminent obstetrician who says that he uses this method and yet he is so busy that he misses being present at a number of confinements for which he had been engaged. Anyone who has read or studied the technic of administering twilight sleep must at once recognize the manifest absurdity of such procedures when offered as the real thing. These accoucheurs merely inject a dose or two of morphine, and perhaps scopolamine, and call that twilight sleep. The men who are guilty of this deception are plainly dishonest to a woman who has entrusted herself to them at the most critical period of her life. It is not possible for me, at this time, to quote all that has been written for and against this much advertised technic. Suffice it to say that a large majority of honest and careful obstetricians are against its employment and there has been an increasing number of editorial articles in the leading journals denouncing this method as unsafe and unscientific. At the last meeting of the Association of Obstetricians and Gynecologists, held in Pittsburgh, twilight sleep was denounced in no uncertain terms. It was said that twilight sleep was dangerous; and safety first a good slogan.

Management of Labor in Borderline Contractions of Pelvis.—John Osborn Polak (*American Journal of Surgery*, November, 1916) concludes with regard to the management of such conditions as follows: 1. Accurate pelvimetry is absolutely necessary in order to recognize the type of deformity.

2. Pelvimetry without the relative estimation of the size of the fetus is of little value and the most accurate fetometry is the test of labor.

3. Every borderline case should be given a test of labor and this should be conducted in a hospital under the most scrupulous asepsis. All examinations should be made through the rectum. Only in making the ultimate decision as to procedure is a vaginal examination to be made. This is then done with the patient anesthetized and under the strictest surgical technic. 4. Spontaneous delivery will reward patience and vigilance in eighty per cent. of such cases:

5. Pubiotomy is safe in multiparæ with flat pelves of 7.5 cm. or over and in justominor contraction when the true conjugate is over 8.5 cm. and in funnel pelvis in primiparæ. The Dœderlein technic is the simplest and safest.

6. Extraperitoneal section should be elected as the method of delivery when the labor has been prolonged and the membranes have been ruptured for a long time. The classical operation should be reserved for the elective cases, and finally, that no hard and fixed rule can be set down for the management of any case. Each case has to be individualized.

Application of New Wartime Antiseptics to the Surgery of Civil Life.—Charles W. Hennington (*Buffalo Medical Journal*, November, 1916) writes mainly of the hypochlorites, the most widely discussed of which is sodium hypochlorite, often known as Dakin's fluid, that has been modified by Carrel. Dakin's fluid is made by decomposing chloride of lime with a solution of sodium carbonate, and adding to the filtered solution containing sodium hypochlorite enough boric acid to neutralize the excess of alkali. The resulting solution is a balanced mixture of hypochlorite and polyborates of sodium with small amounts of free hydrochlorous acid and boric acid. Two methods of preparing this fluid are as follows: 1. Dissolve 140 grams of dry sodium carbonate, or 400 grams of washing soda crystals, in ten litres of tap water. Add 200 grams of chlorinated lime of good quality and shake well. In half an hour the clear liquid is siphoned off from the precipitate of calcium carbonate and filtered through a plug of cotton. Then add forty grams of boric acid merely to keep it neutral, and the solution is ready for use. It contains 0.5 to 0.6 per cent. of sodium hypochlorite. It does not keep longer than one week. 2. Dissolve 105 grams of dry sodium carbonate in one litre of water. Add 150 grams of chlorinated lime. The mixture is filtered and a measured portion is rapidly titrated with a boric acid solution of known strength, using phenolphthalein suspended in water as indicator, in order to determine the amount of solid boric acid to be added to the rest of the filtrate. It is best to add slightly less boric acid than the estimated amount because any excess is to be avoided. The solution thus prepared is much stronger, containing about forty-five grams of sodium hypochlorite. It must be diluted with six parts of water before using, but it will keep for one month.

Carrel's modification, which now is more generally used, is about 0.5 per cent. in strength and ready for use: Dissolve 200 grams of chlorinated lime in five litres of water, agitate thoroughly and set aside over night in a twelve litre jar. Dissolve 100 grams of dry sodium carbonate, and eighty grams of sodium bicarbonate in five litres of water. Pour the two together and agitate vigorously one minute. In half an hour the clear liquid is siphoned off and filtered through paper. Then test with phthalein powder that it is not alkaline. Remarkable results have been achieved in military surgery by the use of these substances, and it seems but a step to apply them to similar surgical conditions met with in civil life.

Treatment of Mucomembranous Colitis in Children.—Oscar Jaime (*Archivos de Medicina Interna*, July-August, 1916) writes that in many cases the establishment of a proper diet will alone suffice to accomplish a cure. Drugs must be used with care, as their improper use aggravates the situation. Carbohydrate diet is the first therapeutic measure followed by intestinal antiseptics. Sodium sulphate is a drug of great value in this disease, not used as a purgative, but in small doses two to four grams according to the age of the child in a half glass of Vichy on an empty stomach. In older children or adults the sulphate may be combined with the phosphate of soda and given in capsules at meal time. Pain in colitis should not be combated with opium except in unusual cases, on account of the constipation thus produced, but rather treated with belladonna, hot compresses, light massage, and potassium bromide in small doses together with extract of hyoscyamus.

Radium in Carcinoma of Bladder and Prostate.—Benjamin S. Barringer (*Journal A. M. A.*, November 11, 1916) reports nine bladder and five prostatic cases treated with radium. In two of the former there was rapid and complete disappearance of the neoplasm, and three of the prostatic cases have greatly improved. Insufficient time has elapsed to lay claim to a cure in any case. The method of treatment in bladder cases consists in the introduction through the direct cystoscope of 100 to 200 millicuries of radium, screened with 0.6 mm. of silver and 1.5 mm. of rubber and enclosed in a capsule an inch long and one eighth of an inch in diameter. To the end of the capsule a long, double linen thread was attached and allowed to pass out of the urethra to be used for the removal of the radium. The patient was encouraged to hold his urine during the treatment to aid in screening the bladder. If the carcinoma is lateral the patient should lie on the affected side. The exposures lasted up to eight hours. The application was not repeated until all effects of the preceding one had disappeared. In carcinoma of the prostate the application was made by enclosing fifty to seventy-five millicuries in the tip of a four and one half inch, eighteen gauge needle. This was then introduced through the perineum and guided to insertion into the affected lobe by the finger.

Treatment of Flatfoot in Old Patients.—Sigmund Epstein (*Medical Record*, Oct. 21, 1916) states that inflamed flatfoot, especially if complicated by senile osteoarthritis, should be treated by rest in bed with or without plaster of Paris before using Whitman plates. Some old people get most relief from a pad of corn plaster felt, while removal of infective oral foci often gives marvelous results. Tonics, thymus extract, pituitary extracts, and colchicum may be used in appropriate cases. At the menopause in women thyroid extract may be used: hot saline baths and spa treatment are advocated by some. Bier artificial hyperemia or hot air baking is a great pain relieving measure especially in stiff and sore feet after subacute rheumatism. Muscle exercises especially with the circumduction machine is of value, and exostoses may require removal.

Spinal Fluid in Iodide Medication.—Joseph H. Catton (*Journal A. M. A.*, November 4, 1916) reports two lumbar punctures made upon each of five patients under oral iodide therapy, the first to remove as much fluid as possible, the second to determine if the previous removal had increased the iodine in the fluid. In none of the five cases was there even a trace of iodine on either tapping. A second series of observations was carried out upon a single person to whom doses of one gram, increasing to nearly three grams, had been given and followed by a single dose of 16.5 grams. Fluid was withdrawn eighteen minutes and twenty-four hours after the large single dose of potassium iodide. No iodide was found in the spinal fluid. A week later, after no medication in the interim, another single dose of sixteen grams of sodium iodide was given and the spinal fluid subsequently was also found free from iodide. It was evident from these observations that iodide, given by mouth, did not pass into the spinal fluid.

Intravenous Use of Sodium Gynocardate in Leprosy.—Leonard Rogers (*Brit. Med. Jour.*, October 21, 1916) states that the fractionization of chaulmoogra oil yields several different portions, and that with the lowest melting point yields fatty acids the sodium salts of which are readily soluble in water, and relatively only moderately irritant upon hypodermic injection. These salts are also relatively nontoxic for animals when given intravenously. Rogers terms this fraction the gynocardic acid fraction and the sodium salt sodium gynocardate, since this acid forms the greatest proportion of those present. This sodium gynocardate may be given intravenously to man in leprosy in the form of a two or three per cent. solution to which one half per cent. phenol has been added, and which has been sterilized in an autoclave. Doses of six to fifty mgm. have been given to man without any toxic effects. Following such doses there is often a definite local reaction and sometimes fever, after the subsidence of which the affected tissues are softer than before and the nodules, if present, diminish in size. These results have not been obtained from the subcutaneous use of the drug, even in much larger doses. Some twenty cases of leprosy have so far been treated by Rogers with intravenous administration of the sodium gynocardate and in all in which it has been possible to carry out the treatment for a sufficient time there has been very marked improvement with healing and disappearance of the local lesions, disappearance of the bacilli from open lesions or tubercles, return of sensation in anesthetic areas, and restoration of function in paralyzed parts. The drug seems to be more effective in cases of the anesthetic variety than in the tubercular type, but in both the results are very promising. The use of the drug intravenously is a marked advance upon the older method of subcutaneous injection since it is much more effective and is free from the production of pain so that the patients will continue treatment without complaint.

Injection of the Gasserian Ganglion.—Lewis J. Pollock and Hollis E. Potter (*Journal A. M. A.*, November 4, 1916) state that the technical difficulties and the high mortality associated with operations for the removal of the Gasserian ganglion have led to the attempt to inject this structure with alcohol through the unbroken tissues. The authors have experimented with several methods suggested and have come to the conclusion that that of Härtel is the most certain of success. This method can be rendered more certainly successful and easier if combined with fluoroscopy during operation. The anterior portion of the petrous part of the temporal bone casts a shadow, with the skull viewed laterally, which forms a guide for the passage of the needle through the foramen ovale and the course of the needle itself can be watched by its own shadow. The perfected technic is described in full in the paper, and its accuracy is proved by the results of experiments upon both sides of fourteen heads of cadavers.

Magnesium Chloride in the Treatment of Wounds.—Marchak (*Presse médicale*, October 9, 1916), reports excellent results from the treatment of wounds by Delbet's magnesium chloride method, which aims to augment the defensive powers of the body by stimulating phagocytosis. The wound is first opened up so that it can drain spontaneously without any special drainage device, drains interfering with wound disinfection, as they are themselves foreign bodies. It is then irrigated daily with magnesium chloride solution, and a large wet dressing applied. In severe cases instillation of magnesium chloride solution by the drop method is practised and daily subcutaneous injections of the same solution, as in saline hypodermoclysis, are given. Marchak receives the wounded six to ten days after the injury, when the wounds are freely suppurating, but by the procedure mentioned succeeds in disinfecting them within six to eight days. In a few days the wounds acquire a reddish color and the pus becomes thicker, viscid, and transparent, and then disappears. When the wound has become red, with a tendency to bleed, and the temperature has been normal for four or five days, Marchak closes the wound without drainage. By this method a large thigh wound about a foot long was closed in nine days, with a soft, linear scar. Similar results were obtained in a wound of the thorax after rib resection, in a large wound of the buttock, and in the case of a thigh stump closed secondarily after amputation for arthritis of the knee.

Miscellany from Home and Foreign Journals

Elimination of Strychnine by the Kidneys.—R. A. Hatcher and M. I. Smith (*Journal of Pharmacology and Experimental Therapeutics,* October, 1916) report from experiments on dogs that strychnine, injected intravenously, often appears in the urine within a few minutes, though only in traces. Producing diuresis by intravenous injection of sodium sulphate, however, caused elimination of strychnine in the urine at a rapid rate. They deem it possible that diuresis may contribute to the successful treatment of cases of strychnine poisoning where the amount taken has been only slightly in excess of the minimum lethal dose or where the absorption of the poison is unusually slow. Where very large amounts of strychnine have been taken, diuresis can only play a minor therapeutic role, artificial respiration with ether and chloroform anesthesia, remaining the chief measures.

Bacteriological Findings in Cerebrospinal Fluid in Poliomyelitis.—John W. Nuzum (*Journal A. M. A.,* Nov. 11, 1916) states that contrary to the general experience of others he has been able to cultivate a polymorphous coccus from the spinal fluid in forty-five out of fifty cases of poliomyelitis. The organism occurred as a minute, Gram positive diplococcus or streptococcus, identical with that cultivated from brains and cords in fatal cases. In old cultures it assumed a larger form. It was infectious for monkeys, rabbits, and lambs, producing flaccid paralysis and typical histological lesions in the central nervous system. It could be isolated from the spinal fluid of such animals after infection from intraperitoneal or intravenous inoculation. Cultures up to the fifth generation and others two weeks old were infectious. Control cultures from spinal fluid of other diseases were negative so far as this organism was concerned. Used as antigen, cultures of this organism caused hemolysis in the majority of cases tested. Controls were negative.

Dysmenorrhea.—J. W. Kennedy (*American Journal of Obstetrics,* July, 1916) lays stress on a most careful investigation of the case in the diagnosis of this condition, which is surgically much abused, and the etiology of which in many instances remains in doubt. The local condition in dysmenorrhea is greatly influenced or even dominated by the particular type of the patient. Thus, obstructive mechanical conditions may coexist with normal menstruation, while in the highstrung or nervous type of woman dysmenorrhea will result from a condition of the pelvic organs which would yield a normal menstrual flow in other women. Kennedy recognizes only two general forms of dysmenorrhea, the obstructive and the spasmodic. Most cases usually classified as obstructive are in reality spasmodic, as is frequently evident when we attempt to dilate a supposedly stenosed cervix. Practically all cases of true obstructive dysmenorrhea result from actual tumors or an amputation or faulty repair of the cervix. Spasmodic dysmenorrhea, comprising the larger proportion of cases, is often relieved by dilatation; this is not the result of the production of a more patulous canal, but is due to relief of muscular spasm. In most instances a squeezing of the dilator by the cervix is noticed as the instrument is withdrawn. In the most obstinate form of dysmenorrhea, that found in patients with an infantile uterus and often associated with scanty menstrual flow, the best results are obtained from insertion of a stem pessary, but this measure is not without danger from infection. Antipyrine will relieve painful menstruation oftener than any other drug. Where the condition is due to or aggravated by ovarian congestion, the patient is relieved by recumbency or other means depleting the pelvis.

Simplified Technic in the Preoperative and Postoperative Care of Patients.—John F. Ranken (*Bulletin of the Department of Public Charities,* October, 1916) advises the administration of sodium bicarbonate solution with or without lactose, in the proportion of one dram of sodium bicarbonate to one pint of cold water, just as soon as the patient enters the hospital. This practically does away with postoperative nausea. Castor oil should be given in the dose of from one to two and a half ounces without the use of an enema of any sort. Morphine, if given immediately before operation, prevents acidosis; if given after, it produces it. The administration of ten grains of quinine hydrochloride in a retentive enema of sodium bicarbonate solution every six hours for twenty-four hours does away with postoperative pain. On the morning of the fourth postoperative day six drams of castor oil are administered, and from then on the bowels are looked after every second day.

Defense of the Child against the Tubercle Bacillus.—Francis M. Pottenger (*Journal A. M. A.,* November 11, 1916) asserts that a nonspecific cellular and humoral mechanism of defense protects the young child and infant against bacterial infection. This is mainly accomplished by the lymphatic system through the tonsils, adenoids and Peyer's patches, and the deeper lymph nodes. With the destruction of the organisms, including tubercle bacilli, in these structures there arise specific defensive substances, which are increased as age advances and new invasions occur. If the tubercle bacilli are not all destroyed in the lymph glands they are held captive and set up a local tuberculous focus. Before the development of the specific protective agents tuberculosis is confined to the lymphatic tissues except in massive infections in which the organisms pass through the glands into the blood stream and cause a general tuberculosis. After the acquisition of specific defense the bacilli are attacked by the fixed cells and either destroyed or prevented from spreading by fibrosis and encapsulation, or ulceration and discharge. These facts show the great importance of the lymphatic structures as protective organs, and the consequent value of their preservation to the child unless there is absolute need of their removal.

Observations on Dysentery.—William Magner (*Lancet,* October 21, 1916), states that from a study of a large number of cases of dysentery he found a considerable proportion of latent amebic cases occurred in which the ulcers were confined to the cecum and produced no symptoms. These cases sometimes became active, but their greatest danger was as foci for the infection of others. Incomplete treatment of amebic dysentery proved dangerous for the same reason, since it often led to the production of latent cyst carriers. In a fair proportion of both bacillary and amebic cases there was a secondary invasion of the ulcerated intestinal wall by other organisms which intensified both the local and the general symptoms. Such secondary invasion was often the cause of the fever of the later stages of the amebic form, and in both types secondary invaders at times produced a septicemia. Agglutination tests showed this reaction to be a valuable means of diagnosis when it was distinctly positive in a dilution of one to 100 or over. Such a reaction was invariably present in the Shiga infections after the first week of the disease. Serological tests also showed that certain organisms which usually led a saprophytic existence in the intestine might produce specific reactions when they had invaded the intestinal ulcers. Finally, it was shown that the mannite fermenting dysentery organisms might exist in the intestine in a latent form and be present in the stools. In such cases the agglutination reaction served to prove their lack of activity in the host.

Diagnosis of Pulmonary Tuberculosis without the Stethoscope.—H. Longstreet Taylor (*St. Paul Medical Journal,* September, 1916) maintains that in the diagnosis of incipient pulmonary tuberculosis physical examination is of little value, as the signs are not pronounced until actual destruction of pulmonary tissue has taken place. A tentative diagnosis can be made from the history and symptoms, and should be made, at least in the physician's mind, before the chest is examined. Given a young adult with vague, indefinite indications pointing to the disease, the chances are decidedly in favor of its being present. Absence of tubercle bacilli from the sputum proves nothing. Careful exclusion of other toxemic conditions that may simulate tuberculous intoxication is, of course, indicated. The various possible modes of onset of the disease, other than the hemorrhagic, should be borne in mind. Thus, in cases with the "neurasthenic" onset, nervous depression, insomnia, and gastric disturbances are often the first symptoms. In other instances the onset is characterized by anemia of chlorosis, obstinate pleurisy, or unresolved pneumonia. A temperature curve is of distinct diagnostic value. A slight evening rise of temperature, possibly subnormal in the mornings, with a pulse rate at all times accelerated, and slight debility, in a patient somewhat short winded, easily tired, and with a tendency to what he calls dyspepsia, practically permits of a diagnosis especially in the presence of a slight hacking cough in the morning. Hoarse patients with a cough persisting over two weeks should be suspected of tuberculosis: the larynx may exhibit only an acute catarrh, but soon after infiltration of the arytenoids or a characteristic swelling and serration of the interarytenoid region will appear. The cough in the morning may consist of a few short coughs, with or without any expectoration. Other suspicious auxiliary signs are slight loss of weight, a persistent tickle in the throat causing uncontrollable cough and slight hoarseness, sweating at night, and protracted convalescence from an acute disease. Where a suspicion exists, skilful physical and x ray examinations, a tuberculin test, and especially, an autoinoculation test are in order. If none of these proves decisive, the patient must be observed for a time to insure correct diagnosis.

Congenital Urticaria pigmentosa.—George Pernet (*British Journal of Children's Diseases,* October, 1916), in presenting a child seven months old, points out that the long axes of the oval pigmented areas are mainly arranged transversely, that is, in the lines of cleavage. A wheal is produced on pressure. There is, usually, an enlargement of the various lymphatic glands, but the child reported showed only a slight amount of adenitis about the groins. Liquor magnesii carbonatis and sodium bicarbonate mixture and a lotion of sanitas one to eight were ordered. This led to a distinct improvement in the itching. The histological appearances in these cases are peculiar—and may be said to be pathognomonic, i. e., numerous mast cells arranged in columns and rows. Urticaria pigmentosa may be a manifestation of congenital syphilis, although in this case the Wassermann reaction was negative. In the mother the reaction was slightly positive.

Chronological Peculiarities of Restoration of Function in Injured Nerves.—Chartier (*Presse médicale,* October 9, 1916) presents a diagram showing by means of curves the chief clinical and electrical manifestations of returning function in injured nerves, whether this restoration is spontaneous, or follows liberation or suture of the nerve. The first sign of returning function, which appears before an appreciable change in the electric reactions, is a return of muscular tonicity. Next appears sensitiveness of the muscle to the faradic current. Its excitability to the galvanic current simultaneously rises. Only some time later are the first traces of voluntary contractility of the muscle noted, and immediately after, the excitability of the nerve to the galvanic current. Next the nerve becomes sensitive to the faradic current, and finally, after a distinct interval, likewise the muscle itself. By the time the motor power of the muscle has returned to normal, the nerve is normally irritable to the galvanic and faradic currents; yet the excitability of the muscle itself by these currents remains subnormal, and its contraction does not regain the normal briskness for many months or even more than a year. In the case of a suture of the radial nerve above the level of the branch to the supinator longus, performed soon after the injury, and under favorable conditions, with subsequent systematic electric treatment, returning tonicity may be noted after the twentieth day, beginning voluntary motion after the hundredth, and complete restoration of motor power about the five hundredth.

Intraspinal Administration of Mercurialized Serum.—Livingston Hunt (*Bulletin of the Department of Public Charities,* October, 1916) describes the treatment as follows: Fifty c. c. of blood is obtained from the patient's arm and collected in a sterile cylinder four hours after an intravenous injection of salvarsan. The blood is slanted, the clot separated, and then left over night in the ice box. The next morning a sterile centrifuge tube (containing about thirteen c. c.) is readily filled with clear serum and centrifugated for five minutes. A few red blood cells collect at the bottom of the tube and the supernatant fluid is poured into a sterile, freshly washed cylinder. To this one fiftieth grain mercuric chloride is added. The mercuric chloride is prepared as follows: One gram of Merck's mercuric chloride is weighed out carefully and added to a litre of sterile, distilled water which is then brought to a boiling point. This completely dissolves the mercuric chloride. Of this solution 1.3 c. c. contains approximately one fiftieth grain mercuric chloride. The mixture is brought up to thirty c. c. with sterile water and inactivated for half an hour at 58° C. It is then injected within an hour. The injection is given with the patient lying down on his side. A thirty c. c. syringe is used and the fluid allowed to run in by gravity. The foot of the bed is elevated for an hour after the injection, and phenacetin is used liberally for pain.

The Luetin Reaction.—William Fletcher (*Lancet,* October 21, 1916) reports a series of 130 supposed syphilitics tested with Noguchi's original preparations. Thirty-three per cent. of the primary cases gave positive reactions; fifty-seven per cent. of the secondary cases; and seventy per cent. of the tertiary ones gave a similar reaction. Only one of six doubtful cases gave a positive response to the test. One hundred and nine patients of this group were subjected to both the luetin and Wassermann tests, with the following results: In seven cases of primary syphilis there were six positive Wassermann reactions and only three positive luetins. In thirty-six cases of secondary syphilis the positive reactions were, respectively, twenty-nine and twenty-four. And in sixty-six tertiary cases they were, respectively, thirty-five and forty-eight. These figures showed that in the first and secondary stages the Wassermann reaction was more frequently positive than the luetin test, while the conditions were reversed in the tertiary stage. There was no agreement between the results of the two tests, other than that of chance, the results of the two being the same in fifty-six and at variance in fifty-three. It was evident that the substances causing these reactions were not the same. Of the total of 109 cases thus tested ninety-nine responded positively to one or both of the tests, ten being negative to both. Two of the negative cases were in the secondary and eight in the tertiary stage. These two tests were then applied to a group of eighty-two cases other than syphilis. In this group there were twenty-two cases of leprosy, seven of which were probably syphilitic. Of the whole number of lepers thirteen gave positive Wassermann reactions. All of the eighty-two cases reacted negatively to the luetin test except one who had had syphilis ten years before, while nineteen reacted positively to the Wassermann. More positive results from the luetin tests in the group of syphilitics would have been obtained if it had not been that the luetin had undergone some deterioration. It was concluded that the use of the two tests in conjunction was of great diagnostic value, since in the great majority of cases one or the other was positive. The negative luetin test had the disadvantage of not excluding syphilis, especially in the first two stages.

Internal Glandular Extracts in Mentally Retarded Children.—Walter Timme (*Bulletin of the Department of Public Charities,* October, 1916) gives the histories of several cases of this nature. In one case the symptoms pointed to an overacting thymus. This patient was given thyroid and showed improvement. Another showed a combination of an underacting pituitary with an overacting thymus. In this case pituitary was administered and thyroid given later. A third showed a marked status thymicus; she had been put on thyroid, which had been continued too long.

Separation of the Buttocks.—John C. Silliman (*Journal A. M. A.,* Nov. 11, 1916) states that when examination or treatment of the anus or its region has to be made in the absence of an assistant, much trouble is often encountered by the falling together of flabby buttocks. This can be overcome easily and effectively by applying a strip of adhesive plaster two inches wide transversely across each buttock for about six inches, beginning about an inch outside of the anus. The free ends of the strips may then be tied together in front by means of two pieces of bandage.

A Study of Chorea.—Isaac Arthur Abt and A. Levinson (*Journal A. M. A.,* November 4, 1916) reports material comprising a total of 226 cases occurring between the ages of three and one half and eighteen years. This group constituted about two per cent. of all children treated during the period of the study. Between five and fourteen years were the ages of the most frequent occurrence of chorea, and females were twice as numerous as males. Contrary to general opinion the relation of the disease to rheumatism and rheumatic manifestations was not at all marked—only thirteen having had a definite history of rheumatism. Tonsillitis also did not bear an important relation to the disease, but infectious diseases were observed to precede the onset of chorea in a large proportion of cases. There was, however, no apparent causal relation of these to the disease. Again, somewhat contrary to opinion, the disease was found to have a decided tendency to localize in one extremity or on one side of the body, or to be more marked on one side than on the other. The most frequent complication was endocarditis, though this was not at all constant. Two to eight weeks was the average duration of the disease with extremes of one day to over one year. Recurrence was not infrequent and several cases had more than one recurrence. Rest in bed, isolation, baths, and administration of the salicylates seemed to be the most satisfactory treatment. Arsenic did not seem to have any effect on the disease. Treatment apparently did not influence the tendency to recurrence.

Proceedings of National and Local Societies

JOINT MEETING IN PEDIATRICS.

PEDIATRIC SECTION, NEW YORK ACADEMY OF MEDICINE; NEW YORK STATE SOCIETY; NEW JERSEY PEDIATRIC SOCIETY; PHILADELPHIA PEDIATRIC SOCIETY; NEW ENGLAND PEDIATRIC SOCIETY.

Held in Boston, November 4, 1916.

Dr. ALEXANDER H. EASTMAN, President, New England Pediatric Society, in the Chair.

Medicoeducational Problems in the Treatment of Atypical Children.—Dr. G. HUDSON MAKUEN, of Philadelphia, said that the mind or personality of the individual distinguished him from a mere laboratory receptacle, making psychology as necessary a study as physiology, anatomy, or chemistry. Upon psychical health physical health depended to a certain extent. To physicians who had the care of children, the idea that the prevention of disease was even more desirable than the cure should have a strong appeal. Finally habits acquired during infancy and early childhood were responsible for many of the diseases of subsequent years. Medicoeducational methods were especially applicable to the treatment of atypical children, and to be curative in every case should be instituted several generations before the birth of the child. Heredity played a large part in the development of a child, but environment was even more important and was subject to change and improvement. Education and training formed the major part of the child's environment. The period that came prior to the so called school age was the most neglected part of the life of a child. Fixed habits were formed in the first years of life. While the mind of a child had a physical basis, yet his mental activities determined to a great extent the character of this basis by regulating its development, and so it was that the general physical condition of the child might be influenced for good or ill by the character of his mental and emotional activities. Medicoeducation therefore as a preventive measure should be applied during infancy. Nervousness was common in children and its treatment should be first preventive and then curative. Child psychology taught that the brain was most susceptible to physical and functional development. During mental development the cerebral convolutions increased enormously in number and the cortex underwent a corresponding increase in surface growth. In childhood the association fibres of the brain were rudimentary and their full functional powers were attained only after years of growth and development. A notable difference between the mentally normal and the abnormal child appeared in the fact that the one developed automatically, while the other seemed to halt or sometimes to be retrogressive. The physician should aim to help atypical children in both physical and mental development. Medicoeducational methods should aim, not to remake the child, but to make the "absolute best" of what had already been made. Preventive treatment was applicable in the earliest infancy and consisted largely in an attempt to control the child's physical activities through a careful direction of his psychical and emotional activities. If the child was normal physically, this treatment should result in the development of normal physical and emotional faculties, but if the child inherited physical abnormalities, such as cleft palate or other irregularities of structure, surgery and some form of medication might be indicated in addition to the psychophysical training. Punishment should never be necessary, except perhaps at the very beginning and before the child was mentally susceptible to medicoeducational measures. It was said that there were upward of 300,000 stammerers in the United States alone, and if this vast army of defectives could have had the right kind of early training there would be few if any stammerers to contend with, and what was true of stammering, was true of similar and allied nervous diseases. The personality of the child was modified and moulded by what some one had called the reflex influences of its own acts and impressions. To make any act or gesture or mode of speech or motion habitual through deliberate repetition, was to stimulate in the personality the appropriate moral quality or emotion of which such an act or gesture was the expression. The Japanese had a theory that for a man to be what he would like to be, it was only necessary for him persistently to act the part. Doing things with purposeful intent was found to have a greater educational value than doing them carelessly even in play. The play instinct was an important factor in child development, but it was at the present time the most overworked of them all, both in the home and in the primary school. What might be called the work instinct was equally important and was now being greatly neglected in the training of children. The child should be taught to do things, not because they were easy, but because they were right, and the greater the difficulty in doing them, the greater the educational value. Atypical children should not be coddled, but encouraged, and like plants of slow growth and development, they might be forced. This might be done by furnishing favorable conditions for growth and development and by directing their physical activities into the right channels. Many a nervous child immediately began to improve physically as well as mentally when well directed pressure was brought to bear upon him in psychophysical education. This was due to the fact that the child was wearing himself out nervously by his aimless and ill directed activities, and judicious training in such a crisis often resulted in a much needed rest to both body and mind. It was said of older people that it was not work but worry that killed, and they had been inclined to overlook the fact that this was true, even in young children. The satisfaction of having done constructive work in a successful manner was not confined to mature men and women, but might come very early in the lives of children. The so called hereditary tendencies were frequently aggravated and encouraged by faulty parental attitudes, which were usually the result of ignorance,

selfishness, and overanxiety. The most difficult thing in the treatment of atypical children was to control and direct this parental influence and enlist it in behalf of the child's welfare. In some cases the parents were hopeless and it became necessary to remove the child from home surroundings. In summing up, it might be said that correct postural attitudes and good respiratory, phonatory, and articulatory habits should have a conspicuous place in all medicoeducational methods, because of their esthetic value and because they tended to confer greater self respect, self reliance, and self control.

Intestinal Venous Stasis.—Dr. Fenton B. Turck, of New York, declared that synthesis of organic compounds, and the role of the physics of colloids in biology had created a new concept of normal and abnormal conditions in the body. He had been studying experimentally the factors involved in the permeability of membranes in the living organism. The membrane filter was itself colloidal in character, and it determined the rate of diffusion of the colloidal suspension that filtered through it. In the study of the phenomena of the passage of the colloids it was found that such substances as the white of egg passed unchanged through animal membrane. The study was involved in considerable obscurity owing to the difficulty of identifying the colloids after filtration. The speaker had demonstrated by experiments on animals that emulsion of bacteria, such as the colon bacilli, injected into the intestines of a fetal animal, would rapidly diffuse through the membranes and tissues. By the use of appropriate staining methods he had been able to determine the rate of diffusion and the route by which it took place. That the intestinal tube was permeable to intestinal flora he had proved some years before He had also shown that the degree of this invasion was greatly influenced by the splanchnic circulation; interference with the splanchnic circulation altered the character of the intestinal wall and rendered it permeable to all forms of bacteria. When bacteria were injected into the intestines of the fetus, distinct routes were taken from any depot along the entire tube. Thus the kidney or liver was the first involved when the injection was made into a certain part of the intestinal tract. Microorganisms injected into the intestines of a fetal animal rapidly diffused through the mucous wall of the intestine, between the glands, into the areolar tissue, and then along the wall of the intestines between the muscle coat and the mucous membrane. At this point many of the microorganisms underwent bacteriolysis. In the newborn there was no barrier, no arrest of passage by the mucosa labyrinth; a wall impervious to bacteria had not yet been sufficiently formed there, nor apparently were antibodies adequately generated, since so far they had not been needed. As the body grew, the tissues became less porous to bacteria. When disturbance of the splanchnic circulation and muscular atony of the wall of the alimentary tract were produced, then a reversion to the fetal state of the intestine followed, and the body needed to be protected from the toxins formed in the zona transformans, and antianaphylaxis was, it might be said, automatically established. The passage of bacteria took place from the intestinal tract into the intestinal wall between epithelial cells and not through or into the cells and between the muscle cells of muscular mucosa. As rapid bacteriolyses were seen to take place in this submucous zone, he had named it the zona transformans. The degree of permeability of the intestinal wall in a living subject was increased by a number of factors, namely: 1. Mechanical obstruction of the intestines; 2, an interruption of the circulation sufficient to cause atony; 3, an interference with the nerve supply; 4, a number of other pathological conditions. In order to induce permeability, fundamental changes in the flora of the individual and in the physiology of the organ must be induced; among the means of bringing this about were thirst, hunger, overfeeding, and shock. Autolysis of the tissues took place after venous stasis, with a resulting asphyxia of the cells. The muscle cells underwent the characteristic changes of Zenker's degeneration, with atony and dilatation. Ligations of the lower portion of the intestinal tract were not so evident in causing bacterial migration as in the upper segments. No bacteria seemed to enter the blood or lymph vessels. The feeding experiments further showed that fat and fatty acid increased the diffusion rate of the intestinal bacteria through the intestinal wall and hastened the fatal termination. Six monkeys fed with small squares of bread fried for thirty minutes in cotton seed oil, in addition to the usual vegetable feeding, died in from three to six weeks and showed an increase in the filtration of bacteria in the tissues. Lesions resulting from disturbances produced in the upper intestinal tract were shown to be more quickly fatal than those made in the lower intestinal segments. The passage of the living bacteria into the tissues caused a reduction (by absorption) of the protective bodies (antiferments), and resulted in autolysis. A study of the clinical picture as seen in the human being paralleled these findings. Stasis induced by frequent feeding caused precipitation and delayed digestion, and resulted in fractional digestion and the production of fatty acids. The changes produced in the cells were not due to lack of oxygen or increased carbon dioxide, but to acidosis, the result of fatigue to the muscle cells and asphyxia of those cells from venous stasis. This resulted in atony and permeability of the muscle wall and diffusion of bacteria and of the fractional protein products. Upon bacteriolysis and proteolysis anaphylaxis ensued, in other words, acidosis. The symptoms of this condition in its acute form were shock, distention, prostration, convulsions, etc. The symptoms of the chronic condition were wasting, marasmus, anemia, etc.

Treatment must have for its object the reduction of fatigue of the visceral muscle, prevention of fatty acid intoxication, intestinal retention, and absorption of intestinal flora; it must also correct the acidosis, reduce venous stasis, increase immunity, and maintain nourishment. Thus, in the acute cases, gastric and colonic lavage; lavage with weak nitrate of silver, followed by sodium bicarbonate; demulcents and venesection, followed by infusion of sodium carbonate solution, were indicated. In extreme cases the transfusion of autoserum might be indicated, also the continuous bath. In the moderate and chronic cases gastric lavage and colonic lavage, with gentle pneumatic gymnastics, were indicated.

together with demulcents, oil of cloves, and vaccines. The food should be reduced to the minimum fineness of particles, the interval between meals should be prolonged to the maximum point within the caloric safety, and regular feeding periods should be established to conform to the curve of muscle work and relaxation. Foods rich in mineral salts should be provided, such as vegetables steamed and made into a purée. The intake of fat should be reduced to a minimum; heated and stale fat should be prohibited. No extractives were allowed, though in older children they might give extract of fresh meat. For a time the total protein intake might be reduced. The medication consisted of alkalies by the stomach and an analgesic mixture. The object of the demulcent such as Irish moss or liquid petrolatum was to prevent the passage of bacteria through the intestinal wall. Absorption of the bacteria might be favored by the administration of fuller's earth, charcoal, or very fine bran. If laxatives were required, phenolphthalein and calomel might be given.

Epidemiology of Bacillary Dysentery.—Dr. G. W. SMILLIE, of Boston, had made a study in connection with the work of the Floating Hospital. That there was need of such a study was evidenced by the fact that the incidence of bacillary dysentery was greater than that of more feared and more widely advertised children's diseases, such as poliomyelitis, and among children the death rate was equally high. While the methods of treatment of bacillary dysentery had long occupied their attention, as well as bacteriological study of the disease, the mode of transmission had excited only indifferent and random speculation. The Floating Hospital furnished most favorable conditions for a study of this kind, because the victims of bacillary dysentery were usually infants under fifteen months of age; their activities were limited; they did not travel much, and therefore they came into contact with few people. They also ate but one or at most a few articles of food. Thus it was comparatively easy to trace the infection in a baby under one year of age, but after a child could walk it became most difficult. Other conditions favoring an epidemiological study of bacillary dysentery were the facts that the disease was clear cut, that the bacilli could be isolated from the stools, and that specific agglutinins developed in the blood of the patient. The fact that the bacillus was found in the feces only and not in the other excretions of the body made it evident that every case represented some short path between the infected feces of the patient and the mouth of the victim. It was known that the incubation period of adult dysentery was from three to seven days, and that the disease was one of summer incidence, being most prevalent in July, August, and September, and, finally, that bacillary dysentery had a preference for the children of the poor. In addition to this knowledge they had records of all cases that were reported to the city boards of health, thus bringing out nests of infection in all parts of the city. A spot map was made of all the cases of last year for purposes of comparison with this year. A record was kept of the daily maximum and mean temperature, and of the relative humidity for the whole summer, of the nationality of the parents, housing and home conditions with reference to sanitation, and of all the activities of the case for two days before the symptoms of the disease developed. In all, seventy-nine cases were studied, forty-nine being house cases and twenty-six related cases. While seventy-five cases were obviously insufficient as a basis for definite conclusions as to the influence of temperature and humidity, there seemed in this series to be no relation between high temperature, high relative humidity, and the case incidence. The case incidence seemed to be more closely related to flies than temperature, for the hot weather was almost over before there were many cases of the disease, and reports of new cases continued to come in well into September, though the humid weather had passed. The families chiefly afflicted were not the illiterate foreigners, but the neglectful, poorer American family. This was not attributable to the fact that the foreigners were more cleanly, sanitary, or intelligent than American parents, for in truth they were very much less so. It seemed to be due to the fact that most foreign mothers nursed their infants. Only one case occurred in a nursing baby, nursed only during the night, and fed with condensed milk during the day. Though bacillary dysentery was ordinarily a disease of poverty and filth, these were not necessary accompaniments, for the disease might be found in the better portions of the city. To estimate the relation between bacillary dysentery and housing conditions a score card was devised somewhat similar to that used for scoring dairies. In all, forty-one homes were scored; the highest score was ninety-four per cent. and the lowest fifteen per cent. The average score for cases of bacillary dysentery that were due to direct contact was only forty-eight per cent. The average score of cases that were a source of infection to others was forty-one per cent. The average score of cases due to infection from food was fifty-nine per cent., and the average for cases for which no source of infection was found was seventy-one per cent. An important fact with reference to the contact cases was that many were in the older members of the family, in whom the disease showed itself in a mild form. Undoubtedly many cases of summer ptomaine poisoning were truly bacillary dysentery, which might become a great menace to the community, particularly to the babies, for as this investigation showed, a mild adult case might readily infect a baby with fatal results. In almost every dirty, unsanitary house which the speaker inspected and in which the sick child remained for more than one week, there resulted a contact case. There was evidence that four babies contracted bacillary dysentery in the hospital wards, for each child was admitted with quite a different diagnosis and did not have the disease until seven to ten days after admission. These were the only contact cases that occurred in the hospital, though virulent bacillary dysentery cases were on board all summer. Since extraordinary care must be exercised to prevent cross infection, no child with bacillary dysentery should be admitted to a hospital unless all facilities for isolation were provided; the most rigid precautions were necessary, particularly fly exclusion. The tenement mother was usually careless in protecting her infant's

stools from flies, as the diapers were seldom boiled, and since flies were so abundant and screens almost unknown, it was extraordinary that more cases were not transmitted. There was a Shiga epidemic last summer that gave an excellent example of the various modes of spread of the casual case of dysentery. The epidemic originated with the two year old son of a dairyman in Haverhill. The source of this infection was probably an ice cream cone eaten in Lawrence. The father, mother, and one other child contracted diarrhea; the father, being only moderately prostrated, kept on his work in the dairy. The milk of this dairy was sold almost exclusively to the Deaconess's Home, a fresh air farm for children between the ages of seven and fourteen years.

In this institution about twenty cases developed out of a total of seventy children. This epidemic began on July 22d, and on July 27th, the children were all sent home. One went to Pine Heights, Dedham, became seriously ill, and after five days was taken to the hospital, where she died. This child's brother and two sisters also became ill. The dejecta were thrown into an open privy without disinfection. A neighbor who came in to assist in the care of the children carried the infection home to her husband. A child living across the street contracted bloody dysentery and died within a few days. About the same time three adult members of one family living about one hundred yards away contracted severe dysentery which persisted for a few days only. The evidence seemed to point to flies as carriers. A case developed in the house adjoining to that in which the first child, the one coming from the Deaconess's Home, lived.

Dr. Henry I. Bowditch congratulated the previous speaker on the work he had accomplished and the results he had attained. It might be of interest to know the results of their study of the bacillary cases during the past three summers, since they were especially interested in dysenteries. In 1914, seventy-nine cases came under their observation, of which sixty-eight per cent. gave a positive Flexner organism; in 1915, there were seventy-five cases, eighty-five per cent. of which showed the Flexner infection; in 1916, there were sixty-four cases, and of these eighty-eight per cent. showed the Flexner infection. In three fourths of the cases the bacteria were recovered from the stools and in others at autopsy, and in a certain few the diagnosis was made by finding the agglutinins. At the same time they had constantly tried to find how much of a factor the gas bacillus or Bacillus welchii was. Bacillus welchii was found not to play an important part. It disappeared quickly in the early course of the illness and was frequently seen to appear later when other foods were given. In 1914, a closer investigation than usual of Bacillus welchii was made, and resulted in finding it in eleven per cent. of infectious conditions; in twenty-seven per cent. of digestive disturbances; in twenty-eight per cent. of malnutrition cases; and in twenty-eight per cent. of normal cases. The infectious cases were studied closely, while the others were picked at random. They felt at present that the Flexner organism was the main etiological factor, and that the gas bacillus, was a complicating factor, not the main etiological factor. This was different from the stand taken some years ago. On the Floating Hospital when a case was entered with the clinical picture of dysentery, the treatment was to keep the child on water for the first twelve hours, and then place it on a food with a high percentage of carbohydrates and moderate protein, for instance, fat 0, sugar 6, and protein 12; this food was usually given in the form of a fat free milk with sugar added. This was continued if the gas bacilli were not present, but when the gas bacilli did occur, the carbohydrates were diminished.

Book Reviews

[We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.]

Practical Bacteriology, Blood Work, and Animal Parasitology. Including Bacteriological Keys, Zoological Tables, and Explanatory Clinical Notes. By E. R. Stitt, A. B., Ph. G., M. D., Medical Director, U. S. Navy; Graduate, London School of Tropical Medicine, etc. Fourth Edition, Revised and Enlarged. With 4 Plates and 115 Other Illustrations Containing 505 Figures. Philadelphia: P. Blakiston's Son & Co., 1916. Pp. xvii-497. (Price, $2.)

The need for a fourth edition of this practical manual testifies to its value as a handy reference book for the laboratory. It is divided into four parts, devoted to bacteriology, hematology, parasitology, and clinical pathology. The subject matter is elementary, but complete and well arranged. The chapters on animal parasitology are of particular value, especially for those who are interested in tropical diseases. Intended primarily as a concise pocket manual for laboratory diagnosis in the Government service, this work has developed into a convenient reference book suitable for general laboratory work. It is to be especially recommended to those contemplating membership in the army or navy service.

Studies in Immunization Against Tuberculosis. By Karl von Ruck, M. D., and Silvio von Ruck, M. D. New York: Paul B. Hoeber, 1916. Pp. xvi-439. (Price, $4.)

The writers of this volume have long been known for their work in the prevention and cure of tuberculosis. Unfortunately, most of their papers have appeared in various medical journals and in reports, and are therefore more or less inaccessible to the general reader. The present volume is the more welcome in that, beside giving the latest views and experiments of the authors, it renders unnecessary the reference to their many previous scattered writings. The main theme in this book is the immunization method in tuberculosis, viewed as a prophylactic and also as a curative agent. The authors do not hold that vaccine is a specific which will cure any and every case of tuberculosis indiscriminately; but they do show that in their hands and in those of many other physicians, vaccine has proved of undoubted value when the cases were carefully selected and other methods of treatment were not neglected. The book consists of three parts, the first dealing with theoretical considerations on the tuberculosis problem in general, immunity in infectious diseases, acquired specific immunity, bacteriolysins and bactericidins, and the complement fixation reaction. The second part is concerned with practical immunization against tuberculosis, and contains chapters on specific prophylactic immunization against human tuberculosis, administration of the vaccine, practical results in prophylactic vaccination, and the specific treatment of pulmonary tuberculosis. The last part is concerned with experimental studies in the immunization against tuberculosis. The second part is that which will prove of greatest interest and value to the physician, and it should be read by all who are likely to combat the "great white plague."

Physiological Chemistry. A Textbook and Manual for Students. By Albert P. Mathews, Ph. D., Professor of Physiological Chemistry, University of Chicago. Second Edition. Illustrated. New York: William Wood & Co., 1916. Pp. xv-1040. (Price, $4.25.)

A lengthy review of the first edition of this book was presented to our readers as recently as February 19, 1916; so that it is unnecessary, on this occasion, to do more than call attention to the new edition of this capital work. Beyond the correction of a few mistakes, the addition of some references to papers which have appeared during the past year, and some trifling changes in the section on colloids, the book is the same as before. Physicians and students in search of a work on physiological chemistry will do well to examine the present volume; the facts presented are wisely selected and well arranged.

Manual of Chemistry. A Guide to Lectures and Laboratory Work for Beginners in Chemistry. A Textbook Specially Adapted for Students of Medicine, Pharmacy, and Dentistry. By W. Simon, Ph. D., M. D., Late Professor of Chemistry in the College of Physicians and Surgeons of Baltimore, and in the Baltimore College of Dental Surgery, and Daniel Base, Ph. D., Professor of Chemistry in the Maryland College of Pharmacy, Department of the University of Maryland, Baltimore. Eleventh Edition, Thoroughly Revised. With 55 Illustrations, One Colored Spectra Plate and Six Colored Plates Representing Forty-eight Chemical Reactions. Philadelphia and New York: Lea & Febiger, 1916. Pp. xvi-648.

That this book is now in its eleventh edition is sufficient proof that it is a work of considerable merit and that it has, also, supplied a want. In the present revision the pharmaceutical titles have been brought into agreement with the recent (and long delayed) Pharmacopœia; we also notice some material and a rearrangement of the sections dealing with inorganic chemistry. The most noticeable changes, however, are in the line of omission. The chapters on light and electricity have been banished from the work; so, too, has the whole of the section on physiological chemistry. It is true that the section on organic chemistry contains a chapter of a dozen pages dealing with the proteins, but this cannot be considered an adequate presentation of physiological chemistry. The result of these omissions is that a student will now require three books where formerly one sufficed. Since the first edition of this work appeared the chemistry required of the medical student has been greatly changed, both in extent and in character. He is now expected to acquire a much greater knowledge of the facts of chemistry, and, what is far more important, to obtain an adequate idea of the fundamental principles of the science. So, while the book is good, so far as it goes, it will hardly suffice the medical student beyond his first year; and, owing to the omission of physiological chemistry, it will be of very little service to the physician.

La Cure de soleil. Avec 40 figures, 107 planches en noir et 16 en couleurs. Paris: Baillière et fils; Lausanne; Constant Tarin, 1914. Pp. cxvii-217. (Price, 20 francs.)

In this imposing work are comprehensively set forth for the profession at large Rollier's experiences with sunlight therapeutics and the details of the application of this treatment in tuberculous lesions of various forms. The author immediately issues warning that in heliotherapy, if the best results are to be obtained, a very precise management of the treatment, with nothing left to chance, is necessary. He admits that in the striking results obtained by him at Leysin, Switzerland, not only sunlight but also altitude plays a part. Similar results may, however, it is stated, be obtained elsewhere at a suitable altitude. Prudent progression in the treatment and careful individual study for proper adjustment of the dose are essential to success. Eight or ten days are allowed new patients before sunlight treatment is begun, for acclimatization and to accustom the skin of the affected parts to the open air. Increasingly extensive portions of the body are then exposed to the sun for progressively augmenting periods. Meat is largely excluded from the diet and, as a rule, no attempt at hyperalimentation is made. To the skin surface is restored a long lost function, that of absorbing from the air and solar radiations hitherto overlooked forms of useful energy. Plaster apparatus, with its many disadvantages, is no longer used, and in Pott's disease the ventral posture, with the back exposed to the sun, is generally employed, with excellent effect. In joint tuberculosis, recovery of joint function is nearly always obtained. Among two thousand cases treated, in but one instance did a tuberculous focus lead to secondary infection. Reparative processes soon set in even in previously obstinate, atonic foci. Emaciated children with multiple sinuses, after some months' treatment and training, are so transformed and fortified that ice skating and other winter sports are indulged in without clothing. Numerous photographs have been inserted in the text, and the second half of the book is occupied wholly by illustrations showing the results of treatment in tuberculosis in various portions of the body. No one who studies this work can fail to be impressed with the solidity of the therapeutic principles enunciated. Sunlight therapeutics has manifestly come to stay, and applied under the conditions described by Rollier, yields results superior to any hitherto obtained. Great credit is due the author—a pupil of Kocher—for bringing, by dint of energy and perseverence, the heliotherapeutic method to so high a pinnacle of efficiency.

Interclinical Notes

The question of prohibition in the States is discussed editorially in the *Outlook* for November 15, 1916. The results of the recent election, it says, certainly ought to give comfort to the prohibitionists and the antisaloon group. As a wine hibber might put it, among other States Michigan went *sec*, while Detroit went positively *brut*. The extensive vineyards of California seem to complicate the problem in that beautiful, but not unco guid State.

* * *

In the Novemher *Century*, there are four camera studies by the late F. Benedict Herzog, extremely clever in their counterfeiting of painting. It is not art, however, to imitate another art. Pictures like these are good enough to stand on their own bottom. Another admirable camera portrait accompanies a tribute to the late Jean Webster, whose last serial in the *Century* we commented upon so freely and with such unrestrained enthusiasm. The young genius died in childbirth.

* * *

The New Public Health is an interesting subject interestingly discussed in the *Survey* for Novemher 18th, by Dr. Alice Hamilton and Gertrude Seymour. Among significant statements is one hy Doctor Rosenau, of Harvard-Technology, that a good class of students are willing to work long and hard to enter the new profession; many have accepted positions paying from $1,200 to $4,000 per annum. At Pennsylvania, too, it is said that the "pick" of the students are taking up puhlic health. Already twelve of the best medical schools give the requisite training; Columhia has a program ready.

* * *

It is a great pity that the soldiers of all the armies engaged in the present war are fond of cigarettes. If only their use had been confined to one army and that army had been defeated, what a beautiful object lesson! The wretched soldiers, however, seem to rank cigarettes along with sweaters, canned pâté, socks, candy, and the like; so we learn from *Leslie's* for November 2nd. With sumptuary legislation trembling in the balance concerning tobacco, alcohol, white slaves, narcotics, length of the working day, and wages, we are inclined at times to envy the fighting men in Europe, for if their discipline is strict, it is also wisely directed.

* * *

The *Survey* for November 18, 1916, is almost exclusively medical, discussing as it does College Men and Alcohol, the National Drug Problem, the New Public Health, and Birth Control. As to the first problem, it is now some years since we wrote our opinion that while alcohol and tobacco might, be allowed to tired men of middle age, it was a trifle absurd for a university undergraduate to advertise, by means of a gigantic pipe stuck between his teeth, that his shattered nervous system was in constant need of a narcotic. Do students still have individual mugs into which their heer must be drawn? Yea, there was such folly in the nineties.

Meetings of Local Medical Societies

Monday, *November 27th.*—Medical Society of the County of New York (annual); Poughkeepsie Academy of Medicine.

Tuesday, *November 28th.*—New York Academy of Medicine (Section in Obstetrics and Gynecology); New York Psychoanalytic Society; New York Dermatological Society; Metropolitan Medical Society of New York City; Buffalo Academy of Medicine (Section in Pathology); New York Medical Union; New York Otological Society (annual); New York City Riverside Practitioners' Society; Valentine Mott Medical Society, New York; Washington Heights Medical Society, New York (annual); Therapeutic Club.

Friday, *December 1st.*—New York Academy of Medicine; New Utrecht Medical Society; New York Microscopical Society; Gynecological Society, Brooklyn; Practitioners' Society of New York; Corning Medical Association; Alumni Association of Roosevelt Hospital.

Saturday, *December 2nd.*—Benjamin Rush Medical Society, New York.

Official News

United States Public Health Service:

Official list of changes in the stations and duties of commissioned and other officers of the United States Public Health Service for the seven days ending November 15, 1916:

Armstrong, Charles, Assistant Surgeon. Relieved at Ellis Island, N. Y.; will proceed to Arundel Cove, South Baltimore, Md., for duty on Coast Guard cutter *Itasca.*

Bahrenburg, L. P. H., Surgeon. Bureau letter dated November 4, 1916, directing him to proceed to Houston, Tex., cancelled.

Bryan, W. M., Passed Assistant Surgeon. Ordered to proceed to New Haven, Conn., to complete report on fatalities on steamer *Devonian.*

Faget, F. M., Assistant Surgeon. Ordered to proceed to New Haven, Conn., to complete report on fatalities on steamer *Devonian.*

Fox, Carroll, Surgeon. Ordered to proceed to South Bend, Ind., to study public health organization and administration.

Freeman, A. W., Epidemiologist. Ordered to proceed to New York city for conference on poliomyelitis.

Grubbs, W. B., Surgeon. Granted seven days' leave of absence from November 13, 1916, under paragraph 193, Service Regulations.

Guiteras, G. M., Surgeon. Directed to assume charge of Key West, Fla., Quarantine Station, during the absence of Acting Assistant Surgeon Light.

Harrington, F. D., Assistant Epidemiologist. Directed to proceed to Austin and other places in the State of Texas for conference relative to the most suitable county for studies of rural sanitation.

Holt, J. M., Surgeon. Directed to proceed to Toledo and Conneaut Harbor, Ohio, to inspect certain United States vessels.

Lloyd, B. J., Surgeon. Directed to proceed to Vancouver, B. C., to inquire into the practicability of an examination for cholera carriers under immigration law.

Oakley, J. H., Surgeon. Bureau letter dated November 1, 1916, granting four days' leave of absence from November 10, 1916, revoked.

Rhynus, C. P., Sanitary Engineer. Directed to proceed to the Great Lakes to observe operations of sewage steam disinfection on steamer *D. G. Kerr.*

Schereschewsky, J. W., Surgeon. Directed to proceed to Harrisburg, Pa., to attend the Fourth Annual Welfare and Efficiency Conference, November 21 to 23, 1916.

Sharp, W. K., Field Investigator. Directed to proceed to Berkeley County, W. Va., to make a resurvey of sanitary conditions.

Spencer, R. R., Assistant Surgeon. Granted seven days' additional leave of absence from November 13, 1916.

Stout, J. D., Assistant Surgeon. Relieved from duty on Coast Guard cutter *Itasca,* and will proceed to Norfolk, Va., for duty.

Tarbett, R. E., Sanitary Engineer. Directed to proceed to Spartanburg, S. C., to assist in the sanitary survey of cotton mill villages in connection with field studies of pellagra.

Thompson, W. R. P., Acting Assistant Surgeon. Granted two days' leave of absence from November 14, 1916.

Warren, B. S., Surgeon. Detailed to deliver an address on health insurance before the meeting of the Medical Society of the State of New York, at New York, N. Y., November 23, 1916.

Wheeler, G. A., Assistant Surgeon. Directed to proceed to Milledgeville, Ga., to observe dietary studies in relation to pellagra.

White, M. J., Surgeon. Directed to proceed to Topeka, Kan., to examine suspected case of typhus fever.

Births, Marriages, and Deaths

Married.

Bierer-Hankins.—In Uniontown, Pa., on Tuesday, October 31st, Dr. Charles D. Bierer and Miss Gertrude Hankins.

Collins-Lefferts.—In New York, N. Y., on Thursday, November 9th, Dr. Charles Farnham Collins and Mrs. Helena Gillet Lefferts.

West-Rusk.—In St. Louis, Mo., on Saturday, November 4th, Mr. William Miles West and Dr. Elizabeth Rusk.

Sandberg-Peterson.—In Chicago, Ill., on Saturday, November 4th, Dr. Karl F. M. Sandberg and Mrs. Emelia P. Peterson.

Died.

Beckman.—In Rochester, Minn., on Tuesday, November 7th, Dr. Emil H. Beckman, aged forty-five years.

Brown.—In Germantown, Ohio, on Thursday, November 9th, Dr. Joseph A. Brown, aged sixty-one years.

Burgess.—In Sumner, Tex., on Thursday, November 2nd, Dr. Neal L. Burgess, aged thirty-eight years.

Buttner.—In Orange, N. J., on Thursday, November 16th, Dr. Carl Buttner, aged sixty-seven years.

Culver.—In Harrisville, N. Y., on Sunday, October 29th, Dr. David J. Culver, aged sixty years.

Finder.—In Troy, N. Y., on Monday, November 20th, Dr. William Finder, Jr., aged sixty-one years.

Flanders.—In Pittsford, Vt., on Monday, November 13th, Dr. Charles A. Flanders, aged sixty-eight years.

Franklin.—In Philadelphia, Pa., on Monday, November 6th, Dr. Marcus M. Franklin, aged seventy-three years.

Garwood.—In North Lewisburg, Ohio, on Saturday, November 4th, Dr. James Stokes Garwood, aged sixty-nine years.

Holt.—In Parker, Pa., on Friday, November 10th, Dr. John Floyd Holt, of Pittsburgh, aged thirty-nine years.

Ledbetter.—In Shreveport, La., on Thursday, November 9th, Dr. Jesse M. Ledbetter, aged sixty-two years.

McMaster.—In New York, N. Y., on Wednesday, November 8th, Dr. Nathaniel G. McMaster, aged seventy-six years.

Ohlmacher.—In Detroit, Mich., on Thursday, November 9th, Dr. Albert Philip Ohlmacher, aged fifty-one years.

Parsons.—In Trenton, N. J., on Sunday, November 12th, Dr. Richard H. Parsons, aged fifty-seven years.

Russell.—In Birmingham, Ala., on Sunday, November 12th, Dr. Ralph M. Russell.

Spencer.—In Newark, N. Y., on Sunday, November 5th, Dr. Elwyn L. Spencer, aged fifty-nine years.

Spiron.—In Collinsville, Ill., on Saturday, November 4th, Dr. Peter D. Spiron, aged sixty years.

Tinker.—In Sharon, Pa., on Wednesday, November 8th, Dr. Guert M. Tinker, aged forty-seven years.

Townsend.—In Bennettsville, S. C., on Monday, November 13th, Dr. Arthur S. Townsend, aged fifty-three years.

Verdery.—In Fort Sam Houston, Tex., on Sunday, October 29th, Dr. Lee W. Verdery, aged twenty-eight years.

Way.—In Saranac Lake, N. Y., on Sunday, November 5th, Dr. A. Crandall Way, of Perry, N. Y., aged forty-six years.

PSORIASIS AS AN HYSTERICAL CONVERSION SYMBOLIZATION.

A Preliminary Report,

BY SMITH ELY JELLIFFE, M. D.,
New York;

AND ELIDA EVANS,
New York.

Paleontology is the study of past plant and animal life which has been preserved in the form of what are called fossils. Paleobotany and paleozoology are the respective titles given to the individual subdivisions of this branch of science.

Chiefly through evidence obtained in these fields, the scientific theory of evolution has become a useful working formula, the full significance of which has not by any means been grasped, nor have its implications been completely realized. The evolutionary attitude of mind has given birth to the idea of recapitulation, which emphasizes the fact that every living plant and animal, in its own growth, goes through the phases which characterize the ancestors in the direct phylum or branch. Just as there are many minor details in controversy relating to the central doctrine of evolution, so similar debatable points relative to the doctrine of recapitulation are under active discussion at the present time. With these we are not now concerned. We are interested only in an attempt to apply the principles in order to see if greater uniformity of interpretation may not result in fields where such uniformity is markedly lacking.

We wish to maintain the idea that there may be other types of fossils to be studied than those derived from plants and animals, namely, thought fossils, and that to paleobotany and to paleozoology we may add a science of paleopsychology. The happy hunting ground of the paleopsychologist is not, however, in the rocks and clays of old sea bottoms, but in history, in literature, in art, in customs, ceremonials, religions, institutions, and possibly diseases. Throughout all of these, evolutions from earlier, simpler to more complex types are recognizable. These customs, ceremonials, institutions, concepts, theories, diseases, etc., they too recapitulate the chief phases of earlier stages, and in order to understand them, as thought fossil recapitulations, special modes of study become needed, the general features of which are foreshadowed in the mode of approach to their more structural homologues.

One of the many principles which has brought about the development of the special changes in form is that of condensation. As the five toed eohippus of early Eocene days now walks as a stately horse upon one toe, so many concepts of former stages of civilization are condensed into a single formula, and thus function more advantageously than their many sided prototypes.

Few can estimate the greatly increased energy value of a new generalization, which, gathering up, condensing, as it were, the vast hordes of previous concepts, creates new intellectual tools of great constructive capacity. These new generalizations mark milestones in the progress of civilization. We may speak of them as inventions, such as the printing press, gunpowder, and aeroplanes; as laws, such as the Ten Commandments, the Twelve Tables, the Justinian Code, or the Code of Napoleon; as institutions, such as slavery, feudalism, socialism; as customs, which we term folkways, religions, etc. From the standpoint of the science of the evolution of thought, as interpreted through the concept of paleopsychology, all of these are capable of being interpreted in the light of their origins. In fact, unless they are genetically and dynamically so interpreted, other interpretations prove to be incomplete and faulty.

Other types of change by which the evolution of psychical structures may be measured are displacements, distortions, etc., all bringing about what we shall term in general *resymbolizations*. There is absolutely nothing new in this mode of looking at things. Back to the Greek is the present cry. Back to Heraclitus and to Protagoras we can go for a fairly good statement of this genetic dynamic unity, which present day psychiatry is insisting upon, in its endeavor to correlate psychical and physical phenomena, as seen in disease. But even if Heraclitus, with the flashlight of genius, irradiated the path from which man has so often diverged, he nevertheless has left us no clues as to practical every day appreciations in medicine, by which we may demonstrate the relationship between the patients' thought fossils and their mode of showing themselves in the body as symptoms. He gave us no practical rules for tracing out the evolutions of resymbolizations. Such a modern Heraclitus is Freud, and by means of the direct practical technic

of psychanalysis, the student of medicine is in a position to understand a host of disease phenomena which, up to the present time, were in a chaotic state of misinterpretation.

The present paper will confine itself to a study of some resymbolizations as showing themselves in the skin area, and as classed under various symbols which dermatologists treat of as diseases, because of their different clinical course or morphological characteristics.

Dermatologists themselves, possibly more than any other group of specialists, complain of the chaotic state of their science. We read this in the preface of practically every standard work on dermatology published within the past twenty-five years. It is not the purpose of this paper to endeavor in any way to correct this, but it has for one of its purposes the wish to widen some present day dermatological conceptions.

Current etiological factors, such as inflammation, heredity, toxic, neuropathic, and other designations are a collection of meaningless truisms. They have little that is really dynamic or interpretative behind them.

There are good and sufficient reasons why the interpretating of skin disorders, particularly, should suffer from a paucity of dynamic concepts, but this is not the place to discuss them. This presentation deals solely with emphasizing the fact that, here in dermatology, as is true for all other disorders of the body, no real dynamic and genetic disease concept is adequate if it neglects the massive truth that the most important and undeniable fact of human existence is man's psychical inheritance. Without a study of man's thought fossils as intimately related to the health of every structure of the human body, no human pathology is complete.

What we, as physicians, have been satisfied to call pathology may be and has been practically expedient, but it is far from being a satisfactory pathology. Psychical factors, it is true, have less and less genetic significance as we move from the purely psychogenic disorders, such as hysteria, compulsion neurosis, etc., to such purely physical ills as hemorrhage from a bullet wound, or the burning of the skin by means of a fire, or rhus toxicodendron poisoning, but, nevertheless, such psychical factors, if present, should be understood in terms of energy.

So far as the skin is concerned, the present paper limits itself to an intensive study of a particular case. It is one chosen from a host of skin anomalies and disorders which have been seen by dermatologists and treated to no avail. The failure to modify the skin condition in these cases has been due largely to a fundamental failure to take into consideration factors of dynamic import, resident in the psyche of the individuals in question. These factors have been handled by the patients unconsciously through skin symbolisms. These skin symbols are the thought fossils of the individuals under consideration. The particular case we shall report is one in which the skin symbol has been termed psoriasis by dermatologists.

In the first place, it should be specifically emphasized that there is here not the least scintilla of a claim to state what psoriasis is, neither is there an attempt made to allege psoriasis to be always an hysterical conversion syndrome, but it is most emphatically held that this particular psoriatic affection in this patient is chiefly psychogenic in origin.

The analysis of patients with psoriasis who have come for other ailments may tempt us to make an inference that a large number of psoriasis lesions are undoubtedly psychogenic in origin. This larger phase of the subject will be discussed separately. The present case represents an attempt to understand the dynamics of the skin reactions in terms of the hidden psychological factors of the individual life, the patient's thought fossils, to wit, the more primitive and earlier (phylogenetically speaking) ways of accomplishing life's destiny. No amount of working on the outside of this patient's body is likely to change her mode of expression of this life desire. A reconstruction of her attitude toward life and its realities must be gained, or she will bear the marks of her failure to live up to life's opportunities.

Case. Young woman, of twenty-six years, American born, of Austrian Jewish parentage. Her father died in 1909, of an "intestinal obstruction." The patient lived with her mother and an older sister and younger brother, both unmarried. A married brother lived a short distance away. All were healthy except the younger brother, who had a tendency to tuberculosis. The patient as a child had measles and whooping cough, otherwise was healthy. She had had no adult disease nor operation.[1]

The complaint of the patient did not begin with psoriasis, but with a pain in the back of the head, and the findings in the study of the case pointed to the fact, that psoriasis was not a thing to be treated by itself, but a symptom of a hysterical conversion, whereby the patient sought relief and an outlet for the libido with infantile desires. In the history of this patient, for a few years previous to her analysis (to be given in more detail later on), it was important to see how she had gone from one physician to another, and how all treatments advised would succeed for a while, then the complaint would suddenly become active again without apparent cause. The most careful physical examination failed to reveal organic trouble or disturbance in the daily functioning. The patient slept well, with good digestion, and no decrease of efficiency in her daily work in an office downtown.

From earliest childhood she had craved love and care in the form of some physical attention. At three years of age, her mother occasionally combed her hair a long time for purposes of cleanliness, dandruff, etc., which always gave the patient the greatest satisfaction; in her words, she just "loved it," but the mother seldom had time for a quiet hour to give to the little daughter's hair; she was very unhappy when left to herself and constantly demanded attention. The father and little brother, she said, understood her better, and tears flowed freely when she told of her family's indifference to her troubles. "They do not seem to care, neither my mother nor my sister," she exclaimed angrily and bitterly. Previous to her father's death, in 1909, during her twenty-first year, she had developed along the usual lines of jealousies and affections of a girl who forms one of a large family. She had passed through a high school with credit, and worked as a commercial stenographer for three years in the office of an importing house.

A few months after the father's death, she began a restless wandering from one physician to another, complaining of a pain in the head in the occipital region, and finally was advised to consult me, through Doctor Casamajor of this city. After working with her a few weeks, she was provisionally classified as belonging to a group of patients for whom psychanalysis was not impossible, but from whom we could expect little by its application

[1] We call this a preliminary report as the case was not begun until May, when only six weeks could be given to the analysis, but it is impossible, in these few pages, to present the mass of detail which accumulated in that short time. The literature bearing on psychanalytic studies of psoriasis are very meagre. I shall consider them in a later paper. Owing to limitations of space, there are many dreams and associations which cannot be given.

except through great rearrangement of her character trends. Such a patient was generally not cured by psychanalytic methods. Some help might be derived, but in fact such patients did not want to get well. They received a certain satisfaction from their complaint and used it for an excuse for continuing the neurosis. These patients have been called "The little bird group." Jelliffe (*Psychoanalytic Review*, II, 1) says:

"It is highly important to recognize this group with the subgroups, for there are many individuals in them, and as it is the habit of such individuals to go from doctor to doctor, they are the chief factors in carrying gossip, and in giving usually very tenuous basis for the misinterpretations which result, not directed to psychanalysis alone, but in all branches of medicine. I call them the 'little bird group.' They are all types of personalities, but most of them have little interest in anything, are somewhat introverted, but are capable of establishing a superficial rapport with great ease, and fall away quickly to seek a new attachment. One cannot escape them. Whether one treats them or not, they will say things to the next claimant for their favor which conscious, as well as unconscious, rivalry seizes upon to augment bad feeling among us. They are not infrequently superficially clever. There is an active and a passive subgroup. The women are chiefly in the former, the men in the latter. The former are more malicious in their comments on the other doctors. Many of these patients do not care to get well. They use their neurosis to keep up a type of 'peeping.' They will not see themselves, and have little courage to do any real work. When once embarked on an analytic treatment with these patients, they hang on and on, so long as their small vanities and foibles are undisturbed. When the analytic probe bears heavily on these, they pout and fall away. A strong insistence upon having 'backbone' and 'standing up to their task' causes a further flight, this time to the gastroenterologist, or the gynecologist, or what not, and the analyst wakes up to find that his work has only contributed to the fantasies, usually of an autoerotic 'infantile or adolescent type.'"

Jelliffe accordingly advised this patient to consult one of his assistants, as the superficial rapport, easily established, gave unconscious evidence of a new attachment whereby the hysterical symptoms could serve as a direct unconscious sexual gratification in the restricted sense, so that a very strong transference would result in new symptoms of the neurosis. He therefore telephoned to his assistant that he was sending a case of psoriasis for analytic study. Two weeks passed before the patient, Miss K., called her up. She then assumed an attitude of surprise and wonder, did not understand why Doctor X. should want her analyzed, did not see why he asked her to come to his assistant, did not know what he wanted, etc. It thus became evident that her resistance was not only to analysis, but to coming to a woman for analysis. Doctor Jelliffe's assistant suggested her coming on the following day for a call so that she might have the pleasure of meeting a patient in whom Doctor X. was so much interested. I now give the patient's history in the terms of my assistant, Mrs. Evans, to whom Doctor Jelliffe is indebted for parts of this record. "'Do you think he is interested in me? He does not act as though he were.' I assured her Doctor X. was very much interested, and with the promise of learning more about Doctor X.'s interest concerning her, she agreed to come on the following day, at six o'clock.

"The patient came as appointed and proved to be a tall, athletic looking young woman, with the manners of a school girl; she had books under her arm. Her hair, of light chestnut color, was wiry and crinkly, like mulatto hair. It was worn as a low pompadour, coming well down over the forehead and coiled in a loose knot at the back, low in the neck, which concealed the spots of psoriasis of the skin, on the edges of the scalp, on the forehead, and nape of the neck. She began by repeating her remarks made over the telephone, that she did not understand what Doctor X. wanted, why he asked her to see me, etc. When told it was probably because Doctor X. was interested in her and wanted her to recover her health, she declared she was well. When asked why she went to Doctor X. if she were well, the resistances were broken for a time. There were floods of tears. The question had touched a complex, a sore spot which hurt. I questioned further, if she were well, why should she seek medical advice. She began protesting very emphatically, that she was not a psoriatic, that she did not have 'regular' psoriasis, that she had no time for analysis, she was very busy with her studies, preparing to go to a western university in the fall to 'take up' her studies. Tears flowed constantly during the entire hour, but there was no sobbing, no convulsive movement of the face as in the efforts for relief in hysteria; she acted like a child with wounded feelings. It was difficult to obtain much clinical history, she changed nervously in conversation from one subject to another, saying she knew what was the matter with her and what she wanted. She evidently had learned, in her previous analysis of some of her complexes, but had concluded in her own mind they would be cured by marriage, at the same time refusing to see that those complexes prevented her marriage, as she did not attempt to attract by development of character and personality, but used her psoriasis as a means of obtaining the attention and interest of physicians, who represented to her the father. She said that she had to get away from her family, she could not live with them, and that she was going west in the fall. When asked why she used the words, 'take up' rather than the word 'study,' a fresh flow of tears came as she declared it meant the same thing, but as may be seen by her later confession how important the choice of words used by a patient may be in determining the latent meaning. In looking over the appointment book to see which hour could be given on the following day, she begged to be allowed to come in the evening, in order to get away from her family. She finally concluded to come at five o'clock, and asked that that hour be kept for her future visits.

"She came promptly the next day and stayed two hours, talking constantly, telling of her troubles at home, where no one understood her and no one cared about her psoriasis, which she said had also appeared in the pubic hair and was followed by boils. She had had them cared for by a young physician in the Y. hospital. More tears with the description of visiting the young physician, but no mention of any pain or inconvenience with the boils. She talked much of her married brother, whose wife had a month old baby, and attempted to tell of her sister's visit there, when the brother was found 'diapering' the baby. At each attempt, as she approached the climax of her story, where the sister opened the door and saw the brother arranging and folding a diaper while the baby lay exposed and crying, the patient became excited, and violently protested that her sister-in-law, the baby's mother, was not all that her brother's wife ought to be. Eight times in an hour the patient repeated the sentence: 'And as A. opened the door to go in, there was B. diapering the baby.' When asked why she repeated that eight times, she did not know she had done so, was surprised and incredulous.

"The patient described the psoriasis which existed on the scalp and in the pubic hair. Her mother told her she had had dandruff when a child of three years, and how she used to comb her hair. The patient remembered that she always felt good after she had had her hair combed and scalp rubbed, and did now, when her mother attended to her. 'I feel like a queen when I have had my hair fixed.' Tears started again when telling of her mother's indifference.

"On the next visit she brought a dream, which is given in full as the first dream not infrequently contains the chief problem causing the neurosis:[2]

"'Went to a man to ask his advice about some poetry. He said it was fine poetry and quoted a little of it. Then I left him and walked down a street. When I turned around he was considerably behind me. He had light eyes (not the very light, insipid kind) and rather olive skin. He was very big and very fat, with a great big corporation, and he had an overcoat and large Fedora hat. He looked at me rather intensely, more interested than flirty. Saw a body of water and a continuous fence, very high, like a wall. I was holding on to the fence. At one time I thought I had to hold on and slide along because there was no room to walk, also at one time I thought my feet were off the ground, I was all up in the air. I saw some docks.'"

"The analysis of the dream was slow and difficult. Her mind wandered from associations to conversation. Association of asking the man about some poetry was the doctor to whom she had been to ask about the boils she had on

[2]Jelliffe: Technique of Psychoanalysis. *Psychoanalytic Review*, I, ii, iii.

the vulva, a young doctor in the Y hospital. He had operated on the boils and said the case was interesting—*'said poetry was fine and quoted some of it.'* The doctor said something to her, she said, and she wished she had answered him differently (a pleased smile spread over her face); the next time she went to the hospital, he would not look at her boils (tears), he hardly looked at her, said he was too busy and left her (by projection in the dream she left him and walked down a street, leaving him behind). In the dream she described a composite man, several of the physicians she had been to, Doctor X., and a Doctor M., who, she averred, had pinched her cheeks on several occasions, and had kissed her once—with mysterious references to something not done. Then suddenly with a burst of tears came a remembrance, and she exclaimed angrily, 'Once I went to Doctor M. and he would not look at my boils either, just gave me something; I know why he would not look,' and she hinted that M. was a weak man, although he had a 'good, strong nose, such as my father had.'"

The composite man, in the dream, made of several physicians, wore an overcoat and a large tan Fedora hat. As is known, the latent content of the dream differs greatly from the manifest, where one must dig deep to find the symbolism. The resistance of the patient prevented direct associations for the overcoat and tan Fedora hat. The teleological meaning of the dream is apparent to any psychanalyst, and further on, the dreams will show plainly why the censor of the unconscious used a tan Fedora hat with its color corresponding to the patient's hair, its surface soft and fuzzy, its shape of an indentation between mounds to express the object, which covered the head of the man wearing an overcoat; the association of "overcoat" was "protection from rain or wet," and the symbolism of coitus appears with the polyandrous desires of the patient which frequently recurred during the analysis. The man *"looked intensely, more interested than flirty,"* she has already compared him to her father in the resemblance of the nose, and so she seeks the father in man. There is the father love and protection in the man who looks at her "more interested than flirty."

There now follows "a body of water and a continuous fence, very high, like a wall. I was holding on to the fence. At one time I thought I had to hold on and slide along it because there was no room to walk; also at one time I thought my feet were off the ground. I was all up in the air. I think I saw docks."

Water, containing the invisible life swimming in its liquid element, is a frequent symbolism of the liquid containing the seed of human life; this body of water (the father element) is separated in the dream, from the earth (the mother element) by a high fence or wall which the patient has built of resistances to efforts, necessary for self control and adjustment to life, which would destroy the wall, thus enabling the patient to marry, and the mother earth would absorb the life-giving water. The unconscious of the patient portrayed that she was clinging to this wall of infantile desires, built by resistances to adult life with its responsibilities and demands for self control, in order that she might remain in the period of childhood and adolescence. She had to *"hold on and slide along because there was no room to walk."* She cannot live at home with her family because they will not indulge and sympathize. There is no ground to her reasons—*"my feet were off the ground, I was all up in the air,"* and she is indeed "all up in the air." Spell the word "docks," "Doc" slang for doctor, and a clear view of the cause of the neurosis may be revealed. Throughout the hour the patient constantly interrupted the analysis to tell of her success in attracting the various physicians she had called on to examine her psoriasis.

At the third interview, the patient brought several dreams; the first one was:

"Bouquet of flowers in the parlor. 'Why, in her married sister's house?' I thought in the dream. Oh! she lives with her married sister. She can go up (in the parlor) and look at the flowers every night. I am associating some one else's parlor with these flowers."

It is an illustration of the thought quoted, showing the establishment of a superficial rapport with great ease. The patient has no married sister. Her analyst is a married woman, a piano is in her office and flowers. The association with flowers was, "Faces sometimes look like flowers; once I had a teacher whose face was like a flower when she smiled."

The second part of the dream is: "Fair, fat, unshapely girl ran past us with two beautiful hairy dogs. Both were large and well developed, but quite a difference in size, due to difference in breed. I was sitting with mother and brother some place in the open. Called brother's attention to the dogs, but he missed them, they were running very fast. Then they turned around and came to us. She was hot and out of breath. She threw a gold medal against the fence for some one, in the hope it would stay up there. It didn't, it fell down. She was looking for some one to give it to and couldn't find him. I said, 'Is he a graduate of Columbia? If he is, you can leave it for him with some one on the grounds.' She said, 'No, Brown's.'"

There is too much material in this dream to crowd into a small space. We see again the symbolism of the hair, covering "two beautiful hairy dogs." When asked for associations, she said none came, then after a moment's pause, began telling how she had told Dr. X., her former analyst, all about Dr. M.; and when she asked his (Dr. M.'s) advice about boils on the vulva he would not look at them, but prescribed for them (which she described on second interview), so again in third interview the patient is "running hot and out of breath" with two dogs of different breed (German and American) covered with hair. She was out in the open, showing exhibitionistic desires. The climax of the running was shown when the dogs turned around and "came to us," she was hot and out of breath (orgasm). The gold medal brought associations of the scholarship which she had been working for in Y university, as she had no means with which to take up her further studies. In the dream the medal fell down (she failed to win the scholarship) and she looked for some one to give herself to. "Will it be a graduate of Columbia" to be attracted by her mental efforts? "No, Brown's." The association of Brown brought the color and not the university of that name, and showed a play upon words, which often occurs in the dream and waking hours,[3] very valuable in psychanalysis. In this instance, it shows the presence of fecal fantasies so frequently found in the patient seeking satisfaction in the infantile fantasy life. In other words, she will not give herself to one who is attracted by her finer efforts in intellectual work or to scholarship, but to one who is attracted by her childish fantasies (that is, her sexuality), and, unable to find him, she

[3] Freud: *Psychopathology*, etc.

gives herself to her brother, as shown in the third part of her dream, as follows:

"In the distance there was a large hammock. It did not look like one; it was very elevated, so high that I could not get in it. I looked around for a ladder, but there was none. I could see it was made from white canvas and light brown wood. Neither did it look as though it could be swung. Brother picked up the fallen medal. Hammock was very large, and I thought, 'How many will be able to get into it?' It had no shade and I thought how terrible it would be if the sun was strong."

The associations of "hammock" led to the menstrual napkin—to her own sex which was calling, but the demands it made were so high she could not reach them. She had surrounded herself by a high wall of resistances, as had been seen in the first dream, and in trying to overcome them by her scholarship, she failed, and fell down to her family. "There is no ladder." Her brother picked up the fallen medal. The associations with her brother touched another sore spot, and there was a flood of tears while she told of the deep understanding between herself and younger, unmarried brother. They always exchanged glances when anything was said by other members of the family. The patient constantly interrupted her associations to tell how she had attracted some man whom she had met, or knew only slightly. The one absorbing topic was her desire to attract men. The exhibitionist desires were shown again, "the hammock had no shade." She thought how terrible it would be if the sun (son) were strong, like her father. When asked why she added the words, like her father, when she had spelled the word, *s u n*, and why terrible, if the sun was strong, she said she did not know, and began talking of her psoriasis, the boils on the vulva, and then changed to her married brother, and his care for the baby.

The symbolism of the sun as the strongest creative power, needs no explanation. The other parts of the dream, which are too long to give in full, were of exhibitionism, carrying clothes on her arm, and seeking to attract the men she formerly had worked for, as stenographer.

During the third and fourth interviews, the dreams showed sexual desires of the patient: "Heavy upholstered sofa; saw Doctor B. very distinctly. He was in very high spirits and very playful; at the same time he was serious, forceful, and resistant. I had all I could do to resist. I was more insistent than he; so he did not have his way (he used to say he would never do anything against my will). I do not recall the position, but I think I felt strong hands around my arms, trying to hold me down."

There is not much veiled symbolism here, but there is hysterical contradiction in her language. In the other dreams she was with a man with light brown hair, the color of her hair, who wore a tan spring overcoat, as in a former dream.

Her exhibitionist desires now extend to the woman analyst, my assistant. "All day yesterday I thought my teacher, Miss Short, would examine her class, and last night I dreamed she was really going to do so. I was not prepared and foolishly ran downstairs to study" (going down in her memory to study herself is foolish).

The patient was very contradictory, saying she heard all that was said to her, but did not believe any of it. When told the dreams were her own unconscious thoughts showing her real desires, she declared she knew her desires and when she married they would be gratified. She complained very much of her scalp condition, and said the psoriasis was very bad. No one at home cared anything about it. She thought boils were again on the vulva, she lifted the hair from the forehead to show the bright red spots of psoriasis on the edge of the forehead, also on the nape of the neck. In her dream the analyst had ignored the desire to examine the psoriasis in the pubic hair, and attention was riveted on the next dream to see if it would express her disappointment. This she did, as shown in the fourth part of her dream, of the sixth interview.

On the sixth interview she brought dreams in five parts. The first part was as follows: "Saw a boy and girl I knew (brother and sister) married, and living in the country. I was with them in a barn. He was working, perched on some elevation. When he saw me he said, 'Hello' (calling patient by her name), jumped down, passed me, and went in a room where he intended to undress."

The analysis showed the patient was married and living with her brother in a country barn (with uncontrolled animal desires). In second part of dream, she is being received by a professor, who had a "good, strong nose" like her father, in his private office. Third part of dream showed childish fantasies. Fourth part of dream showed her resentment of analyst not examining pubic hair for the possible beginning of boils at previous interview: "In a room with Miss Short and girls of zoology class, door with two curtains pushed aside. Miss Short had her blue suit on and did not look as pretty as usual, ears seemed very small, neck was full of powder, even under the powder her skin seemed dark. She asked a question in mathematics, the three parts of a proposition or theorem, and embarrassed one of the girls who couldn't answer."

As the analyst did not use powder, it was evident the patient was thinking she did not want analysis with a woman who said embarrassing things to her. Fifth part of dream: "Mr. L. was seated at his desk. He was looking at a feather that had two parts, so that it could be worn on the upper and under side of a hat. He had two stenographers. I was one, but the feather—the nicest of two gifts—was not intended for me. As he was seated at his desk, looking at the feather, the other girl came over to me with, I think, a string of beads. I was not satisfied and didn't like them."

This dream was very important. It showed again the infantile desire of the exhibitionist, to attract attention and receive sexual gratification by means of the psoriasis. The analysis of this fifth part of her dream was: She thinks of her analysis with Doctor X., sitting at his desk, looking at her hair (upper and under side), the head and pubic hair. He would not indulge her fantasies, but sent her for analysis to his assistant, a woman, from whom she received the string of beads or something like beads. The associations of feathers and beads lead from Indians and primitive people to the Druids and mistletoe, the berries of which resemble drops of seminal fluid. In our customs the first kiss given beneath the mistletoe is symbolic of marriage, and receiving later the new life, from the life-giving fluid. The patient was not satisfied with analysis by a woman, and receiving new life from her.

As the patient was always admiring strength, there was probably some masochistic tendency. Different technic was required, stronger language, and treatment rather than the more gentle methods. She had admired the doctor who was "forceful and insistent," henceforth her analysis must be so, even though it hurt. The patient had been quiet and not interested throughout the hour, said she did not believe she would get any help from analysis, did not know whether she would continue. She only smiled and looked pleased when talking of men, saying she could attract them. She said she was going to hunt up a new doctor she had heard of, one who had a secret way of treating psoriasis and she was going to see him, perhaps tomorrow. With a quick jerking up of the reins, she was forbidden to see any

physician for her psoriasis, and told, in very forcible language, what a disgusting exhibition she made of herself when asking doctors to examine the vulva for boils. She was reminded that the genitals were never beautiful and when diseased they were loathsome. How could a mind filled with fecal fantasies and anal eroticism (shown by the "gold medal" and many other symbols) create a fine personality? She must overcome the infantile fixation of the libido on herself, she must firmly stand and face herself, and look directly into the depths of her reasons for going from one doctor to another, trying to arouse the father in every physician by asking for his care, protection, and interest in herself; but also seeking the virile man. To seek both the father, or brother, and lover in one man was incestuous.

The outburst of strong words on the patient did not hurt, but, on the contrary, resulted in a child-like submissive attitude of the patient, who promised to obey implicitly and not go again to a physician during her analysis, no matter how strong her temptations to do so. It was necessary to make her feel within herself, that it was impossible to see a physician for a month in order to watch the effect on the psoriasis. The firmer grasp of the analysis broke her resistance for a while.

She talked of her troubles at home and her envious feelings as she watched her sister, when reading, let down her hair and sit for hours running her fingers through her hair, gently rubbing the scalp. And then again, how her sister holds her head under the warm water faucet while the water trickles over it. The patient tearfully declared how she would like to do the same, and how she almost hated her sister. It was pointed out to the patient that this was an unconscious masturbatory practice, and that the most primitive people known have discovered the ill effects resulting from the frequent use of the erogenous zones of childhood, in rubbing their scalps after puberty, at which time they undergo certain rites of initiation, lasting from two to three months; and then they are forbidden to scratch the skin or scalp with their hands.[4]

On the next visit she brought no dream, and again was indifferent to analysis. The former dream of marriage to her brother was reviewed. The Electra and Œdipus complexes were then discussed. The Greek play of Œdipus was at that time on the stage of a New York theatre, vividly portrayed, and one felt intensely the terrible mental anguish of Œdipus, when he discovered he had married his mother, the incest horror of which drove him to stab out his eyes that he might not see the results of incest in his two daughters, by his mother; also the mother's suicide, after the terrible realization of the sickening incest with her son and their two children. And again the patient's resistances broke down. Unwilling to face herself, with her libido fast to father and brother, she runs from man to man, looking not for *the man*, but for *the father*. The men of her dreams are married men. Unable to attract them with her fine physique and mental attainments and personality, she finds a sympathetic attitude comes from physicians when showing them her psoriasis; thus has arisen the fascination of the visits to physicians. In fact, she not only finds a fascination in those visits, but it is the nearest approach she can find to the satisfaction she craves for the instincts of her strong psychic makeup.

On the next visit she brought several dreams: She was on an open car and saw a man carrying a cane. She was embracing a man very tightly around the neck, to whisper something in his ear—a sort of confession. Then she was in a large kitchen where there were two classes of people, the maids and a better class; the maids were throwing away frankfurters and creamed potatoes, which she could not understand, as they looked very appetizing; the patient was in her nightdress, the kitchen seemed to be in Eighty-eighth Street; they all felt embarrassed because her sister went to the sink to get something, or for something.

In the analysis of those dreams the man carrying a cane was her father, who carried a cane; once he hit her with it. Embracing a man and whispering to a man, brought associations of going to a doctor and asking him to look and see if she was not carrying psoriasis in her ear, and he refused to treat her ear unless he could also treat her scalp; that, she refused, saying only Doctor M. could do that; associations of kitchen, cooking, preparation for the satisfaction of desires and needs of the inner self; the lower nature was the maids who live by attending to the wants of the animal nature: frankfurters a fecal fantasy; creamed potatoes led to associations of the potatoes resembling the testicle, and the creamed potato, the seminal fluid; the sink, a urinal. The patient constantly interrupted the analysis by speaking of a man she had met and saying, "I think there was some attraction there." It was necessary to remind her of her exhibitionist desires, by always insisting upon the examination of her psoriasis when she would not use the remedies prescribed, only those of Doctor M., who she declared was attracted by her and attempted familiarities. She was told of the childishness of wishing to show her body, which did not interest, but, as she had seen with Doctor M., and the young physician at the hospital, produced disgust.

On the following visit there was no dream. The hour was passed in explaining the regression of the libido which she must endeavor to bring up again, to overcome the degradation of the infantile fantasies. The libido, like all of nature's forces, must be under one's control or it becomes one's master, driving the individual along the line of least control, and destroys. A week had passed since the patient had been forbidden to visit a physician for her psoriasis, and it was interesting to see that the bright red color of the spots had changed to a dull pink.

The analysis of the dreams of the next visit showed the patient seeking sexual satisfaction and the father. She saw her wall of resistance, but would not stop to think about them ("was in Wall Street, but was in a hurry"). The father (Mr. K., her father's friend) is willing to give her the satisfaction she seeks, but she remembers that Mr. K. killed himself, which is the dream by projection—the father must be killed, for if he helps her, it will kill her. In another dream, which the patient had written out and handed me, saying, "Here is another hair dream," she sits in the front row of a class (exhibitionist). Each of the class were given a piece of paper and told how to use it. She did not obey and wanted another piece, but could not get it. The teacher said '8 off'; the figure 8 brought associations of the buttocks, showing another fecal fantasy, using toilette paper. In the latter part of the dream was "a dirty hat with feathers on it. I put it on my head, then, under the desk. Doctor X., in the 'middle of the whole thing,' put it on. It was shapeless and dirty; then he started to eat an apple, this, while he was writing on the

[4] Spencer and Gillen: *Northern Tribes of Central Australia.*

board." Associations of "dirty hat" was the patient's hair, which needed cleaning and brushing; eating an apple led to associations of the Biblical narrative, thus it may be seen that she wished to have Doctor X. put on her hair (coitus) before eating of the fruit of knowledge (her analysis), while he wrote down her dreams and their associations.

The next visit brought a dream of: "A number of hats, among them I saw a hat with a white satin band and bow." Going over the associations of hat brought, "covering, something I need very much, a sore spot with me (the need of a hat), associations of white satin—bridal; white satin which she had taken from the lining of a coat her father had given her; the coat was red, with skirt of same material and color. She had been very fond of the suit."

Pointed out to the patient was the close relationship between her association of hat as a sore spot with her, and her psoriasis, and the bridal association with her father. She talked more of her home life, how she likes always to have her clothes in sight, so that she remembers she has them to wear. She likes to have them lying on the piano and on the chairs. If her clothes were put away she would go on wearing the same ones forever. Her clothes, lying around on the piano and chairs, are closely connected with her exhibitionist desires and are infantile.

The psoriasis is now very dim, could not be seen in the patient's hair.

The next dream of the following visit was: "I saw a girl, about thirteen or fourteen years old. She wore a bright red ribbon in the hair, or I suggested her getting one, and she wore a bright red plaited skirt, short."

The patient said she had had another hair dream, and declared she was very fond of a red dress, but that no decent man would wear a red tie. Asked what was indecent about red, she did not know, but to her red meant danger and excitement. It was pointed out to her that excitement caused the red spots of psoriasis. The analysis of her dream showed further desire of the exhibitionist in the red in her hair and around the body. The patient told of her psoriatic condition being much better, and showed the spots without color. For the first time, she talked freely of her resistance to analysis, because she did not want to work within herself, to get over her wall where she would have to face the world, but hid behind this wall, away from people, to stay and indulge all her infantile fantasies. She said she knew there was something wrong with her, because she had wasted all day Saturday; she had seen a man with her father's figure, who was in the department of ——— in the university. She could not get him out of her mind, pictured herself married to this man. She said, further, she had plenty of time for her analysis, but was always unwilling to write down her dreams, and did not want them analyzed because she did not want to work and overcome her troubles at home, by seeing within herself that she herself was the cause of them; she had no sense of responsibility, she wanted to get away from her family, and hoped when she went west to college she would marry before her first year was up, and then she thought her neurosis would be cured. It was explained to her that her complexes were those which prevented a happy married life. The Œdipus complex, with the libido fast to the father, made it impossible to give real love to any man; it made prostitutes, but not real wives and mothers.

In the next dream, "the doctors were doing something to her knee, putting something in or taking something out," she said. Associations, knee cap, water on the knee, under the knee cap. Pointed out that dream was again of something to cover the head—water on the knee under the knee-cap was sexual association with doctors. The dream on the next visit was: "My sister and brother were fighting violently. Sister was furious, especially when she saw that her hand was bleeding. She had on her glove, but the blood came through. Then she walked over to her brother and hit him on the back with a strap. He cried aloud and writhed with pain. What surprised me so was that mother was so passive about the whole thing."

Here occurs the very first dream in which the patient is fighting to kill her complex, but even then she cannot face it, but hits from the back. She has at last overcome some of her resistances, and sees how her complexes have taken away her power, disabled her with her right hand bleeding. But the strength of climbing over her wall of resistance had not come from her; the analysis had held her in forbidding visits to physicians. While leaning on another's strength (the mother, her analysis) she had faced her complex and saw her wounded hand; what she had clung to, or held for support, had hurt her. She talked much of her hatred and jealousy of her sister, said that was what kept her psoriasis active, and kept her in a constant nervous condition. She thought her mother cared more for her sister than for her.

The next three appointments the patient did not keep, but telephoned that she was taking her examinations at the university. This date brought her analysis to a partial close. She came to say goodbye, and wept nearly all the time. When she had been forbidden going to a physician two weeks previously, she had disobeyed and taken her mother to a physician for treatment for constipation, much to the disgust of the old lady, who refused; the patient persisted; the mother went once and would not go again. "She did not appreciate it one bit," wept the patient, who could not understand why the mother did not consider a visit to a physician with the same satisfaction as the patient did. Oil enemas were prescribed for the mother; she refused to use them; the patient attempted to give them to her mother, but had to give it up. The patient again said that in going to a medical college she hoped some one would marry her before she got as far as surgery. Wasn't even sure she could go into the dissecting room; sure she would faint away. Admitted she did not care anything about the study of medicine, but wanted to get away from her family. We explained that was probably true, but it was also true that she was taking the surest way of keeping herself surrounded with doctors. The psoriasis was still quiet, no color nor scales being present.

We have fortunately been given the clinical history, taken by the first physician she applied to after her father's death, and the histories of several other physicians, and skin specialists. The first history taken gives the physical condition good, appetite good, sleeps well, bowels regular; the complaint is a "pain in the back of the head." The same history reads: "The patient, in June, 1910, struck her head against a bedpost in her sleep, getting a slight bruise, was not inconvenienced by it and her head (occiput) pained only 'as a bruise would.' Later, the pain became worse and was constant." The history goes on to state that the physician gave her some ointment and suggested that she see a nerve specialist. This she did not do, as she said the ointment helped her and the pain gradually subsided after two months. "She was well until three weeks ago, when it returned with increased severity, getting rapidly worse. She stated that she has 'been incapacitated for the past two weeks,' but in spite of this, she has not missed one day of her work. She had been studying at night to enter college, but now feels unable to do her studying. She works all day, with no decrease of efficiency. Her hair is coarse and rather dry. Skin, however, feels normal and there are no other signs of dysthyroidism." This is the first mention of her hair, but there is no psoriasis yet. Notice the hysterical contradiction,

that she has been incapacitated for the past two weeks, and at the same time, she says she works with no decrease of efficiency.

We begin to see, here, the regression of the libido from her work and environment, and later the lost libido strives to effect a transference to the young, unmarried brother. He, however, does not prove a sufficient outlet, perhaps from his own efforts to free himself from the family. He loses his health and has a severe illness in a hospital; she has no one to depend upon and reverts to the past, where the father was the ideal, and finally constructs a sexual exhibitionistic substitute—a resymbolization in the form of red spots on the skin—psoriasis.

64 West Fifty-sixth Street.

FOCAL MOUTH INFECTIONS, THEIR SYSTEMIC EFFECTS, AND TREATMENT.*

By Robert H. Babcock, M. D.,
Chicago.

It is not intended in this paper to deal exhaustively with this important subject, but to point out the close relationship which exists between chronic, often hidden, alveolar abscesses and certain painful, even serious states connected with remote structures or organs. In an empirical way clinicians recognized the connection between systemic disturbances and diseased processes in the gums or about the roots of the teeth, as long as twenty-five years ago, but the real significance of mouth infections has been made apparent only within the past few years through the bacteriological studies and experiments of laboratory workers mainly in Chicago, A. M. Moody, E. C. Rosenow, D. J. Davis, the clinician, Frank Billings, the surgical dentist, T. L. Gilmer, and others. Moreover, the development of röntgenology has made possible the exact recognition of hidden alveolar infections which previously could only be surmised or detected by extractions of the teeth. Finally, the investigations of bacteriologists have proved the existence of pathogenic organisms in such foci and of them chiefly streptococci, in particular Streptococcus viridans. Other bacteria are sometimes associated, as the anaerobic fusiform bacillus, or in the more acute alveolar abscesses, Streptococcus hæmolyticus, but in chronic blind abscesses it is Streptococcus viridans that is responsible for the constitutional symptoms.

The mere existence of this organism in the focus would probably not be a menace to health, but in the light of animal experimentation by Rosenow and others, it is apparent that the passage of the streptococcus from the abscess into the blood stream and its lodgment in distant parts is a source of positive danger to the individual aside from pain or invalidism. That obstinate neuritis, arthritis deformans, nephritis, muscular rheumatism, and general weakness may result from these alveolar abscesses is well known, but in this paper it is desired to emphasize the connection existing between myocardial incompetence and the kind of mouth infections of which mention has just been made.

*Read before the American Therapeutic Society, at Detroit, June 9, 1916.

That a streptococcus viridans endocarditis may result from the combination of a valvular lesion and an alveolar abscess may be reasonably assumed, although no such case has come to my notice, for, as we know, any focus harboring this streptococcus is a menace to the individual who has had a rheumatic endocarditis. But I desire in particular to direct attention to the possibility of invasion of the heart muscle by this organism, a possibility no more remote in the human subject than in the rabbit used in experimentation. Thus A. M. Moody, after injecting young healthy rabbits with diluted pus obtained from the teeth of one of the patients soon to be mentioned, found at the end of eight days in two, and thirteen days in two others, distinct evidence of the presence of streptococci in the myocardium as well as suppurative arthritis of the knees in some of the animals, subcapsular hemorrhages in the kidneys, and also hemorrhages in the maxillary and other muscles and in the wall of the stomach. Such experimental results shed light on the symptomatology of patients whose mouths show hidden abscesses about the roots of the teeth. Clinical corroboration of such experimental findings appears in the following cases.

Case I. Mrs. T., aged fifty-two years, seen in May, 1914, stated that she had been an invalid for two years because of general asthenia and weakness of the heart, for which her physician in Canada had kept her confined to the house, some of the time in bed. Ten days prior to consulting me, she had suffered such lameness of the muscles of the extremities and shoulders as to render her incapable of rising or turning in bed unaided. Examination of the heart disclosed no murmurs, but feebleness of tones, a moderate increase of dullness to left, with a systolic blood pressure of 130 mm. Hg. Her temperature was 99.2° F., and her leucocytes numbered about 17,000. The urine was negative. Her anamnesis was unusually free from acute infections, but the existence of one loose tooth in the lower jaw and of one crowned tooth led to a Röntgen ray examination, which disclosed a large alveolar abscess. Three teeth were extracted and the abscess cavity was evacuated of a pus so foul smelling that the nurse was obliged to leave the room; yet no suspicion of the presence of this focus had ever been entertained. Cultures showed Streptococcus viridans and an anaerobic fusiform bacillus. Under autogenous vaccines and other treatment improvement proceeded very slowly, owing probably to the existence of still another abscess in the upper jaw which was not discovered until several months later. This experience convinced me that films should be made of all the teeth and not merely of such as might be suspected. At last report this lady, though still somewhat lame, was going about quite free from cardiac symptoms.

Case II. Man, thirty-one years old, who because of anginoid chest pain had been told he had angina pectoris due to coronary sclerosis, the pain being so intense, he asserted, as to compel him to desist from walking. There was no history of acute infections, and two Wassermanns had been reported negative. Examination disclosed no murmurs, but moderate dilatation of the heart to the left, feeble tones, and a marked fall of systolic pressure after hopping in my office. Because of two suspected teeth, he was referred to a röntgenologist, with the added instruction to fluoroscope the heart before and after stair climbing. The x ray examination disclosed an alveolar abscess, and a marked dilatation instead of contraction of the heart after exercise. The extraction of the diseased teeth, the employment of autogenous vaccines made from the pus, treatment of the heart by rest and digitalis at length resulted in compensatory hypertrophy, as shown by a satisfactory response to exercise, and the almost complete disappearance of pain, so that the man could walk with slight discomfort. In fact, his pain now seemed restricted to one hyperalgesic spot directly above the heart, where firm pressure caused considerable pain. The result substantiated my opinion that the anginoid pain was not due

to coronary sclerosis, but was a myalgia or manifestation of myositis, the movement of the shoulder and pectoral muscles incident to walking causing aggravation of the pain and bringing the man to a standstill. Muscular tenderness persisted, but no longer suggested coronary angina.

Case III. Physician of fifty-two years, whose history, if detailed, would be found not only interesting, but highly instructive. The main facts were as follows: Tonsillitis, acute articular rheumatism, and complete freedom from such joint attacks since a tonsillectomy six years ago; a chronic arthritis of the sacroiliac synchondrosis necessitating the persistent wearing of a back support; two attacks of acute dilatation of the heart, the last one about two years ago followed by a low blood pressure and urinary findings suggesting nephritis; evidence in December, 1915, of moderate myocardial incompetence, with slight enlargement to the left, considerable general asthenia, and moderate stiffness and lameness of the muscles and joints. Convinced that some infective focus still existed, and that if it could be discovered and removed the heart could be restored to a fair degree of working efficiency, I instituted a thorough examination of the teeth. The physician had always suspected these of being more diseased than was apparent, or would be admitted by his home dentists or eight of his medical friends whom he had consulted. Films were made and these, when submitted to Dr. Thomas L. Gilmer, disclosed such a truly shocking condition as to necessitate the removal of all but four or five teeth in the lower jaw. Incidentally it may be stated that a well known Boston dentist refused to extract the teeth on the ground that they were not causing pain or fever. The pus in this case yielded Streptococcus viridans, and when injected into rabbits produced the topical lesions mentioned above.

Coincidently with the work on his teeth this physician underwent treatment addressed to a restoration of cardiac efficiency with the result that he now is free from symptoms referable to his heart, and has resumed his practice, though in a less strenuous manner than before. Also he is gradually losing his muscular rheumatism and his back is far less painful. Without ignoring the possible influence of his two attacks of acute articular rheumatism, I believe the mouth infection played a distinct role in this man's ill health, and that its removal was essential if he were to regain his ability to work.

Finally, without citing cases, I may state that in several patients alveolar abscesses have been found to be the cause of spasmodic asthma. One lady attributes her freedom from asthma to the removal of badly infected teeth followed by the use of autogenous vaccines made from the pus. Certainly it is quite reasonable to conclude that an alveolar abscess may be the focus from which is absorbed the foreign bacterial protein causing the anaphylactic phenomenon known as spasmodic asthma.

In conclusion, it may be stated that the successful therapeutics of cases such as are here outlined must suppose the total eradication of the infective focus by a surgical dentist, and in many cases the employment of vaccines made from the contents of the cavity. This, it is believed, is essential to the successful employment of other measures addressed to whatever organic or structural effects may have been caused by the bacteria in the diseased focus.

77 East Washington Street.

Observations on the Opsonic Index.—Wolf (*Journal of Infectious Diseases*, October, 1916), although not making dogmatic statements, finds that the opsonins can be increased by injections of the proper bacterial vaccines, and that this increase is associated with a favorable influence upon the infection.

TRADITIONAL FALLACIES ABOUT TUBERCULOSIS.*

By Maurice Fishberg, M. D.,
New York,
Clinical Professor of Medicine, University and Bellevue Hospital Medical College; Attending Physician, Montefiore Home and Hospital for Chronic Diseases.

Careful students of science often complain about the various fallacies which encumber learned publications, and textbooks on logic invariably devote pages to explanations of the nature of fallacious reasoning. Though based on painstaking and conscientious scientific research, applied medicine, including diagnosis, prophylaxis, and treatment of disease, very frequently meets with stumbling blocks because of assumptions made by some writers, past or present, leading to fallacies which are very difficult to eradicate. I believe I am not exaggerating when I state that medical literature, more than the literature of any other subject which lays claim to scientific accuracy, is apt to contain fallacies based on the assumption that, because of concomitance of time and place, two or more phenomena are caused by the same forces. Indeed, I would not be astonished to read in a medical paper or book that, inasmuch as during the past fifteen years motor cars have been increasing in number, and concomitantly poliomyelitis has been prevalent, there must be a causal relation between the two phenomena.

Tuberculosis, being the most widespread of serious diseases, is burdened with many more fallacies of this character than any other morbid process, perhaps because it has been treated more as a social malady than as a pathological phenomenon, and the social workers have taken a hand in the attempts at its control. As long as the fallacies are mere individual assumptions and opinions for discussion, they are, as a rule, harmless; they may stimulate research or contribute to the gayety of nations. In this particular domain, however, the numerous fallacies have wrought great harm to both patients and profession, and I believe that an enumeration and discussion of some of the more important of them may prove instructive.

Infection and disease. It has been noted from time immemorial that tuberculosis is apt to occur in several members of the same family. It was also noted that the disease at times appears in persons who have come in contact with consumptives. It was but natural that the inference should be drawn that it was transmitted from the sick to the well In former times numerous cases have been published in detail, showing that a consumptive infected several persons living with him under one roof. When, in 1865, Villemain proved conclusively that inoculation of tuberculous tissue into healthy animals produces tuberculous lesions, the proof was complete. And when, in 1881, Koch demonstrated the microorganism invariably found in tuberculous tissues, and that pure cultures of this bacillus may produce tuberculous lesions when inoculated, ingested, or inhaled, the proof was final.

In fact, soon after the discovery of the tubercle bacillus, great hopes were entertained that, knowing the biology of this microorganism, we should be able

*Read before the Eastern Medical Society, October 13, 1916.

to eradicate the disease forever. Considering that prophylaxis aims mainly at the prevention of *infection,* it appears that it has utterly failed in its aims. All energies have been directed toward killing the bacilli outside the human body, or preventing their entry into the body; yet the tuberculin test, as well as careful dissection of the human body after death, have shown that over ninety per cent. of human beings in large cities have been infected during their lifetime. Indeed, it is difficult to find a person who does not react to tuberculin, or in whom active, latent, or healed tuberculous lesions cannot be found when a careful autopsy is made.

When we speak of tuberculosis, we must always draw a sharp line of distinction between *infection* with tubercle bacilli, and *disease* which disables the victim, requires careful treatment, and perhaps kills.

It is a fact not generally known that not every infection with tubercle bacilli is followed by that train of symptoms which we call tuberculous disease in its various forms; it seems that the vast majority of infected subjects continue in good or fair health, and only exceptionally become sick, or die as a result of the infection. If this were not so, over ninety per cent. of humanity would be sick, and succumb to the various forms of tuberculosis. It appears that infection alone is, as a rule, powerless to produce consumption; there must also be an organism which is peculiarly predisposed; though we are still in the dark as to the nature of this predisposition.

Infection and reinfection. The most important fallacy about tuberculous infection is the belief that a person may be infected several times with the virus of this disease. In fact, the warnings given to consumptives are that they must not expectorate indiscriminately because they are likely to infect others, and they are explicitly told that they may reinfect themselves, and thus acquire new lesions in parts of the lungs hitherto unaffected. Tuberculosis is thus considered different from other infections, which can be acquired only once.

Recent research has shown, however, that tuberculosis is no exception to the rule in pathology, that one attack of a specific disease immunizes against further and renewed infection with the same virus. In fact, experimentally it is difficult or even impossible to reinfect a tuberculous animal with tubercle bacilli. That this apparently holds good as regards spontaneous tuberculosis in human beings, is clearly shown by certain facts proving that no person is ever infected with tubercle bacilli more than once. I shall cite some of them, considering the immense bearings they have on our attempts at the prevention of this disease.

We have good proof that inoculation of tubercle bacilli into the body of a human being hitherto free from this virus, is deadly. This is best seen in infants, who, when inoculated with tubercle bacilli, almost invariably succumb to acute general tuberculosis. It is also seen in adults who have never come in contact with tubercle bacilli, savage tribes, for example; they succumb to acute tuberculosis when infected. On the other hand, city dwellers, who come into daily contact with persons affected with this disease, and undoubtedly inhale the bacilli, which are ubiquitous, are spared and only exceptionally manifest active tuberculous disease. Similarly, bacteriologists and pathologists who frequently handle tuberculous sputum or tissues, are very rarely if ever infected. When inoculated accidentally, they are troubled with the so called "pathologist's warts," which are innocuous. Indeed, Klemperer and Baumgarten inoculated subjects with tubercle bacilli and no generalized tuberculosis was observed, but only local lesions akin to those we have just mentioned as pathologist's warts.

The explanation of this paradox in pathology is found in the fact, already mentioned, that nearly all human beings living in civilized countries have been infected with tubercle bacilli before reaching adolescence. In some, tuberculous disease has developed, but most have remained healthy and, in addition, have thus been immunized against reinfection. They are therefore safe when coming in contact with tubercle bacilli, which they cannot avoid, since they have not been eradicated by the strenuous campaign which has been waged against them.

The safety of adults as regards reinfection with tubercle bacilli is proved by the following uncontrovertible facts: The hospital staffs in institutions harboring tuberculous patients do not suffer from tuberculosis more than others. Even laryngologists, who are often coughed at while examining patients, are safe, as has been proved by carefully collected statistics on the subject. Of course, we find charming fairy tales in books and papers on tuberculosis about doctors, nurses, and others who have been infected through contact with patients; but close examination shows conclusively that none of them can be substantiated. Behring investigated a widely circulated story by an American physician, to the effect that several people in a city in the middle west were infected by reading books from a public library, but found it to be groundless. Most of the stories of hospital infection are of similar untrustworthiness.

It may be suggested that the rarity of tuberculous disease among hospital workers is due to the prophylactic measures which have been taken in these institutions during the past thirty years; but investigations have shown that in hospitals in which no precautions are taken in the disposal of sputum, and also in the hospitals during the first half of the nineteenth century, no excessive morbidity or mortality from tuberculosis was observed.

There is even better proof that adults are safe against infection with tubercle bacilli, though they are very liable to acquire the disease due to this microorganism. We are well aware of the ravages wrought by syphilis and gonorrhea among consorts when one contracts either of these infections. There is no doubt that over seventy-five per cent. of wives whose husbands suffer gonorrheal infection, contract the disease through intercourse; hardly any wife, unless immunized by a previous infection, escapes the ravages of syphilis when she comes into intimate contact with a luetic husband. We know that tuberculosis is even more easily transmitted than syphilis—the latter may be considered an inoculable disease—that it is as easily transmitted as is measles. Yet it is a fact than conjugal phthisis,

consumption in both husband and wife, is exceedingly rare.

I feel that many of my readers are rather startled by this statement. All have read in books and papers of the dangers of tuberculous infection, and carefully recorded cases in which tuberculous husbands infected their wives; all may have read about a husband who infected one wife; she died, and the villain married again, infecting his second spouse, and after she perished, he repeated his nefarious marital activities several times until Providence removed this incubator of tubercle bacilli, thus saving womanhood. There is no doubt that such isolated cases may be cited. Any one may have seen one or more cases in which both husband and wife suffered from consumption; but some have also seen rare cases of cancer, diabetes, appendicitis, etc., simultaneous or consecutive in husband and wife. I have recently seen a fracture of the femur in an old man, and three months later, his wife also sustained such an injury. To attribute such coincidences to infection is a fallacy due to ignorance of the facts.

In my long experience as physician for the United Hebrew Charities in this city I have never observed a case of tuberculosis transmitted from one consort to the other. This is despite the fact that our applicants are dependent, poor, underfed, and live as overcrowded as human beings in this city can. Most of the couples sleep in one bed, thus showing that they come into intimate contact, yet they do not transmit the disease to their consorts. They have children while sick with tuberculosis, and while most of their progeny become infected, the unaffected consort remains so indefinitely. J. Petruschky has recently named "mother immunity," a phenomenon which has been observed for generations by physicians. I refer to the frequently occurring cases in which a healthy woman marries a tuberculous man and has by him children that succumb to tuberculosis one after another, yet she is spared and remains in good health.

FALLACIES IN PROPHYLAXIS.

What is the explanation of these paradoxes? In former times such facts were cited as proof against the contention that tuberculosis is transmissible; but in the light of recent research we can no more cite cases in which the healthy consort of a tuberculous mate escapes infection as a proof against the infectiousness of tuberculosis, than we can state that because a person covered with pock marks is not infected by contact with a smallpox patient, this disease is not infectious.

We have already stated that nearly all persons living in civilized communities are infected with tubercle bacilli during childhood; we have also mentioned that infection with tubercle confers an immunity against endogenic and exogenic reinfection with the same virus. It is therefore clear that adults cannot be infected, and in our attempts at prevention of tuberculous disease in adults we need not employ the strenuous measures which have been taken by the authorities, as well as by the members of our profession during recent years.

When I speak of our modern methods of prophylaxis, I know that I am treading on dangerous ground. The work of the health authorities has become a fetich, and any one who suggests that some of the methods are fallacious is in the same danger as when he attempts to discuss critically some religious dogma. Indeed, before I proceed I know that many readers think of the great results attained by the campaign against tuberculosis, and feel satisfied that if the health department erred, it did so on the side of laxity. Indeed, it has been repeatedly stated that if the municipal, State, and Federal governments spent several millions a year along the lines laid down by certain savants, this country would be free from tuberculosis within ten or fifteen years.

The fallacy of these assumptions is clear when we consider that of late we have been spending more than twenty millions a year in preventive work, for hospitals, sanatoriums, and dispensaries, as well as for literature and salaries of those engaged in the vigorous "campaign" against the White Plague, and the disease is still with us, presenting the same problems as before the campaign was inaugurated. Those who want to point to the declining mortality as proof of the utility of the campaign should bear in mind the following facts: The mortality began to decline long before the fight was begun. Statistical facts from the registrar's data of England, and many States in this country prove this conclusively. Moreover, the decline has been observed in countries where no campaign has been waged. In Ireland, France, Italy, Norway, etc., where measures have been taken to prevent the disease, the mortality has not at all declined. In Belgium it has declined, while in France it has not.

Considering that the campaign has not produced the results which its votaries have ascribed to it, it is but just to ask whether it should be continued. Inasmuch as adults cannot be infected with tubercle bacilli, it is problematical whether the vigorous "follow up" system practised by the health department in this city is justified. If a tuberculous husband cannot infect his wife we may assuredly conclude that a tuberculous workman cannot infect his neighbor in the factory. It is therefore a vain, and often a cruel procedure to exclude tuberculous workmen from factories, as has been done by the authorities and the labor unions of this city.

The methods of those engaged in the campaign against tuberculosis are often not only fallacious, but also dangerous to individual patients as well as to the community. It is a great injustice to exclude from human intercourse and activities one whose sputum has once shown tubercle bacilli, although he feels healthy and well able to work; to "follow him up," to send after him inspectors, doctors, nurses, relief workers, charity investigators, and others who visit not only his home, but also his place of employment, and warn all those who may come in contact with him. The same stupid bureaucrats teach that a consumptive who is careful, i. e., who disposes properly of his sputum, is not at all dangerous even to infants and children, which is decidedly fallacious. The truth is, that it is very dangerous for an infant to remain in the same room with a person suffering from active tuberculosis, no matter how careful he may be.

FALLACY OF HEREDITY.

One of the most widespread fallacies with which many physicians are obsessed, is that the disease is apt to run an acute or malignant course when it attacks a subject derived from tuberculous stock, whose parents or grandparents have suffered from, or succumbed to the disease. Recent careful statistical investigations have shown clearly that there is no foundation for this belief. In fact, it has been demonstrated that patients from tuberculous stock, when attacked by tuberculosis, are apt to suffer from the chronic type of the disease which runs a mild course, while those whose parents were free from tuberculosis, and have lived in an environment free from tubercle bacilli, are more likely to suffer from the acute or subacute forms of the disease. This is best seen in young men or women in the large cities hailing from rural districts. When attacked by tuberculosis they succumb, as a rule, more or less quickly.

A similar fallacy is entertained about subjects who have suffered from scrofula, or tuberculosis of the glands, bones, and joints during childhood. They are always warned that the sword of Damocles hangs over their heads, that they are particularly likely to have phthisis, and I know of many who have been so terrorized that they are in constant fear of consumption. The fact is that just this class is relatively immune. Just think, how rare it is to see a consumptive who shows scars which are the result of glandular, osseous, or articular tuberculosis during childhood.

FALLACIES IN DIAGNOSIS.

There is one fallacy which is responsible for a considerable part of the distrust of the laity for the medical profession. I refer to the belief that if tuberculosis was invariably detected in its incipient stage, all patients would be cured. Most patients in the advanced stages of the disease blame their first doctor for all their troubles, and substantiate their grievances by the literature published by the societies for the prevention of tuberculosis in which it is distinctly and unequivocally stated that to cure the disease, it must be detected in its incipiency, nay, in the so called "pretuberculous stage," which can be done by the proper physician in all cases.

It is a clinical fact, however, that these propositions are not altogether true. I do not know of a single physician who, after applying all the scientific and empirical tests at the command of medical men, can tell who is likely to acquire tuberculous disease, on the one hand, and who has sufficient resisting power to carry him through life without this malady on the other. I say this, knowing well that medical men are apt to tell some patients that they are "strongly predisposed to lung disease," and that unless vigorous measures are taken in time, there may be good reasons for regrets.

Moreover, it is impossible to detect the so called "pretuberculous stage," and in many cases it is more than difficult to detect active disease in its incipient stage. If we adopt the methods of diagnosis pursued by admitting physicians in sanatoriums, and consider every person who coughs, loses flesh, etc., and shows no other cause for such symptoms, suffering from a case of incipient tuberculosis, we shall detect thousands suitable for treatment; and we should fill sanatoriums with even larger numbers of patients who do not belong there. We must remember, however, that a diagnosis of tuberculosis should be made only when there are uncontrovertible proofs of the existence of active disease, and it is not always possible to discover these during the first visit of the patient. Indeed, in many cases it is necessary to keep the patient under observation for weeks before a diagnosis is arrived at.

But even if we could diagnose all cases in their incipiency, i. e., as soon as the patient begins ailing, we should not save many more than we do at present. Many cases, called acute, are advanced as soon as treatment is begun, and, no matter what is done for them, they perish within a short time. Others are subacute, and all treatment in vogue at present does not help them—they pursue a more or less rapid course and end fatally sooner or later; even sanatoriums, specific, dietetic, and climatic treatment fail to cure them. A very large proportion is of the chronic type. The patients last for years, and suffer from several acute or subacute exacerbations, interspersed with several periods of "recovery." They are admitted to sanatoriums several times, each time as presenting incipient or moderately advanced cases, and no sooner are they discharged, as cured or with arrested disease, than they suffer relapse and have to be readmitted.

That it is not promptitude of recognition and the application of treatment which are always responsible for the cure of pulmonary tuberculosis, is clear when we bear in mind that autopsies show conclusively that more people recover from tuberculosis without treatment than suffer and perish from the disease. The belief that promptness in recognition and treatment of tuberculosis will eradicate the disease, is fallacious, and the sooner we realize this fact, the better for the patients and the profession.

FALLACIES OF PHYSICAL DIAGNOSIS.

A fallacy difficult to eradicate is that to diagnose tuberculosis in its incipient stage the physician must be a virtuoso in physical diagnosis. This is one of the main reasons why so many cases are not recognized in time. But as a matter of fact the diagnosis of early phthisis is made by considering first the constitutional symptoms; the signs elicited by percussion and auscultation only localize the lesion. Physical examination of the chest alone is usually inconclusive unless there are constitutional symptoms, such as cough, fever, night sweats, anorexia, tachycardia, etc. Without these symptoms, there may be signs of airless areas in one or both pulmonary apices shown distinctly by physical signs or the radiogram, yet the patient is not afflicted with an active tuberculosis requiring prolonged and costly treatment. In fact, I may say that, in attempting to diagnose early phthisis, if I had the choice between symptoms and signs, i. e., between inquiring into, and observing the constitutional symptoms on the one hand, and making a physical examination, and a radiographic plate of the chest, on the other, I should feel much safer when considering the data supplied by the former rather than those by the latter. This is a fact which general practitioners should bear in mind, because every physician is competent

to study the constitutional symptoms of early phthisis, even though he may have to ask a colleague to localize the lesion.

TUBERCULOSIS IN CHILDREN.

Because it has been found that nearly all infections with tubercle bacilli take place during childhood, those engaged in the campaign for the control of the disease have maintained that if the disease is to be prevented at all, children are to be protected first. But here the fallacy of confounding *infection* with *disease* has again manifested itself, and when a child coughs, loses flesh, sweats at night, etc., and the tuberculin reaction is positive, a hasty diagnosis of tuberculosis is made, the little patient is prohibited from attending school, and often prolonged and costly treatment is instituted.

It is a fact, however, that while extrapulmonary tuberculosis is rather common in children of school age, real pulmonary tuberculosis—*chronic phthisis*—with lesions similar to those seen in adults, is exceedingly rare. When examining many thousands of children descended from tuberculous parents, I hardly saw a dozen cases of chronic pulmonary tuberculosis in subjects under twelve years of age. To be sure, pulmonary tuberculosis is frequently seen in infants under two years of age in the form of tuberculous bronchopneumonia, but between two and twelve years of age, if tuberculous disease occurs at all, it is of the osseous, articular, and glandular types, the tracheobronchial glands are especially apt to be affected.

Children with tracheobronchial tuberculosis, however, are not all in danger; death due to this cause is so rare that it may be disregarded when formulating a prognosis in the average case. Nor are these little patients a menace to those associating with them because, as far as we know at present, they do not disseminate the bacilli. As to whether they are all destined to suffer from phthisis in later years, we cannot answer with certainty. One view, supported by recently discovered facts, is that they are rather benefited by the mild infection with tubercle bacilli; indeed many authorities speak of "benevolent infection" which immunizes them against renewed exogenic reinfection. These are the infections which protect adults when they come in contact with persons suffering from open pulmonary tuberculosis.

It is a fallacy, therefore, to treat every sickly, underfed child as tuberculous; even when the tracheobronchial glands are discovered to be enlarged, there is no reason for prohibiting school attendance, or to institute prolonged and costly treatment, except such measures as will enhance the nutrition of the child. We must not interfere with a child's opportunities to acquire an education, except in extreme cases, and tuberculous infection in children of school age is rather harmless. This fact has been realized only during recent years. Some six or eight years ago, when the cutaneous tuberculin test was considered a valuable diagnostic procedure, a positive reaction was considered a sure indication of tuberculous disease in a child of school age. When we found that over seventy per cent. of children gave positive reactions to tuberculin, we ceased to consider it of importance.

FALLACIES IN PROGNOSIS.

A fallacy amounting to more than a superstition is the fear of pulmonary excavations, and the ill omen always feared when a cavity is diagnosed in a tuberculous patient. The truth is, that in chronic cases the best that can happen to one with an extensive lesion is that the diseased area should be eliminated by expectoration, leaving a cavity surrounded by a connective tissue capsule. Many patients with such excavations live for years in comparative comfort and efficiency. Moreover, often the acute cases of pulmonary tuberculosis succumb before excavation has taken place owing to rapid extension of the process, toxemia, etc.

THERAPEUTIC FALLACIES.

We now come to the therapeutics of tuberculosis, in which there are traditional fallacies which should not be omitted when discussing the subject. We know that nearly all remedies vouched for as being efficacious in the treatment or cure of phthisis, be they medicinal, specific, dietetic, climatic, or institutional, work wonders in selected cases. And they really do. Even the "grape cure" and the "song cure" have to their credit quite a comforting proportion of recoveries. A survey of the literature on tuberculosis for the last one hundred years shows that nearly all the remedies suggested have cured about sixty per cent., and improved about twenty-five per cent. of really incipient cases, while in only from ten to fifteen per cent. were they impotent, and the patients remained sick or died despite the treatment. Moreover, we have been told by each sponsor for a new remedy, that some twenty-five to forty per cent. of advanced cases were benefited by his treatment. These are the kind of statistics which we read in the annual reports of most sanatoriums; we also find them in the writings of those who, some twenty years ago, extolled creosote or its derivatives, and today again those who advocate tuberculin report similar results.

That the laity is impressed by such statistics is not astonishing, considering that to them tuberculosis is a fatal disease invariably, unless treated in time and properly. As a rule, however, these statistics have a like effect on medical men, and in this manner creosote, arsenic, iodine, allyl, ichthyol, mercury succinimide, and a host of other drugs gained reputations in their day, and for several years after their introduction were considered specifics. I can unhesitatingly add that the success of the modern specific treatment, of various climatic regions, and of the sanatoriums as at present conducted, etc, depends on such statistics. I suspect that without the normal tendency of tuberculous lesions to heal, the sanatoriums would have to close their doors.

Close analysis shows clearly the fallacy of testing statistically a remedy for tuberculosis. The fact is that, without treatment, five years after the onset of the disease, over fifty per cent. of patients suffering from pulmonary tuberculosis are alive and more or less efficient at their occupations. For this reason, any one who has a new remedy for this disease, provided that the therapeutic agent is otherwise harmless, may count on being able to prove that fifty per cent. of his patients will survive more than five years. If he asserts that only selected

cases are suitable for his cure, provided of course that he is an experienced clinician, which is rare with this sort of discoverer, he may prove that seventy-five per cent. of the cases are benefited. In fact, he may use distilled water, bread pills, or even prayer, and he will get the same results.

Here we have the cause of the many cures for tuberculosis which are introduced annually; this fact is responsible for the large number of people who believe they have discovered safe and sure remedies for the disease, and pester us for help to establish their claims to immortality, and incidentally to the material gains which go with a cure of a disease from which about one seventh of humanity suffers. It appears, however, that these remedies almost invariably work only during the first two or three years after their introduction, and it has been suggested that tuberculous patients should hasten to take a new cure immediately upon its introduction: delay may mean disappointment—the remedy is sure to lose its beneficial effects.

Another class of remedies against which we should be on our guard are those which are stated to work best in cases of osseous, articular, and glandular tuberculosis, and it seems that during recent years nearly all cures have been said to work well in "incipient" pulmonary tuberculosis, but that they were almost infallible in disease of the bones, joints, and glands. In these forms of the disease, we can guarantee that practically no mortality will be observed, because it is very rare that a patient dies from tuberculosis of the glands, bones, or joints, unless a radical surgeon operates. The fallacy consists in forgetting that in extrapulmonary tuberculosis, except of the meninges, the prognosis is good. The patient may remain disfigured or crippled for life, but he does not die from the disease.

COLUMNAR AMNIOTIC EPITHELIUM.

Its Clinical Significance,

By Herbert K. Thoms, M. D.,
New Haven, Conn.

The amniotic epithelium covering the placenta at term is usually stated to be of one type—namely, cuboidal. That this epithelium may be either columnar or cuboidal, depending upon early or late rupture of the membranes, it is the purpose of this paper to demonstrate.

During the past year, while the author was engaged in carrying on the routine examination of placentas in the obstetrical and gynecological laboratory of the Yale Medical School, his attention was called to the fact that occasionally a type other than that of the so called normal variety (cuboidal) was present. Bearing in mind this possibility, great care was used to preserve the epithelium if possible in a series of placental sections with a view to determine the incidence of any variation from the cuboidal epithelium covering the full term placenta.

It has been my observation that in the great majority of placental sections seen in different clinics, the amniotic epithelium covering the placenta is usually lacking. This is no doubt due to the fact that it is very easily separated during the process of cutting, hardening, and imbedding. In some specimens, even with great care, I have found it almost impossible to preserve the epithelium for purposes of study.

The picture of cuboidal epithelium covering the placenta is too well known to require elaborate description. We have a single layer of cuboidal cells resting on a basement membrane which is immediately adjacent to the subamniotic connective tissue. The nucleus, which is large and spherical, is situated at or near the centre of the cell (Fig. 1).

The picture presented by the columnar type is essentially as follows. The epithelium is of the high columnar type, and in the majority of cells the cell base seems much narrower than the free border of the cell, giving a pressed in or squeezed appearance. The nucleus is as a rule situated at the extreme end of the cell near the free border. In places they are more or less elongated and otherwise distorted from the spheroid type (Fig. 2). Occasionally in very high cells the nucleus seems to have burst the end of the cell and left a craterlike appearance at the free edge (Fig. 3). This appearance gives the observer a further idea of some sort of cell compression having taken place.

In the study of 100 placentas during the routine

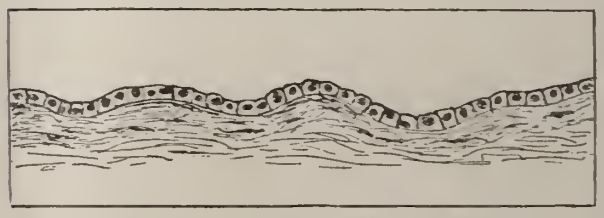

Fig. 1.—Cuboidal type of amniotic epithelium covering placenta.

examination, columnar epithelium was noticed sixty-nine times, grading from low columnar types to the extreme high variety. The remaining thirty-one placentas presented cuboidal epithelium.

The marked incidence of this columnar type must demand some explanation for its occurrence, and some mechanical process by which the cuboidal type is changed at once suggests itself. That the amniotic epithelium covering the placenta at the onset of labor in all cases is cuboidal is presumably well established. In three of the thirty-one cuboidal variety the placenta was studied with the same conditions as regards mechanical pressure that would obtain at the onset of labor, i. e., before labor pains had begun; one case of premature separation of the placenta at term, and two cases of Cæsarean section at the onset of labor. In all these epithelium was distinctly cuboidal, as we should expect.

Having then a change in cell type presumably due to a mechanical force, the question arises regarding its source and application. That contraction of the uterus during severe labor pains exerts pressure upon the fetal surface of the placenta must be granted. This force, while the membranes are still intact, is, on account of the liquor amnii, of course exerted equally in all directions, and no change in epithelium due to any mechanical compression can

be expected. When the membranes have ruptured, however, and the liquor amnii drained away, severe uterine contractions may distribute the force upon the placenta in an entirely different way. Here we should certainly expect surface compression to a much greater degree than when the membranes were intact.

Granting this possibility, we should then expect to find, in cases of early membrane rupture, columnar epithelium to be the rule, and in late rupture or rupture at birth to find undistorted or cuboidal epithelium. In a special study of forty-five cases of the series these facts obtained. In thirty-five cases in which the presenting type was columnar, the membranes ruptured three or more hours previous to birth in twenty-one instances, one to three hours in

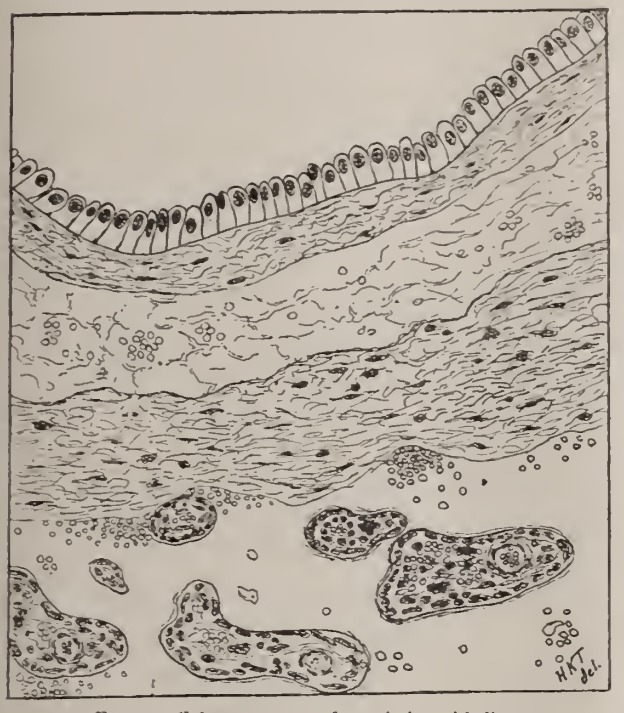

FIG. 2.—Columnar type of amniotic epithelium.

twelve instances, and in the remaining two, one half hour and three quarters of an hour respectively.

In ten cases in which the type was cuboidal, the membranes ruptured at birth in three instances, ten minutes before birth in three instances, fifteen minutes before birth in two instances, forty minutes in one instance, and eight hours previously in the remaining instance. This last case, in which the membranes were said to have ruptured eight hours previous to birth, is interesting. In order to preserve the cuboidal type according to the foregoing explanation, the liquor amnii could not have escaped entirely. It is probable, if the membranes actually did rupture at the stated time, that the head descended almost immediately, forming a ball valve and thus holding *in utero* the greater part of the liquor until at or near the moment of birth.

From the foregoing findings the following deductions may be drawn: In cases in which the membranes have ruptured at least two hours before birth and the amniotic fluid has escaped, the amniotic epithelium covering the placenta will be of the columnar type. This change may also be expected in cases in which the liquor is unusually scanty and the contractions are severe, even though the membranes have ruptured late. This fact I have not as yet determined. On the other hand,

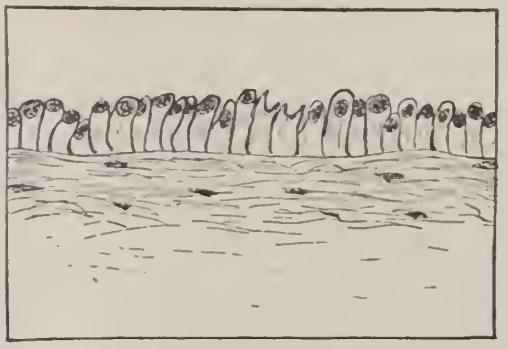

FIG. 3.—Two columnar cells, showing crater appearance after extrusion of nuclei.

in cases in which the liquor is normal in amount and in which the membranes have remained intact until at or near the time of birth, the amnion covering the placenta should present epithelium of the cuboidal type.

It is not within the scope of this paper to take up the study of amniotic epithelium under various pathological conditions, but it is interesting to note that in cases of hydramnios the amniotic epithelium usually presents a flattened or squamous type. This is well known and shows the effect of long continued pressure exerted directly upon the surface of the placenta.

During the study of the series, the problem presented itself whether or not in a well marked instance, different portions of the same placenta might not show variation in the type of cell present; this was not noticed in any instance. Sections cut from different portions of the same placenta always showed the prevailing type. By way of ex-

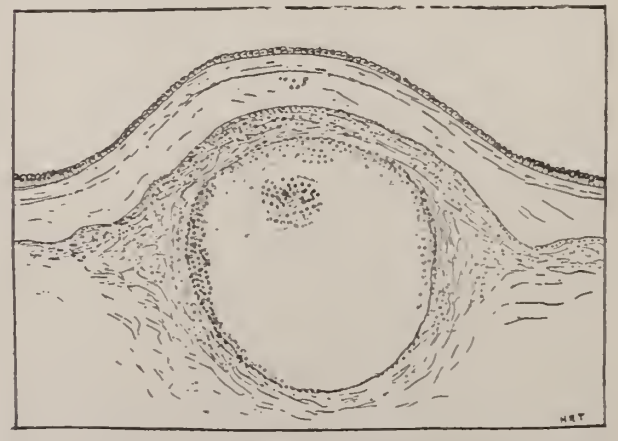

FIG. 4.—Cross section of vessel near surface of placenta, showing preservation of cuboidal type.

periment, in one placenta where the epithelium was distinctly columnar and the cord centrally inserted, a cut was made in the gross specimen completely through the centre of the placenta and cord,

and by means of careful sectioning the epithelium over the entire cut surface was studied. The findings were as follows: At the periphery of the placenta near the membrane attachment the type was cuboidal for a very short distance. The entire fetal surface showed columnar epithelium throughout, except at the insertion of the cord and over the large vessels near this point. Here, owing to the support given the epithelium by these underlying structures, the epithelium retained its cuboidal shape. In the study of all columnar sections where the cross section of a large vessel is found at the surface, the epithelium, as a rule, immediately over the vessel remains unchanged (Fig. 4). Here the vessel wall gives support to the overlying cells and admits of only slight compression, if any, during contraction of the uterus. It will be noted that the transition is not an abrupt one, but is more or less gradual as would be expected.

Two of the cases studied presented placental bacteriemia, that is, after premature rupture of the membranes, the placenta became infected. In both cases the rupture was very early, one or two days previous to delivery; in both cases also bacteria were easily demonstrated in great abundance in the

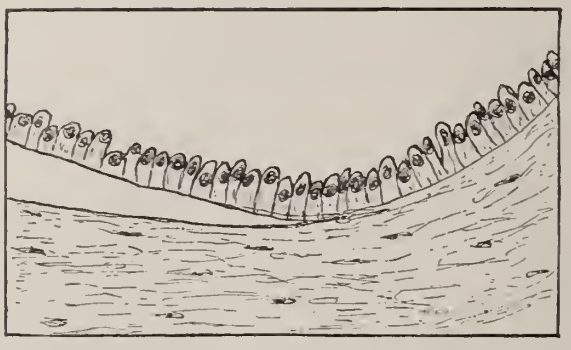

Fig. 5.—Showing stripping of epithelial layer.

subamniotic connective tissue by means of the Gram-Weigert stain.

In one case in which several sections were made no epithelium of any kind was found, and the whole subamniotic connective tissue showed intense leucocytic infiltration and swarms of bacteria. In the second instance some of the sections showed high columnar epithelium and some showed an entire lack of this layer. In one section (Fig. 5), a layer of columnar cells was found in the process of stripping from the subamniotic connective tissue. Bacteria were not demonstrated in any of the epithelial cells, although careful search was made. The leucocytic infiltration was found to be as marked under apparently normal columnar epithelium as in places where this layer was lacking. I am of the opinion that unless we have an actual stripping or a break in the amniotic epithelium, bacteria cannot by this route find their way to the placenta, and that infiltration noticed under apparently normal columnar epithelium is but an extension in the subamniotic space of an infective process from some nearby field where the epithelium has been cast off and the bacteria have gained a foothold.

OXYGENATED MILK.*

By Clifford G. Grulee, M. D.,
Chicago.

In 1903, there appeared in *Milch Zeitung* an article on a process of sterilizing milk by means of hydrogen peroxide. This work had been used in Copenhagen under the direction of Doctor Budde, and is commonly known as the Budde process. The process as outlined in this article was as follows: To each litre of milk 0.9 gram of hydrogen peroxide was added. This was mixed thoroughly and kept at about 50° C. (122° F.) for five or six hours. The statement is made that bacteria can be grown only after the effect of the oxygen wears off. The theory of this process was that the catalase enzyme of the milk split the hydrogen peroxide into oxygen and water, the nascent oxygen acting as a sterilizing agent. The efficiency of this process, so far as I know, has never been questioned. There has been a question raised, however, as to whether it would be possible to market milk at a low figure which had been treated by this process, the expense of which would be rather great.

In March, 1915, Mr. N. D. Neilsen, a Danish milk chemist, came to the Presbyterian Hospital, Chicago, and asked to be allowed to demonstrate a process similar to the Budde process which he felt could be commercialized. He arrived at an understanding with Mr. Bacon, the superintendent, and myself, and placed a plant in the hospital at his own expense. The plant was on a small scale similar to the one shown in the plan. It was his desire to have a milk which could take the place of certified milk, be perfectly safe for children and infants, and at the same time distinctly reduce the cost. From the beginning, the man and his proposition appealed to me, and I seconded his efforts. His process is as follows: In the first place, good raw milk is obtained directly from the farm in ten gallon cans, as accurately four per cent. as possible. This milk is treated with hydrogen peroxide, one quart to twenty gallons (a litre of hydrogen peroxide to eighty litres of milk). This milk is then heated to 122°-128° F. for one half hour, being stirred by a fan in the reservoir so that it is kept in motion the whole time. It might be stated here that the reservoir in which this is carried out is connected with the hot water apparatus of the hospital, the fan being run by water power. The milk is then withdrawn and bottled hot. It is then kept on ice until used. The theory of the action here is the same as that of the Budde process. I have therefore termed the milk "oxygenated milk" in order to do away with any misunderstanding of the process. In one sense of the word this is a preserved milk, but it is a preserved milk without preservatives, because at the end of a half hour's treatment only a trace of the hydrogen peroxide can be obtained. At first we had difficulty in obtaining pure hydrogen peroxide, but this difficulty has been overcome, and practically all danger from the hydrogen peroxide as such may be discounted. Bacteriological examinations have been carried on with this milk by Dr. B. O. Raul-

*Read before the American Therapeutic Society, seventeenth annual meeting, Detroit, Mich., June 9, 1916.

ston, resident pathologist at the Presbyterian Hospital. His results I submit herewith:

PATHOLOGIST'S REPORT.

Cultures were made of the usual stock supply of milk to the children's ward before and after it had been treated with hydrogen peroxide in the usual manner. Plates of the raw milk contained bacteria in the proportion of 3,250,000 per c. c., while those of the oxygenated milk remained sterile, except in one instance when there appeared approximately 100,000 streptococci per c. c. The bacteria which appeared in the cultures of raw milk were chiefly streptococci, colon bacilli, and staphylococci.

Specimens were then taken from the stock supply of milk in the diet kitchens, which is pasteurized milk, and cultures of it contained bacteria similar to those found in the raw milk and in the proportion of 3,000,000 per c. c. This milk was then oxidized and similar cultures were made, but no bacteria grew during seventy-two hours of incubation.

Known virulent strains of hemolytic streptococci, typhoid, and diphtheria bacilli were then added to separate specimens of raw milk. One loopful of a heavy suspension of the organisms was added to ten c. c. of salt solution and 0.1 c. c. of this dilution added to each 100 c. c. of the milk, which was then treated with peroxide in the usual way. Cultures of the milk containing streptococci were made on blood agar plates, of that to which typhoid bacilli had been added on litmus lactose agar and blood agar; and of the part containing diphtheria bacilli on Loeffler's serum, plain, and blood agar. All of these remained sterile during seventy-two hours of incubation, while blood agar plates of this same milk previous to oxidation contained from 2,500,000 to 3,000,000 bacteria per c. c.

Cultures of the stock of milk supplied to the children's ward of the hospital have been made at four different times

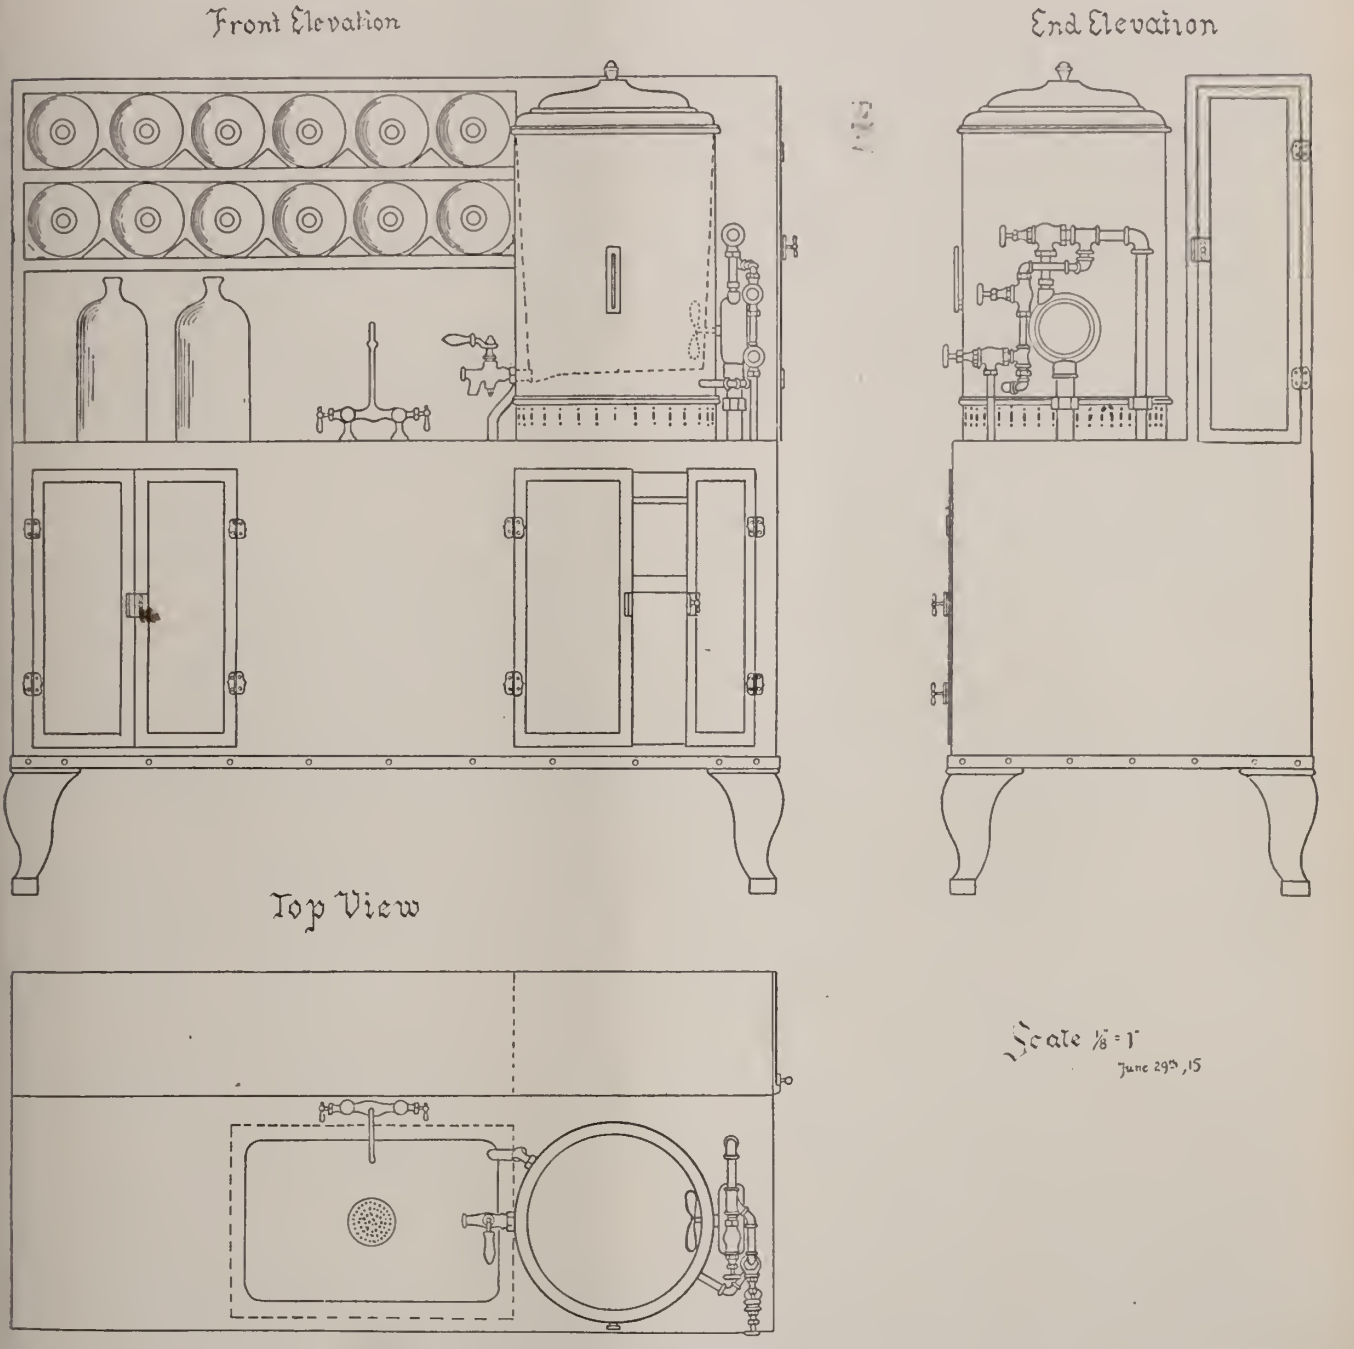

FIG.—Details of apparatus for preparing oxygenated milk.

recently, and in each instance the sample taken before the process of oxidation had been applied gave large numbers of colonies on blood agar plates, while that taken after oxidation gave no colonies, except in the one instance noted above.

Further examinations are being made. The chemical changes produced have not been so definitely studied. It would be impossible without the most expert chemical analyses to be able to determine minute changes in the character of the salts and perhaps of the organic constituents of the milk. It can be said, however, that no gross changes have been noted. Cream rises on this milk as on other milk, and all the digestive processes, such as the coagulation with rennin and the usual digestion with pepsin, occur as with raw or cooked milk. Theoretically the chemical change is only a destruction of the catalase enzyme in the process of splitting the hydrogen peroxide. We have noted no changes from ordinary raw milk in the preparation of infant foods, except, of course, in the preparation of soured milks, such as buttermilk. Here the presence of oxygen inhibits the growth of the bacteria, and makes it impossible to prepare buttermilk from the oxygenated milk.

After the use of this milk in the wards of the hospital for over a year, the number of patients daily in the infants' ward varying from twelve to twenty, and in the children's ward from twenty to twenty-five, together with ever increasing use of the milk throughout the hospital, we have never had reason to think that anything had developed which could be ascribed to a deleterious influence of the oxygenated milk. Our feeding cases have apparently done as well as did those previously fed on certified milk. The personnel in charge of the wards has not changed, so that we are able to make accurate comparisons in this respect. One of the advantages of the oxygenated milk is that with its use in the infants' diet kitchen, we have fresh milk at any time of the day or night, and the diet nurse can start as early in the morning as she wishes, and is not subjected to a delay because of late delivery. This milk has stood at room temperature as long as two weeks during the summer months without souring.

CONCLUSIONS.

1. It would seem from our experience that oxygenated milk has a definite place in hospital régime. It offers us the safest milk from all standpoints at a very much lower cost than that at which certified milk—to which it compares very favorably—can be obtained (about six cents a quart).

2. There is always fresh milk to be had, a great advantage to a diet nurse who is in a hurry.

3. All danger of infection from pathogenic organisms in the milk is removed.

4. There is no danger to the infants from sour milk which contains no specific pathogenic microorganisms, whatever this danger may be.

Whether it would be possible to market this milk on a large scale, or whether this would be desirable, I am not willing to put myself on record. Certain things have led me to think that this could be done and possibly to advantage. That it has worked out to our entire satisfaction in the Presbyterian Hospital of Chicago I have no hesitation in asserting.

OZENA.*

A Summary of Recent Studies Relative to the Etiology and Treatment,

By Henry Horn, M. D., F. A. C. S.,
San Francisco,

And Ernst Albrecht Victors, M. D.,
San Francisco.

(From the departments of Rhinology, and of Pathology and Bacteriology, San Francisco, Polyclinic and Postgraduate School of Medicine.)

In a recent paper (1) this subject was presented by us in detail, and it is purposed here to give a brief summary of our studies and conclusions, with special reference to the bacteriological consideration of the so called Coccobacillus fœtidus ozœnæ of Perez.

The previous publications of Perez (1), Hofer (2), Guggenheim (3), Horn (4), and Burkhardt and Oppikofer (5), have all erred in their description of certain morphological and biochemical characteristics of the organism. M'Gowan (6) described certain sugar reactions induced by the organism, but strangely failed to observe its motility.

Briefly described, the morphological and biological characteristics of the Perez bacillus as determined by us are:

Two types of organism are encountered—a distinct coccoid rod and a longer, heavier bacillus (0.75 and 1.5 by 0.4 and 0.6); stains with ordinary dyes, uniformly Gram negative; never spores or capsules; never in chains in fluid medium. Agar plate colonies (twenty-four hours) are round, slightly elevated, one to two mm. in diameter, and resemble young Bacillus coli colonies. In plain broth a diffuse turbidity is produced. Granular deposit in several days. No scum formation. A sickening odor is given off, but is uncharacteristic. The organism is definitely motile in all instances. Motility usually slow, with marked activity of occasional organisms. Some cultures show active typhoidlike motility of all organisms. Six to eight flagella are demonstrable. Gelatin is not liquefied. Growth on potato is characteristic. In forty-eight to seventy-two hours growth becomes distinct and raised, surface uneven and coppery yellow in color. Litmus milk usually acquires acidity with coagulum. Acid production is slow and rarely occurs before forty-eight or seventy-two hours. Occasional cultures produce no change. Carbohydrate fermentation is not fastidious. Dextrose is most readily cleft with the development of from ten to fifteen per cent. gas and about three per cent. acidity. Lactose is usually uninfluenced. Maltose, mannite, and saccharose are variably and indifferently fermented. Reduction of nitrates to nitrites was effected in about half of the cultures examined by us. Anaerobiosis is readily effected. In fermentation tubes both arms are at first uniformly turbid, with increasing turbidity of the open arm.

Comparison with Bacillus bronchisepticus. The studies of Ferry (7), M'Gowan (8), and Torrey and Rahe (9) concerning the etiology of canine distemper determine conclusively that Bacillus bronchisepticus is the causative agent of this malady. A striking similarity exists between this organism and the coccobacillus of ozena. Both organisms are readily grouped according to nitrifying and nonnitrifying ability. Both are Gram negative, motile rods, of like size and shape, and both divisible into a coccoid and more bacillary type. Pleomorphism is more common with the bronchisepticus, and long chains may develop in broth and medium. Agar plate and stroke colonies are macroscopically indistinguishable. Culture on potato is a characteristic raised copper yellow growth for both organisms, although the Perez organism is more tardy in this development.

The most apparent biochemical difference of the organisms is in their behavior toward carbohydrates, reaction changes, and oxygen demand. Bacillus bronchisepticus

*Read before the twenty-second annual meeting of the Urological Society, White Sulphur Springs, W. Va., May 5, 1916.

ferments no sugars and produces no acid. It produces a characteristic increase in the surface alkalinity of litmus milk. Although it may develop in an oxygen free environment, its growth is weak and the organism may be considered as a fairly strict ærobe. The coccobacillus of ozena, on the other hand, facultates with ease. Comparative fermentation tubes present a clear, closed arm with bronchisepticus and a turbid arm with Perez.

Another striking feature common to both organisms is their effect upon animals during immulogical procedures. Both organisms are highly toxic in killed suspensions, while suspensions of live organisms are borne in relatively large doses intravenously. Bacterial infarcts are produced which do not suppurate. Antiserum is readily and rapidly produced. Animals rapidly lose in appearance and weight and ultimately succumb to inanition.

AGGLUTININS AND COMPLEMENT DEVIATIVES.

A potent agglutinating serum is readily produced by immunization of rabbits with living organisms. The agglutinating titre reached one to 1000-2,000 for homologous strains, a relatively lower titre for allied strains. Perez bacillus antiserum is ineffective for cultures of Bacillus bronchisepticus, even in low dilution.

Complement is also readily deviated with antiserum of any strain, using filtered autolysate of the ozena coccobacillus as antigen. So also is complement deviated with Perez antiserum, using a filtered autolysate of Bacillus bronchisepticus as antigen. This demonstrates beyond question the similarity in the protein structure of both organisms.

CLINICAL OBSERVATIONS.

Of eighty cases of ozena of all types observed by us, forty-nine were diagnosed as true clinical ozena and selected for special study. Of this number the coccobacillus of ozena was isolated in thirty-seven instances. In the remaining cases (12) the Abels or some member of the Friedlander group was isolated. It is of interest to note that in certain instances of apparent Abels bacillus infection the Perez bacillus ultimately was isolated after the administration of a vaccine of this organism.

In isolating the organism, cultures are best taken from the anterior end of the middle turbinate after removal of crusts. Small crusts may be used as inoculating material, but these render recovery of the organism in pure culture more tedious. We have recovered the organism in pure culture by submucous aspiration. Blood cultures, except for inoculated animals, have been negative.

VACCINE THERAPY.

Thirty-two cases of typical clinical ozena have been treated by us with coccobacillus ozena vaccine. To avoid a possible conflict of the efficacy of various therapeutic agencies, no other treatment was instituted or allowed. In a small percentage of these cases the bacteriological findings were Abels or Friedlander bacilli with negative Perez bacillus findings. These cases were nevertheless treated with coccobacillus ozena vaccine.

The vaccine used was polyvalent, several groups of strains being incorporated. As our work progressed the more dissimilar strains were assembled after animal passage. To sustain the virulence of the organism and for the insurance of fresh bacterial suspensions, we have established a routine procedure of animal passage, recovery and suspension, so that a fresh potent vaccine was at hand at three or four weeks' interval.

Vaccine administration was instituted with 125,000,000 as initial dose and increased 100,000,000 every third or fourth day until some evidences of reaction were manifest. A reaction occurred not infrequently after the initial dose, subsequent injections being tolerated until the dose of six to 800,000,000 was reached. When this point of intolerance was reached, the interim between injections was lengthened from five to ten days, and the dose relatively increased so that ultimately one to two billion organisms were administered. Some patients received even larger doses.

In many instances the effect of vaccine therapy was immediate and striking. We have seen patients whose stench was so pronounced that to be in the same room with them was intolerable, lose their odor after one injection so that it could be detected only in a nose to nose examination. Disappearance or lessening of odor was the most gratifying result of this method of treatment and was effected to a marked degree in almost all instances. Likewise there was a rapid reduction of the crusting. In several cases the disease was absolutely cured—with a return of the mucous membrane to normal, no recurrence of crusts or odor, and negative bacteriological findings. The most disappointing feature of treatment lies in the tendency to relapse after it is discontinued. Many patients are apparently well or with slight crusting as long as they receive vaccine. The patients, though, enjoy such marked relief from their unfortunate affliction that they willingly submit to the inconvenience of a weekly injection. We feel that the vaccine equals in efficiency any specific vaccine, yet shares in the shortcomings of vaccine therapy in general.

COMMENT.

Upon a clinical basis, the hypothesis has been frequently suggested that the origin of ozena in man can be traced to contact with dogs. Our studies have not been influenced by this assumption, and Bacillus bronchisepticus, the etiological organism of canine distemper, was selected by us merely on account of it being the best bacterial comparative with which we were familiar. The trend of our investigation has led us to the belief that Bacillus bronchisepticus and the coccobacillus of ozena are intimately related. Their protein structure is identical. Future investigation will determine whether or not the organism of distemper in dogs when implanted upon the nasal mucous membrane of man, undergoes certain biological changes due to the changes in its environment. For the time being we shall consider the organisms as distinct entities.

We are inclined to group the ozena coccobacillus with the colon typhoid group, although it has certain characteristics of the hemorrhagic septicemia group. Bacillus bronchisepticus is classed with the latter group and the similarity of the coccobacillus of Perez makes its classification with it advisable. We have suggested that the name of coccobacillus fœtidus ozœnæ of Perez be changed to that of Bacillus rhinosepticus, and the organism will be so designated by us in the future.

The consideration of the etiology of ozena cannot be dismissed without some allusion to the Abels bacillus and other organisms of the Friedlander group. In our earlier studies we were inclined to consider these organisms as being coetiological and that certain cases of clinical ozena were a result of Friedlander group infection. This assumption pre-

cluded a more thorough search for the ozena coccobacillus in our earlier cases when the Abels or allied organisms were found with negative Perez findings. As the work progressed we could isolate the coccobacillus in all cases of clinical ozena regardless of the presence of organisms of the Friedlander group. This, though, may be very tedious and bacterial investigation may not be successful until after the taking of many cultures. We have found that the injection of coccobacillus vaccines in such cases enhanced the isolation. We are inclined today to dismiss entirely the Abels and other Friedlander bacilli as etiological factors in clinical ozena and believe that they are merely saprophytic.

CONCLUSIONS.

Certain characteristics of Coccobacillus fœtidus ozœnæ (Perez) have been heretofore described erroneously, in that the organism is motile, frequently ferments certain carbohydrates, and may produce acid.

Coccobacillus fœtidus ozœnæ is the bacterial factor in the etiology of true clinical ozena.

The Abels and other organisms of the Friedlander group play no part in the etiology of clinical ozena and are purely saprophytic.

The coccobacillus of ozena is made up of many subvarieties or strains.

Coccobacillus fœtidus ozœnæ and Bacillus bronchisepticus, the specific organism of canine distemper, are strikingly similar organisms.

Bacillus bronchisepticus and the coccobacillus of ozena should be grouped together.

A change in the name of the organism of ozena from Coccobacillus fœtidus ozœnæ to Bacillus rhinosepticus is proposed.

Vaccine therapy is the most promising of all methods in the treatment of fetid ozena yet suggested. Its value and limitations are similar to those of vaccine therapy in general in combating chronic local infections.

MALINGERING.

By Paul E. Bowers, M. S., M. D.,
Michigan City, Ind.,
Medical Superintendent, Indiana State Prison Hospital and Indiana Hospital for Insane Criminals.

The prison surgeon is beset with many problems in his work, but none is more difficult or more frequent than the vexed and never ending question of malingering. Medical officers of the army and navy also have to contend with pretended illnesses of the soldiers and sailors who would shirk their duty, but to very much less extent than the medical officer of a penal institution.

Every evil seems to have its compensation. Therefore, beside being extremely annoying and a potential source of trouble, malingering has its interesting side. It taxes the physician's ingenuity, his judgment, and his skill in differential diagnosis. The physician who has never had experience in dealing with large numbers of men as in the army, navy, or State services, would find himself seriously handicapped in taking charge of the medical work of a penal institution because of the large number of malingerers that are to be found in prisons and reformatories.

The prison surgeon, to be successful in his work, must be endowed with an abundant stock of common sense, broad views, and knowledge of human nature, a kindly disposition supplemented by skill in diagnosis. If he comes to regard the majority of prisoners as malingerers, he will do a vast amount of harm, for he may overlook the illness of a convict. On the other hand, if he regards every prisoner who applies to him for relief as ill, he will be much imposed upon, and the discipline and work of the institution will suffer. It has always been my policy to allow a dozen undeserving prisoners to pass as sick than to allow one deserving of treatment to go without attention. The possibility of making a mistake in diagnosis must always be kept in mind. The question at once arises: What are the causes of malingering in prison? There are several, and among them the most important is the desire to escape work, a chance to change occupation, a visit to the prison hospital, and to secure transfer from prison to insane hospitals where the chances for escape are better, and where life is less active and devoid of strict discipline.

The prisoners practise the art of malingering in three ways: First, by feigning insanity; secondly, by pretending physical sicknesses and disabilities, and, thirdly, by the self infliction of injuries and mutilations of the body, which, while not technically malingering, amounts to the same for all intents and purposes.

The practice of feigning insanity is as old as history itself. It is recorded by Homer, that Ulysses feigned insanity to avoid going to the Trojan war; he plowed the sand of the seashore and sowed salt in the furrows instead of grain, but like the usual pretender, he overdid the matter, and his sanity dodge was promptly discovered. King David, remembering the insanity of Saul, feigned madness when he "was sore afraid of Achish, king of Gath. And he changed his behavior before them and feigned himself mad in their hands and scrabbled on the doors of the gate and let his spittle fall down upon his beard." (I, *Samuel*, xxi, 13.)

Since many insane are to be found in all prison populations, the criminal simulator of insanity has a pretty fair advantage or opportunity to study at close range the behavior of the mentally unbalanced. My personal experience has led me to believe that most frequently the forms of insanity the malingerer attempts to imitate are the acute maniacal states which are probably the easiest. The prisoner assumes an apparent state of excitement, he is restless, talkative, yells, screams, tears his clothing, makes wild gestures, and keeps up a constant rehearsal of silly, extravagant behavior when he believes he is under observation.

A condition or state of dementia is probably next most frequently essayed. The prisoner pretends to be disoriented, stupid, forgetful, childish in his manner, silly and puerile in his judgments; he disregards the rules of the institution with apparent indifference to consequences. Melancholic states are often pretended, but this is probably the poorest attempt a malingerer can make, for remorse, introspection, self analysis, sorrow, and self accusation are rarely seen in penal institutions. When a melancholic form of insanity is attempted, the prisoner generally pretends to be in a stupor, a state of irresponsiveness, indifferent to his environment, and neglectful of the calls of nature.

Some of these simulated states of insanity are so well carried out that the untrained are often deceived. The simulator usually overdoes his part because he generally entertains the idea that the insane are always absurd in their actions, their manners, and conversation. Their replies to interrogations are made with such studied silliness, absurdity, and systematic regularity that the careful examiner at once becomes suspicious. They seek to impress their observers with the idea of insanity whereas the real lunatic, if he has any insight into his condition, generally does the reverse. In one instance a malingerer who came under my notice put his food in his shoes and his shoes into his pockets, and emphatically insisted that such behavior was indicative of insanity.

Simulations of insanity, while presenting possibly some of the symptoms which belong to the form that is copied, are incomplete, or else additional inconsistent signs may be added which are entirely out of place. The symptoms of a terminal dementia would make an extremely poor combination with those of the manic phase of manic depressive insanity, and yet the feigner often attempts this combination.

Relatively speaking, few persons succeed in deceiving physicians who are familiar with mental disease. It is a difficult thing to portray accurately the symptoms of insanity, at least for any length of time, and many of the evidences of insanity cannot be simulated. The feigner often mixes the symptoms of more than one type of insanity which cannot possibly coexist. The alienist recognizing the difficulties he may encounter, must be exceedingly slow and careful in making decisions. A searching inquiry must be made into the family and personal history, and here we must be exceedingly careful, for the information supplied may be biased, prejudiced, and untrustworthy.

In States where the sane or seemingly insane prisoner is transferred to civil hospitals for the insane, the playing of the "crazy game" is quite prevalent, but in States where insane prisoners are transferred to hospitals for insane criminals which are especially constructed, and especially administered to prevent escapes, the insanity dodge is becoming very much less popular. At the Indiana State Prison it is now scarcely employed at all for the reason that this State has provided a special hospital for the criminal insane.

In the noncriminal classes insanity is simulated for the purposes of avoiding military services, to escape from unhappy matrimonial ties, to prevent the settlements of estates, to prevent divorce proceedings, to arouse sympathy, to avoid legal responsibilities, and for other reasons of a similar nature.

In one instance that came under my notice, a woman who had been detected in illicit intercourse feigned insanity in an effort to prevent her husband from securing divorce. She deliberately planned her efforts and pretenses. Among other things, she filed the plunger pin off the hammer of a revolver and then snapped the gun in the face of her attending physician whom she had threatened to kill. She placed the chinaware in the clothes closet, draped her husband's picture in mourning, and executed other carefully thought out deceptions. When I was called in consultation in this case, it was at once apparent to me that she was malingering. She tried to prove to the medical examiners that she was insane by telling them of the strange and erratic things that she did. In the course of the examination it was explained to her that her husband would give her $12,000 as a divorce settlement. Then she promptly lost all signs of insanity. That evening, she was observed parading the streets with one of her lovers.

Prisoners, in order to escape the daily duties that are imposed upon them, exaggerate their physical ills or disabilities, and even go so far as to employ a certain method of making themselves sick or even mutilating their bodies, and the prison surgeon must ever be on the lookout to prevent such practices.

When prisoners discover they have been detected in the violation of prison rules and discipline, and know that punishment and demerit are imminent, they often come to the prison hospital pretending illness and making most insistent claims, exhibiting a variety of apparent symptoms to prove their contentions. This practice is so common that in almost every instance where the prisoner is very demonstrative or vociferous when presented at the hospital for medical inspection and treatment, the trained medical officer knows that it is well to consult the disciplinary officer to learn if the prisoner is charged with offenses against the institutional discipline, and in about seventy-five per cent. it will be found that the convict has been so charged.

It will be well to consider separately the most common methods of malingering according to the personal experience I have had in dealing with prisoners. Not infrequently epilepsy is feigned. The simulator falls in a comfortable spot, his body is convulsed and twisted as he attempts to perform the movements of the grand mal seizure, and he froths at the mouth with the assistance of a little soap. His tongue is never bitten, and a careful inspection of the patient together with a dash of cold water is usually sufficient to detect the fraudulent character of his trouble. The use of soap, however, is not restricted to the simulation of epilepsy, for often it is taken in the form of soap pills to produce intestinal trouble, and the poor deluded prisoner often succeeds in producing a most intractable mucous diarrhea. Various other substances are used for the same purpose, the most common being toothpaste, toothpowder, pepper, tobacco juice, ear

wax, clippings of fingernails and toenails, pills made of feces, vinegar, urine, wood alcohol, paint, lime-water, antiseptic solutions, turpentine, and other available fluids.

One malingerer produced phosphorus poisoning with its attendant symptoms by secretly eating matchheads; another, to avoid certain tasks and to show his displeasure concerning the institutional rules, swallowed on three different occasions parts of his mirror, the face of his clock, and the electric light globe of his cell. Each time glass was recovered in the usual manner from this apparent human ostrich without evident harm.

Amputations of fingers and other mutilations of the body are occasionally indulged in by the psychopathic prisoner. In one instance the convict made the request that he be taken out of the institutional butcher shop; when he was informed that his wish could not be granted, he became very irritable and on his return to work chopped off several fingers with a meat cleaver. This same process was repeated by a prisoner in the chair shop, who cut his fingers off with a buzz saw. Prisoners have burned themselves with fire, alkalies, and acids to escape work. "Putting on the bug" is produced by placing small poultices of lime on the body long enough to bring about inflammation; after several applications discharging ulcers are produced, and several of these "bugs" soon render the offender unable to work.

I have noticed peculiar swellings of the limbs in the morning sick lines unattended by constitutional symptoms. Being suspicious of their origin, I set to work to investigate the cause, and in the course of time discovered that a sock or piece of wet cloth was drawn over the limb, hand, or ankle, which was then pounded until it was reddened and swollen, although evidences of traumatism were not produced.

Feigning blindness is not a rare practice, but the usual tests for this condition are sufficient to discover the subterfuge. It is well known among some of the criminal fraternity that the instillation of an atropine solution into the eyes will produce temporary blindness. On several occasions I have heard some of the light fingered gentry boast of the manner in which they escaped punishment by employing this drug in jail while awaiting trial, for their lawyers would make the successful plea that a blind man could not pick a lock or pockets.

Prisoners have produced the oral symptoms of septic sore throat by long continued sucking of pieces of brass, which produced grayish white ulcers in the mouth and throat; this manner of deception was so carefully planned and carried out in one institution that a quarantine was established. Belladonna has been employed to produce dryness of the throat and redness of the skin; belladonna plasters have been boiled to obtain the drug.

In some instances I have known pieces of wire to be inserted into the urethra to produce hemorrhage, also into the rectum. In one instance a glass stopper was used, but in the manipulation it got beyond the control of the pervert and slipped so high up into the rectum that an anesthetic was required to remove it. Not seldom the gums are picked to produce bleeding and simulate hemorrhage from the stomach and lungs. The manners of producing these deceptions, and the methods which are employed are as numerous as the circumstances, ingenuity, and means at hand permit.

In conclusion, it is well to say that the malingerer is generally a psychopath, who resorts to simulation and often produces physical diseases and disabilities to enable him to escape the unpleasant or painful situation in which he may find himself.

It is a mistake to believe that every malingerer is fully responsible for his acts, for it is well known that the frankly insane are given to deceptions of this nature, and since this is the case we should be extremely careful in our diagnosis.

SYPHILITIC AND PARASYPHILITIC AFFECTIONS OF THE URINARY BLADDER.

By A. Strachstein, M. D.,
New York,
Clinical Instructor and Chief of Clinic, Department of Urology, Medical College, Cornell University; Attending Genito-urinary Surgeon, Har Moriah Hospital.

(From the Department of Urology, Cornell Clinic.)

Syphilitic lesions of the bladder are not common; Paul Asch (1), in twelve years, has been able to observe only three cases. There was a belief among many authorities that the urinary bladder escaped the invasion of lues. Guyon (1) states that it is generally accepted, and rightfully so, that the urinary tract escapes luetic invasion; Morris (2) states that exemption of a hollow viscus from gummatous deposits is a truism of syphilology.

Among the many well known textbooks on urology some allude to the subject very briefly, while others do not mention it at all. Casper (3) in his *Lehrbuch für Urologie* states that he dare not say whether syphilitic ulcerations of the bladder exist because he, as well as many other cystoscopists, has never had occasion to observe any. He does not see any reason, however, why gumma formation, with breaking down of same causing ulcerations, could not exist in the bladder.

Scholtz (4) finds that in rare cases the bladder is invaded by gummatous growths secondary to rectal involvement. The symptoms, he further states, are obscure and do not differ from those of chronic cystitis and of tumor of the bladder. Finger (5) states that luetic ulcerations of the bladder are unknown, except in a very small number of cases. Chetwood (6) finds it to be a very rare condition and recognizable by circumscribed areas of inflammatory infiltration in the interior of the bladder, accompanied by a positive Wassermann. Virchow (7), however, in 1859, recognized the fact that syphilis does attack the urinary tract. He states that luetic ulcerations of the urethra are found similar to ulcerations and scar formation in the larynx. He described the findings of an autopsy in a woman of eighty years, in whom luetic ulcerations extended from the posterior urethra well into the bladder.

Matzenauer (8) was the first to demonstrate cystoscopically a gumma in the bladder. The patient was a girl who had acquired syphilis four years prior to the formation of the gumma. MacGowan (14) reported a case of a man who suffered from

bladder disturbances eight years after the initial lesion. The symptoms consisted of greatly increased frequency of urination, severe pain over region of bladder, and finally development of incomplete retention, which was not influenced by the usual medications. The bladder showed a large ragged ulcer which had evidently resulted from the merging of a group of ulcers. A von Engelmann (9) described three cases of syphilis of the bladder, one of which is very similar to a case in our own experience. He found multiple incrustated ulcerations with a general diffuse cystitis. Mixed treatment cured all three cases, in some leaving visible scar formation.

PARASYPHILITIC AFFECTIONS OF THE BLADDER.

To this group belong the affections of the bladder which, while they may show no luetic lesion in the bladder proper, are primarily due to lues of the central nervous system. The most prominent diseases belonging to this group are general paresis, syphilitic spinal paralysis—described by Erb (10), and, most important of all, tabes dorsalis. The tabetic bladder is of particular importance because it is found not only in fully developed cases of locomotor ataxia, but is frequently the first complaint for which the patient will seek relief—as was true in the case we describe. In a case reported by Paul Asch (1), the bladder symptoms preceded the other classical tabetic signs by ten years. The history of our own case is as follows:

CASE. W. R., fifty-three years old, born in Scotland, a mason; admitted to the clinic March 28, 1916. Personal history: Married, had three grown up healthy children, wife never aborted. Thirty-five years ago had gonorrhea, at which time he also had a sore on penis, which was treated locally and never received specific treatment. Present history dates back to one month ago, when patient noticed that he had partially lost control of his bladder so that he frequently had incontinence, especially at night; urine had an ammoniacal odor; had never noticed blood in his urine. Physical examination showed knee reflexes absent, moderate Romberg, also moderate Argyll Robertson pupil. No ataxic gait. Felt strong in both lower extremities. Prostate by rectum not enlarged. Cystoscopic examination showed no stricture. Urine cloudy, bladder held two ounces of residual urine. Bladder showed severe form of chronic cystitis, with marked trabeculation, especially at base. Both ureteral openings normal.

April 4th, Wassermann reaction doubtful. Advised a provocative intravenous injection of salvarsan, but only neosalvarsan was at that time procurable, so that was injected. Subsequent Wassermann test was then negative. In spite of this he was given intramuscular injections of salicylate of mercury emulsion. His urine continued to be cloudy, and his residual urine was at times from four to six ounces with no let up in the incontinence. April 11th, complained of headache and dizziness; sent to Bellevue Hospital for lumbar puncture. April 27th, report of spinal fluid examination—direct smear negative; culture negative; Wassermann test fifteen units (3+). April 28th, in addition to the foregoing treatment he was put on increasing doses of potassium iodide, while bladder irrigations with silver nitrate were continued from the outset. May 2nd, bladder symptoms had markedly improved, but lower limbs were becoming weak, in spite of the active mixed treatment. One month later, the patient began to show ataxia, complained of dizziness, his bladder symptoms reappeared, the incontinence being most marked when he was in recumbent position, while the Romberg sign became more pronounced. July 13th, treatment continued, at times to salivation, but patient complained of paresthesia of lower extremities, and incontinence, especially at night; in his opinion he was worse than before treatment. July 15th, Wassermann reaction from blood negative.

It will be noted from the history that although the patient was under active mixed treatment, new signs appeared showing that the spinal lesion was progressing and other symptoms were being aggravated. The question now arises as to what relationship there is, if any, between the antiluetic treatment and the appearance of tabetic signs not observed prior to the treatment; also as to the relationship between latent tertiary syphilis and active mercurial treatment. The literature was consulted with the following findings:

Syme, Hughes, Bennett, and others (11), explain the true cause of tertiary syphilis in excessive administration of mercury by patients being already weakened by syphilitic dyscrasia. Lancereaux connects tertiary syphilitic affections of the central nervous system with excessive use of mercury.

A. Kussmaul (11), however, stated, in 1861: "Although I have taken much trouble to do so, I have not been able to meet with a record of a single worker in mercury who has acquired primary or secondary syphilis while he was affected with mercurialism, and no malignant form of syphilis has ever been found in persons who have long been under the influence of mercury, such as miners or smelters of that metal." Marschalko (11), after exhaustive investigations carried on in Finger's dermatological clinic at Breslau, concludes that mercurial treatment exercises a preventive action even in the tertiary stage of syphilis.

Ehlers (12) states that the statistics of Fournier, Haslund, Vagda, and others are almost unanimous that tertiary symptoms are commonest in patients who have either not been treated with mercury at all, or who have been treated insufficiently.

We are confronted with a further question—whether we shall continue treating our patient with the mixed treatment, or whether it would be harmful for such a case to be so treated, in view of the tabetic symptoms growing progressively worse while he was under this method.

The observations of Erb (13) on this very point are both interesting and authoritative. Erb thinks that a vigorous course of treatment will remove the original cause of the disease, but the degenerative processes once set in motion will continue slowly to advance even if the original cause is removed. At best we can only hope to prevent the progress of the morbid action to the unaffected nerve tracts, and must leave those already damaged to their fate.

CONCLUSIONS.

1. Syphilis may attack the urinary bladder as well as other viscera.

2. Syphilis of the bladder occurs during the tertiary period of the disease.

3. A bladder affected with syphilis will frequently show no characteristic lesion, and the diagnosis must be made in conjunction with a positive Wassermann and the ready response to antiluetic treatment.

4. A gumma in the bladder is sometimes difficult to differentiate from papilloma.

5. Specific treatment is harmless and of decided benefit in many parasyphilitic affections of the bladder.

6. A certain number of cases remain in which no visible improvement occurs in spite of energetic treatment.

EPIDEMIC GASTROENTERITIS, INFANTILE PARALYSIS, AND INFLUENZA.

By Bernard Frankel, M. D.,
New York.

During the current year I have had under treatment in private practice, as well as at my stomach clinic in the outpatient department of the New York Hospital, numerous cases of gastrointestinal disorders, which although generally diagnosed and treated as cases of ordinary indigestion, I have found to be distinctly epidemic in character, and to a great extent contagious. I have observed similar cases, mostly during previous epidemics of influenza, for some years past, but find them especially prevalent since the grippe epidemic of last winter and early spring. Since then they have been increasing in numbers throughout the summer and fall; this epidemic of gastroenteritis running side by side with that of infantile paralysis. The gastrointestinal disturbances in some instances usher in the paralysis in children, while in others they attack various members of the family, where infantile paralysis occurs.

The attack may involve the stomach and intestines either separately or together. The onset, sometimes preceded by catarrhal symptoms, is usually marked by anorexia, nausea, and vomiting, which at times is persistent, and very hard to overcome.

The bowels, sometimes constipated at first, usually become loose, the movement large, watery, and accompanied by griping, and at times vomiting and a feeling of faintness. On the contrary, the stools may be small, very frequent, accompanied by tenesmus, and contain mucus, and even blood, thus resembling closely the stools of acute enterocolitis or even of dysentery. But instead of amebas they are often found to contain streptococci.

The subsequent course, although usually mild, with only a slight elevation of temperature and a tendency to recovery within a couple of weeks, especially in adults, is subject to wide fluctuations, and at times to severe unaccountable exacerbations, especially in children. During these exacerbations there is usually a marked elevation of temperature with aggravation of all the symptoms, followed sometimes in children by the onset of paralysis, and even in adults by abdominal distention, pain, and tenderness on pressure; at times accompanied by jaundice, and occasionally even leading to a fatal termination, as illustrated by the following cases.

Case I. Mrs. H——l, twenty-four years old, of Rockaway Beach, N. Y., previously in good health, was suddenly taken ill with nausea, persistent vomiting, and obstinate diarrhea. When I first saw her, about a week later, she was jaundiced, her abdomen was distended and tender on pressure, but neither the liver nor the spleen were palpable. Her temperature was 102° F., pulse 110, respirations 28; the urine was scanty, high colored, and contained some albumin, but no casts. I prescribed opium and belladonna rectal suppositories, large doses of bismuth with codeine by mouth, and a very light diet. This was followed by marked improvement during the next few days, until suddenly one night there was an exacerbation of her symptoms, and the relatives, becoming alarmed, had her removed to a hospital. There she had a pyemic temperature, her jaundice became deeper, the abdomen more distended; she then became delirious and later coma was followed by death in less than a week after her admission. The consultants were greatly puzzled by the case and, finding their tentative diagnosis unsatisfactory, were very anxious to have an autopsy, but this was refused.

Soon afterward the mother, who nursed the patient in her illness, had an attack of nausea, vomiting, and diarrhea with griping; after her the orphans left by the dead woman, and later also a brother who boarded there—all showed similar symptoms, although not so severe. Opium and belladonna suppositories and bismuth with codeine by the mouth were given, and they all recovered within a few weeks.

During the height of the epidemic of influenza of last winter and early spring a series of very severe cases of gastroenteritis, many of which terminated fatally, were reported from Chicago—if I remember rightly—or its vicinity. Some of the physicians thought them to be cases of ptomaine poisoning. Poisonous candy was suspected as a cause; but no satisfactory diagnosis was made, although one physician found streptococci in the stools. Yet from the descriptions of these cases I had no doubt at the time that they were cases of severe gastroenteritis of influenza.

Case II. Last August, in Belmar, N. J., a five year old child of a family from New York city, who spent the summer there, was taken sick with a "cold," which seemed to have improved greatly in a couple of days, when suddenly there was a rise of temperature, nausea, vomiting, and diarrhea, with a very heavily coated tongue and offensive breath. These symptoms continued, in spite of treatment by prominent New York specialists, for the next couple of days, when paralysis developed and rapidly ascended, causing death by respiratory failure.

In some cases there is a marked nervous irritability of the stomach, manifesting itself by anorexia, nausea, and very obstinate vomiting. This is probably due to the deleterious effect of the toxines of influenza on the nerves of the stomach as well as upon the general nervous system. The following cases may serve as illustrations:

Case III. In the fall of 1904 I was called to see Mrs. L. L., forty-five years old, the wife of a New York attorney. She was in good health until a few days previously, when an attack of influenza set in, accompanied by persistent vomiting. This vomiting at first followed only the ingestion of food or drink, but soon became almost continuous, and was accompanied by distressing retching, so that even gastric sedatives, like codeine and bismuth, were not retained. Having ruled out organic diseases of the stomach as the possible cause of the vomiting, I came to the conclusion that I had to deal here with a gastric neurosis caused by the influenza; finding lavage ineffective and medication per os impossible, I prescribed very small, but high rectal enemata of potassium bromide grains xl, tincture of valerian ʒi, mixture of asafetida up to half an ounce, in one third of a cup of warm milk, to be re-

tained for many hours. The effect was almost magical, thus furnishing a therapeutic confirmation of my diagnosis, the vomiting was rapidly controlled, and the patient made a good recovery.

She continued in good health subsequently for over two years, and gained a good deal of weight, until in the spring of 1907 another attack of grippe set in, again accompanied by vomiting. I was away on a vacation, and another physician was called. Finding it impossible to stop the vomiting, he consulted one of our most prominent gastrologists and the latter, suspecting carcinoma ventriculi, had the patient transferred to the hospital he was visiting, where he kept her under his personal care and observation. There a thorough examination enabled him, as he admitted later, to exclude carcinoma or other organic troubles, but the patient continued vomiting and retching and finally died from exhaustion in about four weeks. No bromide, valerian, nor asafetid enemata were used during her second attack.

Case IV. Mrs. T., who stopped with my family at Bradley Beach, N. J., manifested, last July, an attack of grippe with catarrhal symptoms, bronchitis, anorexia, nausea, and diarrhea; a few days later, my wife complained of nausea, anorexia, and diarrhea with griping, which lasted for about three weeks. During the same time my three and a half year old little girl was suddenly attacked by nausea, retching, and vomiting, even on an empty stomach; all medication proving ineffective, I had recourse to high rectal enemata of potassium bromide in a very small amount of warm milk to facilitate their long retention and absorption, and succeeded in stopping all symptoms, the child recovering rapidly. Soon after, I also lost my appetite, felt nauseated, and had a diarrhea with griping, which symptoms with remissions and exacerbations lasted over four weeks, during which time other members of my family, who remained at our home in Elmhurst, L. I., where I frequently went, also suffered from similar symptoms, only two of the whole family escaping the contagion.

In distinct contrast to this epidemic of gastroenteritis, which has so far been overlooked completely, the epidemic of infantile paralysis, which ran side by side with it, received the almost undivided attention of some of our noted medical men, and so far has baffled their untiring efforts. Despite endless research work and close observation in hospitals of thousands of cases in the various stages of the disease, we are as yet completely in the dark as to the true character, etiology, early diagnosis, and treatment of infantile paralysis.

The reason why our most advanced and usually successful methods of study of infectious diseases have so signally failed us in the case of infantile paralysis lies, I think, in the fact that our reasoning started from false premises, and thus putting us on the wrong track, inevitably led to false conclusions.

To begin with, infantile paralysis has no clinical or etiological entity. Like the glomerular nephritis of scarlatina, it is only a complication of an infectious disease, which may or may not follow it, and may during some epidemics, become especially prevalent, attacking then by preference the much more vulnerable nervous system of children. This view of the character of infantile paralysis is borne out by the following facts:

1. The epidemic of infantile paralysis came in the wake of the grippe epidemic of last spring, and ran parallel with the gastrointestinal variety of that disease.

2. In some instances the contagion of infantile paralysis could be traced directly to influenza, especially of the gastrointestinal type, in another member of the same family.

3. The onset and early symptoms of infantile paralysis are identical with those of the corresponding type of influenza, from which it cannot be differentiated in the preparalytic stage. As a matter of fact, at the height of the epidemic cautious physicians classed many cases of influenza as suspected poliomyelitis, and, if no paralysis manifested itself, called them abortive cases.

4. The wide fluctuations, frequent relapses, and at times violent exacerbations, which present one of the most characteristic features of influenza are also common to epidemics of gastroenteritis, and to the preparalytic stage of acute anterior poliomyelitis.

I hope by this communication to draw the attention of my colleagues to the prevalence of these epidemic gastrointestinal disorders, especially in their milder forms, sometimes with anorexia, nausea, and lassitude as their only symptoms for weeks; to the close relation existing between them, as well as between infantile paralysis and influenza, and to the advisability, therefore, of applying to these cases the principles of prophylaxis and treatment employed in influenza generally.

In conclusion, I wish to point out also that, since inoculation with the Pfeiffer bacilli has failed to produce influenza in animals, while streptococci are as a rule found much more frequently than the former in severe forms of influenza, especially those complicated by angina, enteritis, pneumonia, and other respiratory disorders,[1] and of late also in infantile paralysis (by Rosenow and his coworkers)—it seems to me well worth the trouble to investigate more thoroughly the causative relation of streptococci, not only to the secondary infections of influenza, but to its primary onset as well.

1234 Madison Avenue.

Prognosis in Pellagra.—J. F. Siler, P. E. Garrison, and W. J. MacNeal (*Archives of Internal Medicine*, September, 1916) discuss the subsequent history of pellagrins who have survived the initial attack, as revealed in their observations in Spartanburg county, South Carolina. The number of cases of recurrent attacks of pellagra recorded was 1,053, of which 130, or 12.3 per cent., were fatal within a year after the recurrence. The number of cases of freedom from recurrence for a like period was 617. The ratio of nonrecurrence to recurrence was thus about as four is to seven. In the later years of the disease the prognosis grows more favorable for recovery from an existing attack, but less favorable as to escape from recurrence in the subsequent year. The disease thus becomes, with time, more firmly established as a chronic condition, but less acutely malignant. A year without recurrence is a favorable omen, subsequent recurrence being less likely and less fatal. It is not uncommon, however, to witness recurrence after several years of freedom from the disease. To say when a patient has definitely recovered is impossible. Where recurrence is escaped for one or more years the disease had best be considered merely arrested or inactive, much as in tuberculosis or syphilis.

Our Readers' Monthly Prize Discussions

Twenty-Five Dollars Is Awarded for the Most Satisfactory Paper

All persons, whether subscribers or not, are invited to compete for the prize of $25 offered for the reply deemed best by the editors to the following questions:

CLXXVI.—How do you treat Colles's fracture of the radius? (Closed.)

CLXXVII.—How do you treat delirium tremens? (Answers due not later than December 15th.)

CLXXVIII.—How do you treat acne vulgaris? (Answers due not later than January 15, 1917.)

The award will be based solely on the value of the information contained in the answer. No importance will be attached to literary style. Answers should preferably contain not more than six hundred words, and should be written on one side of the paper only. All papers submitted become the property of the JOURNAL, and should bear the full name and address of the author for publication. The prize will not be awarded to the same person more than once within a year.

The prize of $25 for the best answer to Question CLXXV has been awarded to Dr. S. Bernard Rosenzweig, of New York city, whose paper appears below.

PRIZE QUESTION NO. CLXXV.
THE TREATMENT OF FURUNCULOSIS.

By S. BERNARD ROSENZWEIG, M. D.,
New York.

A clear conception of the underlying causes of furunculosis is a *sine qua non* of its proper treatment, without which a comparatively simple surgical condition may develop into a long siege of pain and discomfort, multiple incisions and dressings, and nasty scars. Briefly, the causes are local and general. Remove one or a combination of them, and the patient is happily restored to his daily functions.

A. LOCAL CAUSES:

I. Skin:
- 1. Hairs: *a.* Ingrowing hairs. *b.* Tortuous hair follicles.
- 2. Sebaceous glands: *a.* Oily skin. *b.* Comedones. *c.* Acne.
- 3. Sweat glands. Profuse perspiration with maceration of skin—as in axillæ.

II. Clothing: Irritation from collars and seams of clothing.

III. Autoinoculation:
- *a.* Improper dressing, as poultices, salves, homemade plasters, etc, make ideal conditions for growth and multiplication of microorganisms (heat and maceration of skin).
- *b.* Fingernails, pus carried by scratching and squeezing.
- *c.* Infected clothing; dressings not changed sufficiently often.

IV. Microorganisms: Active staphylococcus, streptococcus; less commonly colon bacillus; and rarely pyocyaneus.

B. GENERAL CAUSES:

I. Blood; conditions favorable to growth of bacteria (as glycosuria).

II. Blood; lack of antibodies:
- *a.* "Run down" conditions.
- *b.* Anemia.
- *c.* Constitutional diatheses.
- *d.* Intercurrent illness.

At a glance, this table will be helpful in solving the etiology of any given case. Generally, one particular factor will be prominent; most commonly, however, a contributing cause can be discovered.

TREATMENT.

Abortive. When seen early, tincture of iodine painted over the reddened areas, with epilation of infected follicles, and a wet fifty per cent. alcohol dressing, may suffice to abort the condition. If there is a small, superficial collection of pus, the old fashioned match stick with phenol is often useful.

Active treatment requires a free crucial incision through the entire indurated area to allow drainage and to relieve tension. In large boils, it may be necessary to undercut the flaps. A wick of gauze, impregnated with dilute mercurial ointment, will prevent premature superficial closure, and permit drainage. The dressing should be plain gauze and kept moistened with fifty per cent. alcohol. The evaporation of the alcohol is cooling; it is bactericidal and toughens the skin, assisting nature to close atria which would otherwise become infected. I know of no better local application than fifty per cent. alcohol, both for the immediate comfort of the patient, and his early relief from the furunculosis. Alcohol may be continued throughout the entire treatment, or later, balsam of Peru (without oil) may be substituted.

The general treatment should be begun at once. One phase is the treatment of constitutional disturbances and the institution of careful hygiene. A nutritious diet, with moderate restriction of carbohydrates is advisable, even without the presence of glucose in the urine. Constipation should be relieved without delay. The most important procedure is the manufacture of an autogenous vaccine. Many men concede that in long drawn out cases, this offers the only hope of cure. Rather than wait for chronicity, I always inoculate a culture tube for diagnosis on the appearance of the first boil. If a second one develops, the laboratory is prepared to turn out the vaccine in record time. Ten million dead microorganisms are injected at the initial dose, and subsequent doses are injected, at first at intervals of five days, later four days. The injection is made subcutaneously, the dose increasing by ten million until fifty million are given, after which the increase is twenty-five million each time. The treatment is painless and without untoward sequelæ. The actual bacterial count in each dose varies with different men. The opsonic index is rarely employed to determine the negative phase; a sufficient interval is maintained between the injections. Stock vaccines have given good results in the hands of many surgeons. A mixed culture of staphylococcus, streptococcus, and colon bacilli should be used. The fact that larger doses must be given, and that the patient is required to manufacture antibodies against unoffending germs should favor the use of the autogenous vaccine, the manufacture of which is simple and may be entrusted to any competent bacteriologist.

Dr. J. Otis Carrington, of Malden, Mass., writes:

In treating furunculosis, a rigid search must be conducted to ascertain the cause of lowered vitality,

as it is this condition—impaired vitality—which predisposes to, and causes boils by lowering resistance and allowing the ingress of the various microorganisms responsible for the condition.

Examine the urine for sugar or albumin, and, if present, treat the diabetes or nephritis. Frequently boils are a concomitant in these diseases and occasionally in septicemia. Nor are they infrequent in persons run down from anemia, digestive disturbances, constipation, absorption of toxins from the alimentary tract, improper or insufficient food, alcoholism, convalescence from severe illness, e. g., typhoid fever or smallpox, and in those exposed to the noxious gases of bad drains. In short, any debilitating influence, when ascertained, must be treated by suitable measures, dietetic, medicinal, and hygienic.

TREATMENT.

For convenience, treatment may be divided into constitutional, local, and vaccine.

Constitutional treatment. Abundance of fresh air, free evacuation of the bowels—by medication if necessary—and frequent bathing should be insisted upon throughout treatment. The debilitated condition calls for tonic medication, such as combinations of iron, quinine, and strychnine, or iron and arsenic; also for generous diet of milk, eggs, cream, and fresh meats. Not infrequently a change of diet, climate, and habits is very serviceable in prolonged furunculosis. Fresh brewer's yeast, one to two drams in water, three times a day before meals, is good throughout the disease, as is nuclein solution in one dram doses in water, between meals and at bedtime. If boils are already present, give calcium sulphide in one tenth grain doses every four to five hours; it hastens the boils to mature and prevents the formation of new ones, but is useless in the furunculosis of diabetes. The action is probably due to the excretion of sulphur in the sweat which in passing through the skin acts as an antiseptic, and to its mild laxative effect.

Local treatment. The objects of local treatment are to reduce the inflammatory process, to allow for the free exit of pus, and to prevent the infection of neighboring hair follicles, sebaceous glands, or sweat glands. The surface of the boils and skin should be kept thoroughly clean by the frequent use of hot water and tincture of green soap, applied twice a day, or by a simple antiseptic solution, such as alcohol, or corrosive sublimate one in 5,000.

Boils may frequently be aborted when they first start by painting with collodion containing a five per cent. solution of iodoform every hour until a heavy contractile coating is formed, but leaving the centre uncovered. If pus forms under this, it may be absorbed; but if not, open aseptically and dress. Local application of extract of opium or belladonna relieves pain and tends to decrease inflammation. Injection of three drops of five per cent. phenol also helps.

In the early stages of induration, when no signs of softening are present, apply fomentations of hot boric acid compresses, or carbolized epsom salt compresses, changed frequently and continued persistently until softening takes place and signs of fluctuation appear. Then incise and allow pus to flow out; irrigate with one in thirty phenol. The boils should not be opened in the hard stage nor squeezed after they are opened. Infection of the neighboring integument from discharge should be prevented by painting with tincture of iodine for a distance of one inch around the boil.

Lesions at the nape of the neck are particularly troublesome owing to continuous friction from the collar band. Remove all friction by wearing soft silk collars. Treat locally with compresses of hot boric acid, or hot carbolized epsom salt and a generous application of the following:

℞ Resorcinolis, ...gr. xx;
Acidi borici, ...℥iss;
Alcoholis, ...℥i;
Aquæ distillatæ, ...ad ℥v.
M. Sig. Locally, three or four times a day.

Follow this with a thick layer of boric acid and a light dressing for a day or so. When the lesions are larger and maturing, apply ichthyol, twenty-five per cent.; incise, when necessary, with aseptic precautions; and treat constitutionally.

Vaccine treatment. This is more successful in acute cases as an adjunct to local and constitutional treatment than in chronic cases. Start with a subcutaneous injection of 100 millions of staphylococci and increase by 100 millions each week until 500 millions are reached. Autogenous vaccines, too, are worthy of a careful trial and often give gratifying results.

Dr. Charles H. Nammack, of New York, observes:

Although we have it on good authority that the affliction of furunculosis has been known since ancient days, the fundamental features of its treatment have not changed greatly. The salient factors in the production of this disease are a subject with lowered vitality, a point of least resistance in the skin, the invasion of pyogenic organisms, and the formation of a localized abscess.

The treatment is prophylactic, local, and general. The prophylaxis is simple, but, unfortunately, not always effective for the reason that the invading organisms are ubiquitous, numerous, and hardy. Any person who discovers that he is prone to boils in any particular part of the body should concentrate his attention there. Absolute cleanliness is essential and clothes should be worn that do not bind or irritate, as high tight collars so often do the neck. Superfluous hair should be removed, frequently if necessary, and the region should be bathed daily with green soap and warm water followed by a sponging with ninety-five per cent. alcohol, which seems to be particularly effective against the skin inhabiting organisms.

The local treatment is entirely of a surgical nature. While waiting for the evidence of pus formation or "coming to a head," as the lay expression has it, it is frequently desirable to use applications to relieve the pain and heat, in which case wet dressings in the form of aluminum acetate saturated solution or alcohol are excellent. If it is deemed advisable to hasten the process, a poulticing dressing such as ten per cent. ichthyol may be used.

When the pus has formed, the sooner it is evacu-

ated, the more quickly will the boil heal. With a sharp scalpel, an incision is made at right angles to the grain of the skin over the point of maximum fluctuation, and the contents of the abscess are allowed to escape and may even be gently expressed. The incision is made in the way described in order to keep the edges of the wound apart and insure free drainage. Following the incision, a cotton swab on a toothpick is dipped in pure carbolic acid and is plunged, not without considerable pain, into the depths of the abscess and then rotated. The dressing consists of sterile gauze and boric ointment. Boils so treated will usually be found to be entirely healed in from thirty-six to forty-eight hours. It is also possible to abort the formation of pus by employing this method of treatment before pus has formed.

As furunculosis usually occurs in patients whose vitality has been lowered by some other condition, such as certain of the acute febrile diseases, the general treatment is directed toward the primary condition. If it occurs in a patient who is otherwise considered to be well, it is the duty of his physician to look for some underlying factor. Uranalysis, examination of the blood for anemia and Wassermann reaction as well as careful inquiry into general hygiene, appetite, digestion, and elimination, may furnish the key to the situation. The general treatment, therefore, resolves itself into measures which are aimed at general upbuilding, and consists of baths, outdoor exercise, the correction of errors of diet and elimination, and tonics when they are indicated.

The commonest organism found on culture from furuncles is the staphylococcus, which is not always the slightly virulent pyogenic organism that we have come to regard it, being prone to the production of secondary bone lesions. On treating cases of furunculosis, especially in young children, we should, therefore, be on the alert for a complicating osteomyelitis, usually ushered in by a chill, sudden rise of temperature, and severe bone pain. The failure to recognize this condition has been referred to as the tragedy of medical diagnosis in children. The treatment is prompt surgical intervention.

In cases which show a tendency to become chronic or to have relapses or recurrences, we have a powerful weapon in the form of autogenous vaccines. There is no disease that is better adapted to vaccine therapy than this. The condition is so localized and walled off from the general circulation that it fails to stimulate the subject to the formation of antibodies capable of resisting the invading organisms. Make cultures from the lesions, determine the organisms present, and then make autogenous vaccines. The vaccine may be given once a week by deep subcutaneous injection. By this means passive immunity to this disease can be rapidly developed, which will result in its more rapid cure, when used in conjunction with the measures already described, and will protect the patient against further attacks. Using a vaccine whose strength was one billion organisms to the c. c., we could start with a dose of 250 million and increase each week, doubling the dose until two billion was reached. This makes the course of vaccine consist of only four doses.

Dr. Louis Neuwelt, of New York, remarks:

Furuncles are due to the infection of the hair follicles by staphylococci. While infection is usually local, it often becomes general, resulting in successive crops of boils; this condition is called furunculosis.

General treatment. The patient's general condition and the urine should always be examined with the purpose of finding a latent diabetes or nephritis. The patient's resistance and vitality of the skin may be lowered by specific fevers, anemia, uremia, septicemia, a general run down condition, or by skin diseases, such as eczema, prurigo, lichen, or scabies. Frequently no disorder of the general health can be discovered. If any of the previously mentioned diseases are found, appropriate treatment should be instituted.

It is important at the outset to induce free daily bowel movements, to regulate or change the diet so as to prevent gastrointestinal indigestion, to give general advice as to hygiene, and tonic treatment in the form of iron, quinine, and strychnine.

Good results often follow the taking of one third of an ordinary compressed Fleischmann yeast cake, dissolved in a glass of water, twice daily.

Local treatment. "Hands off" is the rule for young boils as well as older ones. By squeezing, nature's effort of walling off the infection by surrounding it with leucocytes is thwarted, and as a result, the infection spreads through the break in the wall of leucocytes. If left alone, boils sometimes resolve, which is another reason for not handling them.

Abortive treatment. The best way of aborting a furuncle is to dip a sterile toothpick into pure phenol, shake off the excess, then bore the point firmly and deeply into the centre of the furuncle and withdraw it; a white eschar forms. This procedure is practically painless, because of the anesthetic action of the phenol. Paint the boil and its surround area with tincture of iodine, and cover with dry sterile gauze, held in place with zinc oxide adhesive plaster strips.

Later stage treatment. When seen later, in the pointing stage, puncture with a red hot needle shortens the treatment. An ordinary darning needle is run through a cork for the purpose of handling it. The point is heated in an alcohol flame until red hot. The skin is gently pinched into a fold with the furuncle at its top until its centre shows a white, bloodless spot. Noting the direction in which the hair grows, the heated needle is plunged three or four mm. deep into the white spot in the direction of the hair growth. The tension and pain stop at once. Pressure is then exerted on the burned spot, and if tenderness persists, the process is repeated. Small, dry gauze (sterile) dressings are applied to prevent the spread of infection to the healthy skin.

In large sized furuncles, after puncture, apply gentle suction (which should be painless) with a Bier cup for three to five minutes, and repeat in four hours. Shave the hair for one inch around the infected area, and wash it with benzine, followed by alcohol. Gauze soaked in Wright's solution is an excellent wet dressing, made occlusive

with waxed paper or rubber tissue to retain the moisture, and secured with a bandage. The dressing should be kept constantly wet with the solution. When the sloughy core becomes loose, it is removed with forceps and the cavity is swabbed with tincture if iodine. Dry sterile gauze dressing are used until a cure results.

If an abscess forms, apply a warm alcohol poultice, one part of alcohol and four parts of warm water, on sterile gauze and made occlusive. This should be changed twice daily. Care should be taken not to irritate, rub, or scratch the adjoining skin, or to use too hot applications.

Furuncle of the external auditory canal. The canal is cleaned of cerumen, products of desquamation, discharge, or foreign bodies. A wick of gauze is inserted into the canal, nearly to the drum membrane, and filling the lumen. The furuncle is now punctured as previously described exactly in the centre. The wick is then saturated with alcohol, or with boric acid (half and half), and the patient is instructed to keep the wick constantly wet by dropping alcohol on it at frequent intervals. The physician replaces the wick daily with a fresh one until the cure results.

Vaccine therapy. In obstinate cases, vaccines should be used. As it is known that furunculosis is a staphylococcus infection, stock vaccines of staphylococcus (combined) may be used if autogenous vaccines are not available.

Whenever possible, however, the autogenous vaccine should be prepared. The primary injection of thirty million bacteria to one mil is given; the next, sixty million. the third eighty million, and the fourth on the seventh day of 100 million, allowing an interval of two days between each two injections. The proper vaccine and dose should produce some general reaction and a definite temporary increase in local symptoms. If the reaction is too severe, lengthen the intervals, or decrease the dose. There is no general rule to follow in doses, as every case is a law unto itself. Usually eight to twelve injections are necessary.

Prophylaxis. Patients who suffer with frequent recurrences of furuncles should be instructed to scrub the affected part of the body daily with a brush, using tincture of green soap and warm water, and then wash it with alcohol. The physical condition should not be neglected.

Dr. C. B. Burry, of Woonsocket, R. I., advises:

In treating furunculosis assume complete charge of both patient and boils, on their first appearance in your office. Do not allow patient to tell you that he will drop around again in a few days if the boil you have treated does not feel any better. Insist on daily visits until the case is under control. Forbid any home tampering with your dressings, and taboo germ spreading cracker or soap poultices. The patient who boasts that he suffered with boils for six months, had tried all the doctors in town without success, and was finally cured by an old woman's recipe is the fellow who promised to drop around again in a few days and failed to return because there was a mutual inclination on the part of doctor and patient to treat the boil as a joke.

Examine the urine in every case and do not let the other fellow beat you to it with the diabetic or nephritic diagnosis.

It should not be forgotten that the majority of patients need instruction as to change of food and habits of living. Vacations and alterative remedies have their place.

If suppuration is not sufficient to call for the knife, try abortive methods, making use of carbolic acid or tincture of iodine. Employ the Bier hyperemic cup in conjunction with the local applications.

Incision being imperative, give the necessary surgical treatment, remembering that a sharp knife, a little ethyl chloride, and attention to technic make more friends than the haphazard maneuvres of the cobwebbed office. The Bier hyperemic cup will prove of great assistance, as it will withdraw the products of inflammation and bring better blood to the part. The suction seems to hasten healing. Ichthyol, twenty-five per cent., will prove soothing when applied to the inflamed area and will prevent spread of infection. But in these days of drug famine it is well to recall that the hot boric acid compress is credited with similar properties.

Opinion seems divided as to the merit of calcium sulphide. In case it is dispensed, it is well to supplement it with the familiar but efficacious iron, quinine, and strychnine tonic, or some similar tonic. Remember that in stubborn cases dilute nitrohydrochloric acid has a decided alterative effect.

During the past few years the vaccines have won a leading place in the list of remedies for furunculosis. The autogenous vaccines appear to give better results, but the stock vaccines are usually satisfactory.

The yeast preparations have helped, whenever tried. Internally and externally, they appear to diminish the extent of the boil crop. Some excellent preparations of this remedy are being made by the leading drug houses.

In closing, it is desired to say an extra word of praise for the Bier hyperemic suction cup. Its use shortens the duration of the boil.

Cancer of the Cecum in a Young Adult.—Bréchot (*Presse médicale,* October 9, 1916) reports the case of a young soldier twenty-two years of age who came under observation complaining of slight digestive disturbances, vague pains in the right iliac fossa, and intermittent diarrhea. There was no paroxysmal colic, melena, or fever. Soon a mass of the size of two fists, vertically elongated, movable internally to the midline, and very firm and irregular, was noted. Without being able definitely to exclude hypertrophic ileocecal tuberculosis, Bréchot excised the ileocecal angle and ascending colon and did a laterolateral ileotransversostomy. The patient recovered and left the hospital apparently cured. The paucity of preexisting functional symptoms was explained by the specimen, which showed a round tumor not involving the appendix, fundus of the cecum, nor the ileocecal valve. The growth was an atypical epithelioma, which had extended to the ileocecal lymph glands. Enlargement of more distant glands had not been found at the operation.

WHY NOT THE DOCTOR?

When prices begin to go up, popular opinion avers that wages will be the last item to acquire the soaring tendency. Wages indeed are extremely conservative in such matters, but there is another class of payments that is even more laggard; our readers will quickly guess that the reference is to professional fees. Far from going up, the average physician finds some of his fees vanishing altogether, and almost alone in the community he has his income decreased both relatively and absolutely. This tendency was felt long before the beginning of the present European war, but undoubtedly that catastrophe has both hastened and heightened the crisis now upon us. A writer in *Commerce and Finance* for November 22d informs us that a prominent manufacturer of Boston has foretold that within three months shoes would be selling at twenty, possibly thirty dollars the pair; hides are now costing fifty-five per cent. more than on September 1st; New York cobblers have raised their prices twenty-five per cent. Potatoes are six dollars a barrel, the best eggs ninety cents a dozen, and brewers are casting about for the least objectionable way of getting a larger price for beer. Worst of all, those who feasted on turkey on Thanksgiving Day paid from forty to forty-five cents a pound for the bird, while many had to be satisfied with ducks or other unorthodox fowl.

Our ethical attitude toward fees is beautiful, and we should be the last to suggest that what is still an honorarium should become a fixed price. We think that very few of the laity comprehend this viewpoint of ours, and most of them believe that they pay us exactly what our services are worth. They lose sight of the lives we save, and the restoration to complete function of damaged members. Whether a patient entertains this view, or recognizes the peculiar nature of the fee, we feel sure that little, if any objection will be made on his part to its increase. The stagnation of fees is due simply to our own inertia and lack of team work. Even if resolutions are passed at society meetings to establish new standards, charitably inclined or weak members will stick to the old schedule. They will continue to live from hand to mouth, with too little regard for the day when a widow and family may have to provide for themselves. The automobile quickly became a necessity to the country doctor, but no rise in fees occurred, although motor car upkeep is a serious drag on a fairly good income.

We believe that this matter of fees should be taken up at once. Schedules should be proposed at society meetings, and the results should be made public in order that the laity may not be taken unawares. One dollar should become two dollars, two dollars should become three, and the wretched minimum charge of ten dollars for a confinement "without instruments" should be promptly raised to fifteen. These are mere suggestions. Why should the doctor alone try to live on an income that was none too large two score years ago, and has been virtually growing smaller every year since?

CEREBROSPINAL MENINGITIS AND POLIOMYELITIS.

Among maladies still more or less mysterious, poliomyelitis and cerebrospinal fever may be regarded as in the front rank, for of neither is anything very clearly known. Perhaps it might be more correct to say that there are many features of both diseases which require elucidation. Moreover, these affections present a number of points of similarity; their onset is somewhat similar, and their progress also is not unlike, that is, up to a certain stage, and the germs of both are found in the nose, throat, and intestinal tract.

A Medical Research Commission, in England, has

been investigating cerebrospinal fever and has handed in a report of its findings. In the *Medical Press* for October 11, 1916, Sir William Collins reviews this report and finds in it many inconsistent statements which he criticizes caustically. He points out that what the uninstructed laity wants to know is: What is the cause of this mysterious disease? Can it be cured or prevented, as has been confidently alleged, by inoculation or vaccination, and how is the disease propagated, from those who have caught it by infection or by those who have not been attacked, though they harbor the germ—the so called carriers? As he states, the evidence with respect to the vera causa of the disease is far from reassuring. We are indeed told about the "causal organism" and pontifically assured that "the evidence to the effect that cerebrospinal meningitis is due to infection by Diplococcus intracellularis meningitidis of Weichselbaum, commonly known as the meningococcus, is accepted as adequate by practically all bacteriologists." Collins is by no means convinced, however, that the bacteriologists are absolutely right, and he draws attention to many apparent fallacies in their train of reasoning. For example, a considerable number of noncontacts have been shown to harbor the germ of cerebrospinal fever and are therefore carriers. Why then do those persons who harbor the germ, although not immune, fail to suffer from the disease, and why do some of those who suffer from the disease not harbor the germ? These are, in his opinion, problems in logic which the bacteriologist may be better able to grapple with than the mathematician.

All investigators of both cerebrospinal meningitis and poliomyelitis, whether bacteriologists or clinicians, are agreed on one point, that overcrowding and lack of ventilation are powerful predisponents of the disease, and that where air space is ample and ventilation efficient neither malady is likely to spread.

Thus prevention is, in this instance as in all instances, better than cure, and with an average mortality as high as fifty per cent., the specific treatment of the disease by serums or vaccines is admitted in the report to be "generally unfavorable."

Flexner's views with regard to specific treatment of poliomyelitis are practically identical with those given in the report with respect to cerebrospinal fever, for he states, "that there is no safe method of preventive inoculation or vaccination against poliomyelitis, nor any practicable method of specific treatment. The prevention of the disease must be accomplished by general sanitary means."

Much more will have to be learned regarding these diseases ere they can be prevented or treated with great hope of success. They are still mysterious and obscure. The significant fact has been learned that sanitary measures rigidly enforced are the only safeguards against the spread of either malady, and once again is brought into prominence the dictum of John Wesley that cleanliness is next to godliness. This word of wisdom should be heeded in New York and other large cities where the diseases are prone to lie latent, and when awakened to spread far and wide.

THE FILTERABLE VIRUS.

For a generation or more we have looked upon the ordinary bacterial forms as the ultimate causes of many diseases, and the science of bacteriology has become crystallized along definite lines. But in this, as in other sciences, certain new facts have come to light which are not in harmony with established ideas. The tendency has been general to ignore these conflicting facts, but a few workers have studied them with results that bid fair greatly to modify our bacteriological concepts.

In a recent article J. G. Adami (*British Medical Journal,* October 14, 1916) discusses some of these new problems and their interpretation. He points out the firmly established position of Bacillus typhosus as the cause of typhoid fever. Killed cultures of this bacillus will cause immunity to typhoid, but no one has ever succeeded in producing the disease in man or animals with a living stock culture of the organism. Bacillus suipestifer has occupied an analogous position in the animal world. Its cultures, likewise, will not cause hog cholera, although it is always associated with that disease. Recently the true cause of hog cholera has been shown to be an ultramicroscopical, filterable virus.

Quite similar findings have been recorded in the case of an epizootic of guineapigs, in canine distemper, and probably in scarlet fever in man. Recent studies also seem to place typhus fever in the same category. Finally, the prolonged researches of Hort and his associates (*ibidem, loco citato*) offer strong evidence for the inclusion of cerebrospinal meningitis in this paradoxical group. They have shown the meningococcus to be a nearly constant accompaniment of meningitis, but that its cultures are incapable of infecting animals. Along with this organism, however, there is an ultramicroscopical organism which passes through filters, which grows in culture media, and which is infectious to animals.

It would carry us too far to enter into the details of these and other studies, but their results seem to be definitely established. It has been suggested that in such cases as those cited, there is a symbiosis in which the filterable virus prepares the field for the bacterium. Hort offers, and cites evidence to

support the suggestion that the bacterium and the filterable virus are two phases in the life cycle of a single organism. If this suggestion proves to be correct we must modify our long accepted belief that bacteria are the simplest of all forms of living matter, multiplying asexually and by fission only.

It may be recalled that we have long known that certain tuberculous lesions may be entirely free from tubercle bacilli demonstrable microscopically, and yet may prove infective to animals. Can the minute Gram positive granules found in such material be analogous to the filterable viruses just discussed? Such a notion is not to be thrown aside lightly, for there is now sufficient evidence to make its serious consideration necessary.

These observations, to which others might be added, seem to open up a new field for bacteriological research which promises to be highly fertile and profitable. It would be well worth while for others to cultivate it.

THE SUBJECTIVE SYMPTOMS OF CHRONIC GLAUCOMA.

It is not uncommon to meet with facial neuralgia in an elderly person. Many such patients are unaware that there is anything wrong with their eyes, although they have suffered from recurrent attacks of supraorbital neuralgia, and may have noticed that they could not see well at times. Frequently they ascribe such symptoms to old age, which also serves to explain why they have to change their reading glasses so often. Yet these recurrent attacks of neuralgia and frequent changes of presbyopic glasses are the ordinary subjective symptoms of chronic glaucoma. Most of these patients consult the specialist too late to save their eyes, because neither they nor their physicians suspect the nature of the disease in its early stages. The diagnosis at this time is not easy, but it is important.

The first step toward the diagnosis is to remember that an attack of supraorbital or facial neuralgia, which has come on during a period of mental stress or bodily fatigue, causes loss of sleep and of appetite, and passes away in a few hours, may readily be the most prominent symptom of an oncoming of chronic glaucoma, or a prodromal symptom of an acute glaucoma. We are apt to think of the pain of this disease as referred by the patient to his eye, but this is not always the case. Often the pain does not seem to radiate from the eye, but from some other part of the face, like the teeth. Occasionally an observant patient tells us that objects look misty, or that he sees colored rings about lights during an attack of neuralgia, but observant patients are not common. If we see the patient while he is suffering, we may notice that one pupil is slightly larger than the other and does not react as well to light, that the eye is a little reddened about the cornea, perhaps that one anterior chamber is rather shallow, and possibly we may observe a slight diffuse cloudiness of the cornea, but after the pain has ceased we are not likely to see any changes. Invariably after the first attack of a neuralgia that ushers in chronic glaucoma has passed off, which happens in a few hours, all the ocular symptoms disappear, and no one can find any indication of trouble. The typical cupping of the optic disc does not appear until after two, three, or more such attacks, and the prognosis is not as good after as before its appearance. If the patient consults a specialist following such a first attack, the vision will be found to be normal, the tension normal, the optic disc normal, the eyeball in its entirety apparently normal, and no indication will be found from which the consultant will be justified in deciding that the eye was the seat of the cause of the neuralgic pain. It is essential that he should either see the patient during the attack of pain, or receive a graphic account of the symptoms during the attack, if he is even to hope to make a correct diagnosis. For this reason it is urgent that a patient who suffers from an attack of facial neuralgia, particularly if he is elderly, should have his eyes looked at carefully for any slight symptoms which may suggest a possible trouble there.

The second attack comes on weeks or months later, the third after a shorter interval, a fourth after one still shorter, and eye symptoms begin to persist during the intervals—lowered vision, large pupil, increased tension, excavation of the optic papilla. The diagnosis grows more and more easy, while the prognosis becomes steadily worse. Is it not well to pay close attention to a first attack of facial neuralgia in an elderly patient, to be sure that it is not caused by the eye?

RESISTING POWER IN OLD MEN.

"A man aged eighty-five years, who was in the habit of taking frequent 'nips' of any drink in which his friends would join him, was taken ill with pneumonia. Doctor Russell, of Birmingham, saw him with me in consultation on the fifth day of the attack, and we agreed that he had no chance of surviving, but the crisis came on the twelfth day; he made an uninterrupted recovery, and lived for two years afterward. The patient had had a loud systolic bruit at the apex of the heart ever since I had known him, which was about eight years."

William F. Box, a practitioner of Stratford on Avon, who communicates the foregoing case to the *British Medical Journal* for November 11th, tells also of another patient. This was a man, over ninety-

three years old, who was operated on at the age of seventy-nine years for strangulated inguinal hernia, but his condition at the time was too serious to admit of a radical cure being performed. Latterly he omitted to wear a truss, with the consequence that the hernia again became strangulated. "I was unable to reduce it after the application of an icebag, so I operated," writes Doctor Box; "I found about ten inches of small intestine in the sac, and one coil was adherent to the lower part of the sac by a band about the thickness of the little finger. The intestine was of a dusky red color, but not gangrenous; it was returned without resection. This patient also made an uninterrupted recovery. I do not know whether this constitutes a record, but I should think it did. He also has a loud systolic bruit at the apex of his heart."

The interesting point about both cases is the fact that both had a loud systolic bruit, and the writer thinks this had much to do with their recovery, as the arteries in both cases were elastic, and there were no signs of high tension.

Obituary

MARTIN I. WILBERT, Ph. M.,
of Washington, D. C.

Martin I. Wilbert, technical assistant in pharmacology in the United States Public Health Service, who died in Philadelphia on November 27th, had made for himself a unique place in the medical world. He was a pharmacist of unusual attainments, of the loftiest ideals, and of the most unremitting industry in his efforts to elevate pharmacy and medicine, and to bring them together on a higher plane of scientific accuracy. His work in the compilation of the *Digest of Comments on the United States Pharmacopœia and the National Formulary* is a monument to his industry, accuracy, and the wide range of his knowledge. He was the author of several valuable papers in the form of Bulletins, issued by the Public Health Service. He worked with the Council on Pharmacy and Chemistry of the American Medical Association, and was an influential member of the Council of the American Pharmaceutical Association.

News Items

A New Head to the Rockefeller Foundation.—Announcement is made that Mr. John D. Rockefeller, Jr., who has been president of the Rockefeller Foundation since it was chartered in 1913, has resigned, his resignation to take effect on May 15, 1917, when he will become chairman of the board of trustees. Mr. Rockefeller will be succeeded as head of the foundation by George Edgar Vincent, Ph. D., LL. D., president of the University of Minnesota and formerly dean of the faculties of arts, literature, and science of the University of Chicago. The reason given for Mr. Rockefeller's retirement is that the activities of the foundation have become so varied and important that it is necessary for some one to give his entire time to the work. It is announced further that there will be no change in the policy of the foundation.

American Hospital Association's Headquarters.—At a meeting held in New York on Saturday, November 25th, it was decided to establish in Philadelphia permanent headquarters for the association, with Dr. J. H. Walsh in charge. Doctor Walsh plans to conduct a bureau of information.

Foot and Mouth Disease in Kansas.—It is reported that an emergency quarantine has been placed on cattle shipments from neighboring States by State officials of Kansas and Missouri, because what was believed to be foot and mouth disease was observed in a carload of cattle received at Kansas City from Nebraska. Federal authorities are investigating the outbreak.

Brooklyn Medical Library Association.—The annual meeting of this association will be held on Monday, December 4th, in the Library Building, Medical Society of the County of Kings, Brooklyn, at 8:30 p. m., under the presidency of Dr. William Browning. The paper of the evening will be read by Dr. Edward E. Cornwall on Medical Notes of Early New England, 1620-1650. Dr. Robert L. Moorhead is secretary of the association.

Meetings of Medical Societies to Be Held in Philadelphia during the Coming Week.—Monday, December 4th, Wills Hospital Ophthalmic Society, Academy of Surgery, Philadelphia Clinical Association, Blockley Medical Society; Tuesday, December 5th, Laryngological Society, Medical Examiners' Association; Wednesday, December 6th, Physicians' Motor Club (directors), Philadelphia College of Physicians; Thursday, December 7th, Obstetrical Society, Southeast Branch of the County Medical Society; Friday, December 8th, Northern Medical Association.

Another Harvard Unit Goes to Europe.—A new contingent of the Harvard Surgical Unit left Boston last week for service in the British base hospitals in France. The party included six surgeons and twenty nurses who will take the place of members of the unit whose service ends on December 9th. The surgeons in the new contingent are: Dr. Francis W. Palfrey, of Boston; Dr. Paul Hector Provandie, of Melrose; Dr. Forrest Fay Pike, of Melrose; Dr. Kendall Emerson, of Worcester; Dr. Henry B. Potter, of Wakefield, R. I.; and Dr. Chauncey N. Lewis, of Boston.

New Officers of the County Medical Society.—At the annual meeting of the Medical Society of the County of New York, held at the New York Academy of Medicine, Monday evening, November 27th, Dr. J. Bentley Squiers was elected president, succeeding Dr. Frederic E. Sondern. Other officers were elected as follows: First vice-president, Dr. Charles H. Peck; second vice-president, Dr. Ludwig Kast; secretary, Dr. Daniel S. Dougherty; assistant secretary, Dr. J. Milton Mabbott; treasurer, Dr. Frederic E. Sondern; censors, Dr. William S. Gottheil, Dr. Ward B. Hoag, and Dr. Alexander Lyle.

Personal.—Dr. John McMullen, who is the surgeon in charge of the trachoma investigations of the United States Public Health Service, addressed the National Committee for the Prevention of Blindness, at the New York Academy of Medicine, on Friday afternoon, November 24th. His subject was Trachoma in Eastern Kentucky and the Work of the United States Public Health Service in Its Treatment and Control. The address was illustrated by lantern slides.

Dr. Charles A. Powers, of Denver, is home after six months' service as surgeon at the American Ambulance Hospital, in Paris. He will return to France and resume his work in the hospital on April 1st.

Dr. Daniel Crosby has been appointed consulting laryngologist to the Huntington Hospital, Boston.

Dr. Channing Chamberlain Simmons, of Boston, has been appointed assistant surgeon to the Huntington Hospital.

Dr. Chevalier Jackson, of Pittsburgh, Pa., has been elected by the trustees of Jefferson Medical College and Hospital, Philadelphia, to succeed the late Dr. D. Braden Kyle as laryngologist to the institution.

The Work of Sydenham Hospital.—The annual report of this institution shows that 2,057 patients were treated at the hospital during the year and 32,971 at the dispensary. The per capita cost of patients was about $2.40. During the year 14,186 free treatments were given. The report shows that the hospital is practically free of debt. The deficit of $6,680.64 is the lowest ever recorded, and it is expected it will be wiped out entirely by gifts made by Mrs. Isaac Guggenheim and Mrs. Frances Cohen and by a theatrical benefit which will be given by the Shuberts in the near future.

The Children's Home Bureau.—This bureau was organized on Thursday, November 23d, at a meeting held in the office of Dr. John A. Kingsbury, commissioner of charities. It will be conducted in connection with the department of charities, but will be maintained by private subscriptions. The object of the bureau is to find private homes for dependent children, and it is believed that one thousand children a year can be placed in carefully selected private homes. Up to the present time $150,000 has been subscribed, which it is believed will be sufficient to maintain the bureau for about three years. Doctor Kingsbury is president.

American Electrotherapeutic Association.—At the annual meeting of this association, held recently in New York, the following officers were elected: President, Dr. J. Willard Travell, of New York; vice-presidents, Dr. William Martin, of Atlantic City, N. J., Dr. Frank B. Gardner, of Boston, Dr. Frank E. Peckham, of Providence, R. I., Dr. William L. Clark, of Philadelphia, and Dr. A. B. Hirsh, of Philadelphia; treasurer, Dr. Emil Heuel, of New York; secretary, Dr. Byron S. Price, of New York; registrar, Dr. Frederick M. Law; board of trustees: One year, Dr. William Benham Snow and Dr. Frederick de Kraft, of New York; two years, Dr. Frederick Harris Morse, of Boston, Mass., and Dr. John W. Torbett, of Marlin, Texas; three years, Dr. Jefferson D. Gibson, of Denver, and Dr. Edward C. Titus, of New York.

Aftercare of Poliomyelitis Patients.—The New York Committee on the Aftercare of Infantile Paralysis Cases, which grew out of a series of conferences called by the commissioner of health to consider the work of caring for the children convalescing from poliomyelitis, has undertaken three main lines of work: First, to coordinate the work of the dispensaries and the nursing agencies; second, to organize dispensary transportation for children who required it, and third, to raise funds to aid in the treatment, home care, and training of these children. The committee consists of a general committee, representing the department of health, the department of public charities, the hospitals, dispensaries, nursing associations, and other welfare agencies; a committee on transportation, comprising more than a hundred names; a medical council of twenty-one orthopedists, neurologists, and pediatrists; and a finance committee of two hundred men and women. An account of what has been accomplished thus far by the committee appears in the December 2d issue of the *Weekly Bulletin* of the Department of Health.

An Unusual Breeding Place for Mosquitoes.—Acting Assistant Surgeon W. J. Stewart, United States Public Health Service, on duty at La Guayra, Venezuela, reported recently that there had been a much larger number of mosquitoes than usual in the offices of the American consulate and that a careful search of the usual breeding places, including rain gutters, failed to reveal where they were breeding. There was in use in the office a water cooler of the type in which water from a large inverted bottle passes through a porcelain compartment surrounded by an ice chamber. One day in drawing off from the ice chamber some of the water resulting from the melting ice, mosquito larvæ were found in the water and on complete drainage of the ice chamber a considerable number of larvæ were found. The water and larvæ were inadvertently thrown away before the type of mosquitoes which had been breeding in this ice cold water was determined. The cleaning of the ice chamber and careful daily attention to it were followed by the total disappearance of mosquitoes from the offices.

American Health Resorts.—The European war, it is said, has had a considerable influence in increasing the patronage of American health resorts. Many Americans who usually go to foreign spas, have visited home institutions instead. Furthermore, numerous residents of other neutral countries have come to the United States in search of health, who would in other conditions have gone to Carlsbad, Homburg, or the hundred other health headquarters of Europe. This is particularly true of wealthy residents of Central and South America. In the last year the Battle Creek Sanitarium, for example, has had about two hundred patients from abroad. In the last three months, the institution has had letters of inquiry from prospective visitors residing in the following lands: Cuba, Caiman Islands, Mexico, San Salvador, British Guiana, Venezuela, Colombia, the Argentine, Uruguay, Peru, Honduras, Italy, Switzerland, Russia, England, Germany, India, Japan, the Belgian Congo, and Australia.

Gifts and Bequests to Hospitals.—The Hartford, Conn., Hospital will receive $2,500 by the will of Alice E. Lothrop.

The will of Catherine E. Brown, who died in Brooklyn on October 21st, contains, among others, bequests of $500 each to St. Joseph's Hospital, St. Francis's Hospital, and St. Rose's Home for Incurable Cancer.

By the will of Mrs. Annie A. Peckham, who died in New York on October 30th, the following institutions will receive $10,000 each: St. Mary's Free Hospital for Children, the New York Association for Improving the Condition of the Poor, the Sea Breeze Experimental Hospital at Coney Island, the Morristown Memorial Hospital, and All Souls Hospital, of Morristown, N. J.

By the will of Marcus M. Darr, late of Buffalo, N. Y., the Hahnemann Medical College and Hospital of Philadelphia will receive $40,000.

By the will of the late Louis S. Fiske, of Bryn Mawr, Pa., the Children's Hospital of Philadelphia will receive $25,000.

Private Pavilion of the Montefiore Home and Hospital for Chronic Diseases.—Five years ago a movement was started by Dr. Sigfried Wachsmann, medical director of the Montefiore Home and Hospital, to make provision for persons who were not charity patients and yet no more eligible for the private pavilions of the general hospitals than the inmates of the Montefiore Home were for the general wards of other hospitals. The directors of the institution recognized the necessity and four of them, Mr. Jacob H. Schiff, Mr. Samuel Sachs, Mr. Sol. B. Guggenheim, and the late Mr. Ferdinand Sulzberger, donated a sum amounting to a quarter of a million dollars to build the pavilion as it stands today. The ground was broken on May 7, 1914, and the first patient moved in November 20, 1916. Fifty patients can be accommodated.

The construction of the building with its special equipment was based on many years' experience with the needs of the main institution, and the plans were drawn by the same architects who designed the main building, Messrs. A. W. Bonner and Buchman and Fox. The object of the private pavilion is to combine the advantages of a special hospital with the comforts of a hotel or club. Many physicians know families where the presence of a chronic invalid is upsetting the entire home life, and in spite of the best intentions of the other members of the family and ample means, no satisfactory adjustment can be made either for the patient or his relatives. The attending physician is severely handicapped because few of the treatments which have proved effective in chronic cases can be readily administered in private homes or hotels, and it is difficult and sometimes impossible for the patient to make daily visits of short duration to the hospitals equipped with the means of administering such special treatment.

The physical treatment consists of hydrotherapy, electrotherapy, mechanotherapy, thermotherapy, and manual massage, in addition to such medical or surgical treatment as the case may require. In addition, the patient will have the advantage of social intercourse when able to be about. Any reputable physician can receive the privileges of the private pavilion by applying to the board of trustees.

Modern Treatment and Preventive Medicine

A Compendium of Therapeutics and Prophylaxis, Original and Adapted

THE THERAPEUTICS OF A PHARMACOLOGIST.

By A. D. Bush, M. D.,
Professor of Pharmacology and Therapeutics, University of Southern California.

Forty-sixth Communication.

HABITUAL CONSTIPATION.

In considering the treatment of constipation it is desirable to ascertain not only the predisposing causes, but also the particular portion of the alimentary tract which is not functioning properly. The predisposing factors, like sedentary habits, neglect of regularity at stools, too concentrated diet, insufficient intake of water, must all be regulated by receiving suitable attention, as must also those other factors having to do with some peculiarity or derangement of intestinal activity. An abnormal length of small intestine with high absorptive power, a lessening amount of the mucous secretions therein, slackened peristalsis—any or all of these may result in undue inspissation of the intestinal contents, thereby making defecation difficult. In such cases the trouble may usually be overcome by increasing the proportion of coarse vegetables in the diet, and also the amount of water ingested. The indigestible vegetable detritus stimulates both secretion and peristalsis, and delays absorption; so the material passing into the large intestine, being more fluid, is more readily moved along toward the outlet. If a drug seems temporarily desirable (and its use must be temporary), then those drugs should be selected which have localized action. By stimulating peristalsis, and probably by provoking exosmosis, the salines greatly increase the fluidity of the material passing through the ileocecal valve. Rhubarb and podophyllin act on the small bowel by stimulating secretory activity, and probably by some irritation cause increased peristalsis, but as podophyllin does not produce much effect if the bile is markedly deficient, some of the bile salts should be given with the mandrake if so called "torpid liver" accompanies the constipation.

When the loss of function is situated in the large bowel an increase of coarse vegetables in the diet is likewise usually beneficial; but, if a drug seems indicated, then aloes should be used as a cathartic having selective action on the large intestine. Not infrequently this drug gives excellent emergency results in a certain class of people suffering from alimentary plethora, in which group the large bowel has gradually become a distended depot for the storage of accumulated waste material. With this group aloes often proves a peculiarly effective purgative—in fact, a clever but not overethical practitioner near Boston has acquired extended reputation among the laity for successful treatment of many disorders largely because of a shrewd recognition of the value of the A. B. and S. pill in relieving distraught patients of overloaded colons, and the many harassing ills incident thereto. Aloes both stimulates secretory activity and peristalsis, the belladonna tends to make the peristalsis hypalgesic, while the strychnine heightens reflexes, thereby tending toward a restoration of the normal function.

Perhaps the great majority of cases of habitual constipation are due to depressed tonicity of the rectum, especially among women. How frequently the gynecologist is hampered in his diagnostic investigations, or debarred entirely, by the presence in the patient's rectum of scybalous masses, concerning which his patient is totally unaware. This experience of the gynecologist is indicative of a condition very prevalent among women, due in most instances to habitual postponement of Nature's call until finally the rectum becomes so depressed in sensitivity as to degenerate from a serviceable channel into a reservoir for the storage of rapidly solidifying material. In such a case, beside strict attention to hygienic and dietetic measures, assistance may be gained from cascara which stimulates secretory activity in the rectal region. To the cascara may well be added strychnine for its tonic effect. No other combination acts so favorably with such a minimum of aftereffects.

Mercurial Stomatitis.—Douglass W. Montgomery (*Medical Record*, Nov. 18, 1916) states that mercury seldom causes trouble in the mouth in infancy, but in the adult the susceptibility is marked. In giving mercurial treatment the patient is advised to brush the teeth three times daily after each meal with a tooth powder or paste containing potassium chlorate. In the actual presence of mercurial stomatitis hydrogen peroxide is almost a specific, used in dilute solution. Severe cases of inflammation of the gum margin may require undiluted peroxide, or equal parts of peroxide and twenty per cent. silver nitrate. Liquor alumini acetatis one dram in a glass of water is an excellent mouth wash or gargle. A solution of one heaping tablespoonful of boric acid in a quart of infusion of slippery elm bark as recommended by Brocq makes a smooth and acceptable mouth wash. For erosions ten per cent. chromic acid solution is best, and gives better results if used every two or three days rather than daily. If the gums are soft and swollen, they may be brushed with silver nitrate solution ten to twenty per cent. followed immediately by ten per cent. chromic acid. The elimination of the mercury is of great importance, and if inunctions have been used they must be stopped, and a hot bath with plenty of soap given to free the skin of the mercurial ointment. Baths of water containing Vlemincki solution should be given. This solution is made by boiling five ounces of sublimed sulphur with twenty drams of quicklime in fifty ounces of water until thirty ounces remain. A dose of castor oil should be given to cleanse the intestinal tract, and a diuretic mixture given together with plenty of warm drinks, and a hot bath followed by two hours' relaxation. Atropine is administered by some to relieve the salivation which is really tormenting.

Chloroform in Status epilepticus.—Leigh F. Robinson (*Journal A. M. A.*, November 18, 1916) reports a large series of patients presenting this severe epileptic manifestation submitted to treatment by three different methods to determine the value of each. For three months all patients were treated almost exclusively with high colonic irrigations and saline purges; during the second three months all were treated in the same manner with the addition of chloroform anesthesia when the other treatment failed; and the last three months were devoted to the restricted use of chloroform anesthesia alone. All patients, irrespective of the treatment otherwise followed, received fluidextract of cascara nightly, and a dose of castor oil or saline about once every ten days. The results showed that the treatment in no case decreased the frequency of the attacks, but that these occurred at fairly uniform intervals in spite of treatment. The time required for recovery from a condition of status and its effects depended upon the promptness with which an attack was checked. The study indicated that chloroform should be used early in every case of status epilepticus and that, although high enemas and laxatives did not produce material benefit, it would be advisable to employ suitable means to overcome a tendency toward constipation.

A New Method of Blood Transfusion.—G. Blechmann (*Bulletin de l'Académie de médecine,* October 10, 1916) finds artery to vein transfusion, whether by direct anastomosis or through a cannula, ill suited as an emergency measure, and disadvantageous in that a radial artery of the donor is sacrificed. The Kimpton and other reservoir methods, on the other hand, require fragile and specially prepared apparatus, inconvenient in military surgery. In the author's method vein to vein transfusion is effected by application of the siphon principle; the blood may be diluted with saline solution through a lateral inlet tube, and the apparatus consists chiefly of rubber tubing, which is well known to retard coagulation. The trocar needles of the donor and recipient are connected with pieces of tubing respectively ten and fifty cm. long, these in turn being united by a glass T tube, the side outlet of which is connected with a tank containing sterile saline solution. By suitable manipulation of clips on the three tubes, the flow in the apparatus can be started, the blood diluted, and saline solution introduced at will in the donor after the transfusion. The difference of levels is fifty-five cm., and with a trocar needle having an internal diameter of 1.3 mm., seventy c. c. of blood pass through a minute. In beginning the transfusion the recipient's needle is first introduced, saline solution run in to insure its proper situation in the vein, and the donor's needle then inserted. The latter being at a higher level, blood at once descends to the recipient when the clip on the tubing is loosened. The venous blood transfused has the advantage of being less coagulable than arterial blood. Coagulability is also reduced by running into the blood 0.5 per cent. saline or 4.7 per cent. glucose solution from the tank above. The apparatus is also useful for venesection, alone or followed by saline infusion, as in intoxication by asphyxiating gases, carbon monoxide, etc.

The Oral Administration of Antitoxins.—McClintock and King (*Journal of Infectious Diseases,* October, 1916) report a series of experiments with antitoxins for prevention of diphtheria, tetanus, and possibly sepsis, with some observations on the influence of certain drugs in preventing digestion and promoting absorption from the alimentary canal, and give some very interesting conclusions. In general terms they find that the antitoxins for diphtheria and tetanus may be given by mouth and absorbed in sufficient quantity to show markedly antitoxic properties in the blood of the treated animal. These results have been obtained by using certain drugs with the serum; on the one hand, drugs that inhibit digestion; on the other, those that promote absorption. If such drugs as tricresol, salol, chloroform, and opium have been added there seems to be a regular rate of absorption. They show, also, that the toxins of diphtheria and tetanus are absorbed from the alimentary canal, provided that digestion is inhibited. This suggests a method for slow, gradual immunization of animals or men that is at the same time much easier and safer than the hypodermic administration of toxins.

Definite Treatment of Pneumonia.—Solomon Solis Cohen (*Dominion Medical Monthly,* October, 1916) outlines the treatment of pneumonia as follows: A—General: 1. An abundance of fresh air, preferably in the open, carefully preserving the warmth of the body. If necessary, external heat should be used. 2. Good nursing, rest, proper diet, and the free use of water. Copious diuresis should be especially sought. 3. The thorax should be kept warm by poultices during the day and a lamb's wool jacket at night. It may be preceded by a mustard or flour poultice. 4. Chlorides should be administered by a saline infusion, by alkaline saline beverages, or by the administration of a mixture of the chlorides in capsule. 5. Cleansing and disinfection of the upper air passages by local applications to the throat or by inhalations. B—Special: 1. Quinine should be given promptly in doses of from fifteen to twenty-five grains repeated every three hours. The dose should be gradually lessened and the interval increased. When the temperature falls below 102.5° F. the quinine should be omitted, to be resumed when the temperature reaches 105° F. Quinine is best given in the form of quinine and urea hydrochloride, twenty-five to fifty per cent. solution, injected intramuscularly. Ethylhydrocuprein, because of the narrow interval between the therapeutic and toxic dose, should not be generally used. 2. Cocaine, caffeine sodium salicylate, adrenaline, and posterior pituitary principle are used when necessary to maintain the systolic blood pressure at or above the level of the pulse frequency. 3. Cardiants—when the difference between the diastolic blood pressure and the rate of respiration becomes less than ten it is considered a danger signal and camphor or digitalis should be administered. 4. Auxiliary and symptomatic measures: wet and dry cupping, venesection, and the use of drugs, such as strychnine, atropine, opium, and musk, when a special indication exists. 5. Tincture of ferric chloride is given when the quinine is withdrawn and is continued during convalescence. 6. In prolonged cases an autogenous vaccine may be used.

Treatment of Eclampsia.—S. S. Coe (*Charlotte Medical Journal,* November, 1916) emphasizes two points in the treatment: The unquestionable value of prophylaxis and elimination, and the importance of early, unremitting, and systematic medical supervision of every pregnancy. Urinary examinations should be made every month up to the seventh month and every two weeks thereafter. All vomiting should be regarded with suspicion, especially if it occurs in the later weeks. Of the methods of elimination, repeated colonic irrigations with salt solution are of very great value. In certain cases intravenous infusions or hypodermoclyses may take the place of colonic irrigations. In the active treatment of eclampsia a combination of elimination, controlling the convulsions, and effecting delivery under complete anesthesia by some method which injures the patient only slightly, should be carried out. Chloroform, or veratrum viride, ten to twenty minims of the fluid extract hypodermically, followed by five to ten minims every half hour until the pulse is reduced to sixty, is a trustworthy procedure. Pilocarpine should never be used. Early and active catharsis should be obtained by croton oil or compound jalap powder. Oxygen is an invaluable stimulant. The best method of emptying the uterus is by bimanual dilatation.

Anthelmintics. — C. Bachem (*Medizinische Klinik,* October 1, 1916) states that for the removal of tapeworms and other intestinal parasites the desiderata include an effective anthelmintic which shall be prompt in action and relatively nonabsorbable from the intestine; that the parasites shall be swept out of the intestine promptly by means of a purge, given along with, or very shortly after the anthelmintic; that the anthelmintic shall be given after a night's fast; and, lastly, that the preparatory treatment shall not weaken the patient. For tapeworms the most effective agents are aspidium, granatum, cusso, and kamala. Of aspidium the single total dose of ten grams of the oleoresin should not be exceeded, and the treatment should never be repeated on the following day. Contrary to general opinion the best purgative to use following the dose is castor oil. The aspidium may be given very satisfactorily, either in one gram gelatin capsules, the total dose to be taken within half an hour, or it may be given in the form of the following palatable prescription:

℞ Oleoresinæ aspidii, ...8.0;
Confectionis sennæ, ...30.0;
Glycerini, ...5.0;
Syrupi, ...25.0.
M. et Sig. To be taken in two portions within one hour.

Granatum can be given in the form of a draught of the following composition:

℞ Granati, ...30.0-50.0;
Aquæ destillatæ, ...300.0;
Macera per hor. xii; cole cum aqua, ...200.0;
Nunc adde syrupi zingiberis, ...30.0.
Sig. Take on empty stomach in two portions; follow in half hour with tablespoonful of castor oil.

Cusso can be given in doses of twenty grams or more in a suspension, in the form of an electuary, or as tablets. Kamala is the mildest and least likely to be harmful of the anthelmintics of this class, and can be given in cachets or as an electuary in doses of eight to ten grams to adults, or two to six grams to children. To remove the ascaris, santonin and chenopodium are the most effective. Santonin should never be given in a single dose greater than 0.1 gram and never in an amount greater than 0.3 gram a day. It should be preceded by a laxative. It may be given in tablets, as a powder, in troches, or in solution in castor oil. Eight to fifteen drops is the proper dose of oil of chenopodium, given on sugar, in capsules, or in an emulsion. For the oxyuris, naphthalene in doses of 0.1 to 0.5 gram may be given internally, and various forms of enemas may be used to destroy the worms in the rectum. Among these may be mentioned salt solution, vinegar, soap and garlic, salicylic acid (one in 1,000), or chinosol (one to 8,000). The medicated enema should be preceded by a cleansing one. The napthalene may be given in the form of the following powder:

℞ Naphthaleni, ...3.0;
Sacchari, ...6.0;
Olei citri bergamiæ, ...0.06.
M. et divide in chartulas No. X. S. One, three times a day, between meals.

Treatment of Malignant Disease About the Mouth.—George E. Pfahler (*Journal A. M. A.,* November 18, 1916) states that prophylactic measures are of the greatest importance in the case of lesions about the mouth. They should include the treatment or removal of jagged teeth; the treatment of pyorrheal ulcers; the prohibition of smoking in smokers' stomatitis, and in leucoplakia, in which also the patient should be treated for syphilis and the areas destroyed by electrothermical coagulation if fissures persist in them. Ulcers, fissures, crusts, and warts on the lower lip or at the angles of the mouth should be destroyed at once by electrothermical coagulation, and the glands of drainage should be given deep x ray treatment. When a malignant growth has developed in this locality it should be treated as soon as possible, and among the several methods of treatment the author prefers the combined practice of destruction of all of the affected tissues by electrothermical coagulation, to be followed by prolonged, thorough treatment with full doses of penetrating x rays applied both to the site of the lesion and to the glands of drainage. The advantages of the coagulation method are: Devitalization of the neoplasm without actual destruction of healthy tissues; it obviates the danger of implantation and dissemination of malignant cells as there are no raw surfaces produced, and no blood or lymphatic vessels are opened; there is no hemorrhage, except possibly some secondary bleeding in tongue cases; and, finally, there is no danger of infection locally. The method also gives the best cosmetic results, as there is a minimum of damage to healthy tissues. The only place for the use of radium, in the author's opinion, is in the treatment of lesions within the mouth, such as those of the tongue, cheek, and inner aspect of the lip. For regions in which the x ray can be used radium has no advantages over the former, and its dose cannot be so accurately controlled. In some cases surgical removal of the neoplastic tissues may be tried, but the proper use of the electrothermical coagulation method of treatment meets every requirement of surgery and is preferable.

Radium in Cancer and Other Skin Lesions.—Frank E. Simpson (*Journal A. M. A.*, November 18, 1916) asserts that although radium and the x rays have much in common, the former has advantages over the latter, chiefly in being both selective in action, and of high destructive power. Radium seems specially indicated, because specially efficient, in the treatment of cancer of the skin, certain forms of vascular nævi, keloid, certain cases of lupus vulgaris or erythematosus, in sycosis, lichenification, localized pruritus, and particularly in pruritus ani. In over 200 cases of cancer of the skin treated with radium by the author recovery has been almost invariable. In cancer of the mucous surfaces the results have been less gratifying, and at times very disappointing.

Radium in Malignant and Nonmalignant Conditions.—Gaston Torrance, W. C. Gerwin, and Walter A. Weed (*Charlotte Medical Journal*, November, 1916) report the treatment of sixteen cases of epitheliomata with gratifying results. If of the cutaneous surface—flat and superficial, and not accompanied by ulceration—they give twenty to 100 mg. hours, using a flat half strength applicator with no screening except one thickness of pure rubber dam. If the cosmetic effect is to be considered, screening up to one mm. of silver may be used, with a corresponding increase in the length of exposure. Epitheliomata of the mucous surfaces are much more resistant. In carcinomata of the breast radium has been used immediately after operation to prevent recurrence. The treatment of carcinomata of the uterus has been very satisfactory, and good results have also been obtained in carcinoma of the rectum and bladder, Paget's disease of the breast, sarcoma of the breast, sarcoma of the parotid, sarcoma of the intestine, goitre, Hodgkin's disease, and fibroids of the uterus.

Treatment of Rickets.—Eric Pritchard (*British Journal of Children's Diseases*, October, 1916) gives his opinion that rickets is due to an excess of food and not a deficiency. He reports a child two years old, who had been breast fed for four to five months, had solid food at nine to ten months, and who was taking a fairly liberal diet at the time of admission. Curvature of the back was noticed from the sixth month on. The legs have always appeared abnormal. On admission the child was anemic and flabby and lay absolutely motionless with legs fully extended. The bones showed changes of rickets. The child was pot bellied. The x ray showed the bones of the spine to be poorly mineralized. After being in the hospital for three months there was a marked improvement and a considerable loss of weight. The theory upon which the child was treated was that the rhachitic symptoms were caused by a relative excess of food calling into play certain protective mechanisms producing an acidosis. This led to an anemia which the organism had attempted to counteract by compensatory overactivity of the hemogenetic centres in the long bones. The acid toxemia led to the paresis of the muscles and the general debility. The treatment consisted in creating a demand for food by massage, resistance exercises, cold douches, and open air treatment. Alkalies were given in large doses and iron and phosphorated codliver oil were also administered.

Rest of Lung by Posture.—Gerald B. Webb, Alexius M. Forster, and F. M. Houck (*Journal A. M. A.*, November 11, 1916) state that there is a tendency for the consumptive patient to lie on the side of the normal or less affected lung, thus giving the greater work to the poorer lung. Most normal persons tend to sleep on their right side and it is interesting to note that the majority of advanced tuberculous lesions are in the left lung. The value of rest of the lung has been demonstrated by artificial pneumothorax. The expansion of the lower lung is materially decreased by lying on the side. These observations led the authors to try the influence of postural rest in pulmonary tuberculosis, aided by placing a small firm pillow under the dependent side. The results were promising, showing in some cases cessation of fever, diminished expectoration, and a decreased tendency to relapses. Patients have been able to carry out this plan of postural rest for twenty hours a day for months at a time. It is probable that there is an increased congestion in the dependent lung, and patients have been observed who had hemorrhages after lying on the side of greater involvement. This fact should be taken into consideration in the application of this form of treatment.

Results from Pituitary Extract in Obstetrics.—Lyle G. McNeile (*American Journal of Obstetrics*, September, 1916) points out that many cases are being recorded in which the following complications have followed the use of this drug: Post partum uterine atony, fetal asphyxia, maternal collapse, eclamptic convulsions, tetanus of the uterus, premature placental separation, and rupture of the uterus. In his own experience uterine tetanus has followed as little as five minims of the extract in two instances. A greater tendency to such tetanus in primiparæ than in multiparæ was noticed, and in many instances restoration of normal contractions did not follow, a low forceps operation becoming necessary. Fetal asphyxia was likewise noted in many primiparæ, though it was never fatal. Post partum atony, with alarming hemorrhage in several cases, was noted particularly in instances of prolonged labor, and of multiparæ in which several pregnancies had occurred in rapid succession. Such considerations led McNeile to the assertion that this drug has absolutely no place in normal obstetrics. He formulates, moreover, the following conditions that should govern its use: 1. Complete dilatation and effacement; 2, ruptured membranes; 3, longitudinal presentation; 4, in cephalic presentations there should be no deflection of the head, and the drug should be used only in vertex and breech presentations; 5, there should be no disproportion between presenting part and pelvis, previous accurate knowledge of the internal pelvic measurements, pelvic contour, and outlet measurements being essential; and, 6, the presenting part should be completely engaged, i. e., the greatest diameters of the presenting part must have passed below the pelvic inlet. In a case of rupture of the uterus following pituitary extract, which the writer reports, the head was well engaged, dilatation complete, the membranes ruptured, and the uterine contractile strength decreased, but the existence of an obliquely contracted pelvis had not been recognized.

Bismuth Subnitrate in the Treatment of Acute Urethritis.—H. W. Howard (*Urologic and Cutaneous Review*, November, 1916) compares the urethra to a sinus, and the bismuth is applied to it in the same way. The urethra is put at rest by restricting the fluids so that the patient urinates only three times daily, before retiring, on arising in the morning, and at the visit to the doctor. The injection is made as follows: A dram of bismuth is added to an ounce of sterile water. After being well shaken a syringeful is drawn off. The contents of the syringe are injected into the urethra, which is held upright and maintained in this position for about two minutes. At the end of this time the supernatant water escapes and the bismuth is settled in the deeper parts. This is done morning and evening by the patient, and is supplemented by the use of a five per cent. collargol solution which is injected by the physician about noon.

Treatment of Meningitis.—Walter Broadbent (*Brit. Med. Jour.*, October 28, 1916) states that pneumococcal meningitis is still thought to be almost invariably fatal, but he reports several cases from his own experience in which recovery took place following the use of Pane's serum. The first was that of a child between three and four years of age who recovered under treatment with 0.2 gram of hexamethylenamine every four hours and Pane's pneumococcus serum by mouth, on an empty stomach. The serum was given in doses of five mils daily for the first three days, then on alternate days, and finally twice weekly. After the third day slow, but steady improvement began, and recovery was complete within three months. Two other similar recoveries in children were secured from the oral administration of this serum, always on a fasting stomach. One case in an adult also recovered under 1.3 gram of hexamethylenamine every four hours and ten mils of Pane's serum subcutaneously every other day for four doses and every third day for three more doses.

Radioactivity of Antirrheumatic Remedies.—E. Zueblin (*Lancet-Clinic*, November 4, 1916) describes an investigation of such drugs as the salicylates and sodium bicarbonate with the fontactoscope, an instrument which, used in the manner described by him, permits the finding of radioactive energy when present in quantities too small to be ascertained by the most delicate balance, or microscope, or even to be identified with the spectroscope. Either fluids or solid substances can be tested directly for their ionization or radiation. From Zueblin's previous investigations it was apparent that magnesium sulphate and other salts are capable of emitting electrical radiant energy similar to, though much weaker than that of radium, thorium, etc. From the present research it is concluded that salicylic acid and sodium salicylate likewise emit chemical rays, the alpha radiation prevailing over the beta, especially in the case of the salt. In the case of sodium bicarbonate the alpha radiations exceeded the beta variety at the start of the experiment, but later the beta radiations became the more abundant. The radiations from the salicylates may play a role in their therapeutic action. Exposed to the air, however, or simply preserved in a bottle, these substances lose their radiating strength. Attention is called to the fact that the alpha rays of radium have power to check the development of certain microorganisms. Zueblin finds it possible to convert weak radioactive substances artificially into strong emanators. This was accomplished, for example, by exposing magnesium sulphate to a 100,000 volt high frequency current for ten minutes. It is also possible to make a selection in the rays imparted to the substance, alpha or chiefly beta and gamma being charged at will. According to tests, such substances will remain radioactive for over a year—possibly several years.

Local Reactions to the Pasteur Treatment.—J. C. Geiger (*Journal A. M. A.*, November 18, 1916) states that these reactions are well recognized, but their frequency and times of occurrence have not been carefully studied. In a series of 641 cases these reactions were present in essentially 100 per cent., occurring between the sixth and ninth days and again between the fourteenth and eighteenth days. In only one case did they occur daily. In one case, only, were the reactions absent. In a case with paralysis complicating the treatment all of the reactions were greatly increased at the time of the onset of the nervous symptoms. The reactions were regarded as manifestations of a hypersensitiveness of the patient to the injection of nerve tissue. They had no relation to immunity.

Hypnotic Suggestion in Military Cases.—J. Bennett Tombleson (*Lancet*, October 21, 1916) states that as the result of an experience of eighty cases of various forms of nervous and mental disturbance due to war conditions he has found hypnotic suggestion a most valuable therapeutic measure, especially if employed within a reasonable time of the development of the affection. The greatest degree of success was secured in shock psychasthenia and neurasthenia, and very good results in hyperthyroidism. Practically all patients of the first two types of disorder were cured and returned to duty or to work, and the cures were permanent. In most instances it was necessary to induce the state of somnambulism for the best results.

Preparation of Stable Colloidal Antimony.—Upendra Nath Brahmachari (*Lancet*, October 21, 1916) reports the remarkable therapeutic properties of antimony in several protozoal diseases. The increasing appreciation of the value of metals in colloidal form has led to attempts to prepare a stable colloidal antimony, but so far with poor success. The author states that it may be prepared in stable form by the following method: A current is passed in sparks from an induction coil, and an eight volt accumulator between two aluminum foil electrodes immersed in chloroform containing coarse particles of metallic antimony. The antimony passes into a powdery state and some goes into solution. When the chloroform is distilled off a tardy residue of colloidal antimony is left. This can be dried in a desiccator, in air, or even over a Bunsen burner without materially affecting it, and may be employed in the preparation of solutions of the drug in colloidal form.

Miscellany from Home and Foreign Journals

Epidemics of Pemphigus neonatorum.—Frederick Howard Falls (*Journal A. M. A.,* Nov. 18, 1916) states that this condition, occurring chiefly in newborn babies and in epidemic form has been found to be due to a peculiar strain of staphylococci, indistinguishable from the ordinary forms except by its pathogenic characteristics. This strain has proved pathogenic for the lower animals, but in them did not produce the typical pemphigoid lesions. When inoculated into the author's arm it produced the typical lesions from which the organism was recovered in pure culture. The disease was found to be highly contagious, transmissible through a third person, and one which demanded the closest individual precautions and complete isolation for its control. It yielded readily to treatment by applications of two per cent. ammoniated mercury ointment after rupture of the vesicles.

Diagnosis of Malignant Tumors of the Liver.—Andrea Ferrannini (*Riforma medica,* Oct. 30, 1916) avers that in cases of doubtful diagnosis between hydatid cyst and malignant tumor of the liver the following factors favor malignancy, namely, age over fifty years or even slightly below, marked hepatic enlargement, multiplicity, and induration of the liver, tumors, absence of eosinophilia and of leucocytosis in general, continuous presence of grave disturbance of hepatic function especially deficiency of urea, nitrogen, and a high grade of urobilinuria, and the coexistence of a gastric syndrome similar to that of gastric carcinoma in the absence of this latter disease. Furthermore malignant tumors of the liver should be considered as more probably sarcomatous than carcinomatous when the liver enlargement is very marked, and if at the same time there are not extraabdominal metastases, ascites, or especially jaundice.

Absence of Rise of Temperature after Tuberculin.—Duncan Forbes and C. W. Hutt (*Lancet,* October 28, 1916) report two cases to show that persons with pulmonary or other forms of tuberculosis, either early or late, may fail to react to a diagnostic injection of tuberculin with a rise of temperature above normal. The first case was that of a man who was tested with subcutaneous doses of tuberculin up to 0.01 mgm. while in the early stage of pulmonary tuberculosis and failed to show any rise of temperature. This same patient again failed to react with fever when tested over a year later, although then his pulmonary condition was active and his sputum contained tubercle bacilli, demonstrated microscopically and by guineapig inoculation. The second case was that of a child two years old suffering from tuberculous abscesses. This patient failed to show fever after a dose of 0.001 mgm. of tuberculin. Similar observations have been made upon animals known to be actively tuberculous. Although such cases as these are rare they indicate that the absence of a febrile response to tuberculin is not absolutely certain evidence that the subject is not tuberculous.

Meralgia paræsthetica.—W. J. Rutherfurd (*Brit. Med. Jour.,* October 28, 1916) states that this affection—a neuritis of the external cutaneous nerve of the thigh—is of less infrequent occurrence than generally supposed, and that he has seen a dozen cases in the last ten years, five in soldiers in the past nine months. It may be bilateral, but is more commonly unilateral and its characteristic feature is the restoration of the neuritis to a single sensory nerve. Sensation over the area of distribution of this nerve is lost so far as the finer grades are concerned, for touch, heat and cold, perception of points, and for slight pain. The motor fibres are unaffected. The skin over the affected region is usually slightly thickened, and may show signs of baldness from atrophy of the hair follicles. There is local loss of the phenomenon of goose flesh. Perverted sensations are present in the analgesic area, such as shooting pains, scalding, tearing, or twisting of the flesh. Such sensations are usually transitory, but are prone to recur frequently, especially during use of the extremity, and may cause great disability. The cause of the condition is unknown, but there is some reason to believe that there may be a pinching of the nerve fibres in their passage through the fascia. Treatment is unavailing except operative incision of the fascia at the point of emergence of the nerve.

Meningeal Symptoms in Relapsing Fever.—Petzetakis (*Bulletin de l'Académie de médecine,* October 10, 1916) writes concerning a number of cases of relapsing fever recently observed in a military hospital in Athens, Greece, and in private practice in that city. A single blood examination at times proved misleading in the diagnosis. Several examinations should be made, for the blood from the finger may show no spirilla for one to three days, though later many may be found. Numerous cases were at first mistaken for typhoid fever or meningitis. Meningeal symptoms may appear on the first day, and usually with the first rise of temperature. Four out of fifteen cases showed a complete meningeal syndrome, including neck rigidity, marked Kernig's sign, and intense headache; in three other cases neck rigidity alone was noted. The headache is ascribed to a marked increase in cerebrospinal pressure, lumbar puncture alone relieving it, and yielding a strong jet of cerebrospinal fluid, fifty to eighty c. c. of which spurted out in a few seconds. This fluid was clear, free of spirilla, of other organisms, and of cells, and with normal albumin content. In one case, however, an aseptic puriform fluid was obtained. In the treatment, 0.6 gram of neosalvarsan intravenously induced a crisis, with arrest of the initial paroxysm, and prevention of the second. The drug being scarce, electrargol was given to one case in the dose of thirty c. c. intravenously on two successive days, and in another two intravenous injections of 0.02 gram of mercury oxycyanide and one of 0.01 gram on successive days were administered, with results similar to those procured by the arsenical remedy.

Extensive Fibrosis of the Left Ventricle in a Child.—E. Parker Weber (*British Journal of Children's Diseases,* October, 1916) reports a child, ten years of age, in whom the principal symptom was hemorrhage from the bowel. The patient remained in the hospital for about three months and left in an apparently satisfactory condition, with the exception that there was an enlargement of the heart. Two and a half weeks later the patient was readmitted, complaining of a feeling of painful stiffness in the legs and abdomen. Five days later the pain became violent and the right foot was paler and colder than the left. This paleness gradually extended up to the groin and, at the end of about seven hours, the patient died. The autopsy showed a dilated and hypertrophied heart. The cavity of the left ventricle showed a soft, organized ante mortem thrombus firmly planted on the endocardium near the apex.

Diagnosis of Pneumonia.—J. Staige Davis (*Virginia Medical Semi-Monthly,* October 13, 1916) states that of forty-eight cases of lobar pneumonia recently under observation, nineteen were recorded as showing on admission no physical signs of the disease. In some cases no positive signs could be detected for several days, and in one or two Davis was never sure that any existed at any time. Thus it is often necessary in pneumonia to look for indications other than the conventional consolidation and rales. Chills were the initial symptom in twenty cases, and pain in eighteen, but several patients had repeated rigors and the pain was often in the epigastric, hypondriac, or iliac region, or even in the extremities. The typical single chill was at times replaced by a convulsion or by nausea, vomiting, or coughing. Blood spitting several times preceded consolidation. Weil's sign of defective subclavicular expansion on the affected side was sometimes of value. Dyspnea was once the first complaint. The temperature was often fluctuating rather than steady, despite textbook descriptions to the contrary. The best diagnostic sign, in Davis's opinion, is leucocytosis, which is higher, especially as regards polymorphonuclears, than in any other inflammatory disease. Over 30,000 of leucocytes, with eighty-one to ninety-two per cent. of polymorphonuclears, virtually excludes most other disorders. This rise could usually be detected by the second day in the writer's cases, and saved several patients sent in for supposed acute abdominal troubles from surgical intervention. Leucocytosis is also prognostic, its absence being of grave import. Its persistence after the crisis indicates a complication. Absence of eosinophiles is another ominous finding. Davis demurs to Gibson's statement that a fall in blood pressure, or a pulse rate over 140, is necessarily fatal. Assertions as to a diminution of the urinary chlorides also frequently proved erroneous. The x ray several times revealed an affected spot scarcely more than suspected by other means, and once not even considered. As Mason has stated, the shadow always touched the pleura and was triangular, with its apex toward the hilum. Consolidation is silent as long as relatively normal lung tissue intervenes between the affected area and the bronchi and trachea. Often the first sign is in the axilla. Blood cultures are troublesome and frequently negative. In cases of doubt between pneumonia and appendicitis in children the marked polymorphonuclear leucocytosis of the former proved of chief diagnostic value, and once or twice the x rays settled the decision. The same modes of investigation proved of paramount importance in the differentiation from subdiaphragmatic abscess, and are to be chiefly relied upon in excluding acute miliary tuberculosis, and peptic ulcer. In pleurisy with effusion in children, the usual history of the condition being secondary, the dislocation of the heart and the exploring needle, settle the question even in the encysted cases where mobile fluid cannot be detected.

Duodenal Cultures in Typhoid.—A. L. Garbat (*Journal A. M. A.,* November 18, 1916) states that the relative frequency of occurrence of typhoid carriers among apparently healthy persons, the high proportion of persons who have had typhoid, and who become carriers, and the very great frequency with which typhoid fever is traceable to contact with carriers, make it desirable to have some easy and efficient means of detecting carriers. The examination of the stools fulfills none of these conditions, even by the most elaborate precautions and the use of various special media. It has long been known that the gallbladder harbored the organism, and was the source from which it entered the intestine in carriers. Garbat has therefore attempted to make use of this fact by cultivating the bile, obtained from the duodenum through a duodenal tube. His technic is simple and is described in full. The cultures were made on ordinary media and little difficulty was encountered from overgrowth by other organisms, specially the colon bacillus. The method was tried in several cases convalescent from typhoid, and two of twelve showed the organisms in their bile for some time after recovery from the disease. In both of these cases the urine and stools were negative.

Complement Deviation in the Diagnosis of Hepatic Abscess.—L. Tribondeau and M. Fichet (*Bulletin de l'Académie de médecine,* October 10, 1916) report the preparation of an hepatic pus antigen by macerating the pus in distilled water in the ice box, decanting the supernatant fluid, and adding nine in 1,000 of sodium chloride. The corresponding antibodies are then sought in the serum of patients with hepatic abscess by the general Bordet-Gengou method of complement deviation, the natural hemolysins of the serum being used, as in Hecht's procedure. The sought for "pyodeviation of the complement" was manifested in six cases of liver abscess; negative results, in the other hand, were noted in healthy subjects, and in secondary syphilis. In amebic infection results were positive only where actual suppurative destruction of the liver was taking place. In catarrhal jaundice, and in Hanot's hypertrophic cirrhosis they were negative. In various chronic suppurations of structures other than the liver positive results were obtained, at times even after recovery; on the other hand, pus from localities other than the liver did not yield an active antigen. The hepatic pus perhaps owes its special properties to a more complete disintegration of the cells.

Treatment of Gonorrheal Ophthalmia.—A. N. Strouse (*Bulletin of the Department of Public Charities,* October, 1916) describes the use of protargol in the strength of from thirty to fifty per cent. The solution should be freshly prepared and distilled water should be used. The solution is best prepared by sprinkling the powder on the surface of the water and allowing it to dissolve. The applications are less painful than the weaker solutions of silver nitrate and the pain subsides rapidly under the usual treatment of ice pads and irrigations. There is some staining of the tissues, which disappears in a day or two.

Clinical Value of Complement Fixation in Tuberculosis.—H. R. Miller (*Journal A. M. A.,* Nov. 18, 1916) states that the specific diagnostic measures so far advocated for the determination of the presence of activity in tuberculous patients and suspects have all failed to differentiate between an infection at some previous time with the tubercle bacillus and an active lesion occurring at the time of the test. Many attempts have been made to employ some form of complement fixation test for this purpose, but these, too, have failed in the matter of differentiation between activity and latency. Recently the author, together with Zinsser, observed the apparently satisfactory results obtained from an antigen made by grinding dead or living tubercle bacilli with table salt and bringing the suspension up to isotonicity with distilled water. Miller has applied this test to over 1,000 persons, both tuberculous and nontuberculous. The results showed that the reaction was almost invariably positive in cases of active tuberculosis, and invariably negative in certainly nontuberculous persons, including syphilitics. The test was also usually negative in arrested cases of tuberculosis. By the test, in association with other diagnostic measures, the existence of a group of persons was discovered, who were apparently tubercle bacilli carriers with no evidence of active lesions and not reacting positively to the complement fixation test, but who excreted tubercle bacilli in their sputa. The von Pirquet and endermic tuberculin tests were found to be totally different procedures, since they failed to indicate activity, while the complement fixation test gave results in close dependence upon the presence and degree of activity.

Progressive Torsion Spasm of Childhood.—J. Ramsay Hunt (*Journal A. M. A.,* November 11, 1916) states that this affection, characterized by peculiar spasms, hypertonus, and hypotonus of the muscles of the trunk and extremities, and a series of twisting and torsion movements, has been recognized for only six years. The spasms are increased by activity and decreased by rest. Gait and station are mainly affected and the tendon reflexes are present, but difficult to elicit. Hunt reviews the reported cases and presents six personal observations. From all of these the facts brought out are that the affection is limited to childhood in its onset, occurs almost exclusively among Russian or Polish Jews, is progressive, and involves the sexes equally The lower extremities and lower part of the trunk are most frequently and extensively involved and the muscles supplied by the cranial nerves are never affected. Remissions and exacerbations are rare. There is characteristically a disturbance of harmony of muscular action with hypertonus of some and hypotonus of other muscles. Lordosis and crescent feet are usually present. There is a reversal of voluntary movement; thus an attempt to extend a flexed foot results in increased flexion and vice versa. Hunt regards the condition as due to some organic central nervous lesion situated below the corpus striatum, although the few cases which have come to autopsy have not revealed any organic lesion.

The Etiology of Scarlet Fever.—Mallory and Medlar (*Journal of Medical Research,* November, 1916) report their investigations, which although not conclusive are very suggestive. They found in the tonsillar tissue and throughout the respiratory tract a small Gram positive bacillus which occurs in dense masses, chiefly in the upper portion of the fibrinopurulent exudation covering the walls of the crypts. In the lung tissue some of the bronchioles and alveoli were completely filled with the organisms. Morphologically the bacillus is a little more slender than that of diphtheria. Its length varies considerably; it may be shorter or it may be longer than that organism. Filaments and branching forms are often seen, especially in lesions of the lung and bronchi. As a rule it stains solidly, but irregularity in staining is often observable. No polar bodies were seen at any time. It is also much more strongly Gram positive than the diphtheria bacillus The question comes up whether or not this organism is a secondary invader in scarlet fever as is the streptococcus. It was, however, found abundantly and extensively distributed in two early cases of scarlet fever, and was found in three other acute cases. A very important point is that it was found only in cases which had been scarlet fever. Control examination of tissues from over five hundred cases, mostly children, which came to autopsy in the contagious department following death from diphtheria, measles, pertussis, and varicella, failed to show it. Inasmuch as characteristic lesions were present in the tonsils after twenty-nine days the probabilities are that the discharge from the nose and ears are the sources of infection. For many years it was thought that the desquamating skin was the source of danger, but within recent years this view has been practically given up by experts in contagious diseases.

Studies on Treponema pallidum and Syphilis.—Zinsser, Hopkins, and McBurney (*Journal of Experimental Medicine,* November, 1916), in experimenting with cultures of treponema pallidum report that agglutination tests were not specific enough to be used for diagnostic purposes. They found that while the serums of syphilitic patients, especially those in the tertiary stage, agglutinate culture of treponema pallidum to slightly greater extent than do those of normal subjects, the serums of many subjects with diseases other than syphilis agglutinate it to an almost equal degree. They noted also that immunization with a culture of treponema pallidum, either local or general, does not seem to confer upon rabbits any considerable degree of resistance to inoculation with virulent treponemata.

Proceedings of National and Local Societies

ASSOCIATION OF AMERICAN PHYSICIANS.

Thirty-first Annual Meeting, Held at Washington, D. C., May 9, 10, and 11, 1916.

The President, Dr. Henry Sewell, in the Chair.

The Biochemistry of Acidosis.—Dr. Lawrence J. Henderson, of Boston, said that like heat equilibrium, the equilibrium between acids and bases was essential to life. Fluctuations in equilibrium occurred, but normally the limits of fluctuation were narrow. Wider fluctuations occurred pathologically, but the acid base fluctuations did not as a rule involve changes in the H ion concentration. Acidosis was defined as any disturbance of the acidbasic equilibrium whereby the power to resist acids in the body was lost. It was now possible to say that the main change in acidosis was the loss of blood bicarbonates. The bicarbonates were to be regarded as the *third* constituent of the blood; reckoning water first, salt second, and bicarbonate third. This third constituent was specially subject to fluctuations, owing to the constant physiochemical interchanges between blood and respired air; and since H ion concentration was proportional to the reactions between bicarbonates and free carbon dioxide, the ratio of free dioxide and bicarbonates was kept fairly constant by the mechanism of ventilation: hence H ion concentration was now regarded as the hormone of respiration. The maintenance of the acidbasic equilibrium became more complicated in pathological states, and always was related to, and dependent on the general metabolism of the body. Beneath all metabolism was a constant diminution of blood bicarbonates; unless repaired this led to acidosis.

The carbon dioxide tension of alveolar air and of the blood, together with the measure of alkali ingestion, were the measures of acidosis. Neither ammonia concentration nor urinary findings were safe guides.

Attempts to explain general pathological states on the basis of H ion concentration or acidosis were not justified. Any attempt to treat a disease like nephritis by the indiscriminate administration of large amounts of alkali was malpractice. Small amounts of alkali, given over a long time, were allowable, and when so given acidosis was impossible.

Acidosis in Infants and Children.—Dr. John Howland, of Baltimore, remarked that acidosis in children was a dangerous, but often an acute, self limited disease. It was not merely an acetonuria, but depended on a loss of the acidbasic equilibrium of the blood. Hyperpnea was the clinical sign: laboratory tests were the indices, these being carbon dioxide tension of alveolar air, H ion concentration of blood, and alkali reserve of blood. The natural low level of carbon dioxide tension and low H ion concentration in the young explained susceptibility to acidosis. Onset of acidosis was marked by hyperpnea; coma soon ensued; the alkali reserve might be restored, but unless this was done quickly, death followed. When acid phosphates were found in excess (five to fifteen times the normal) in the blood, and this condition was continued long enough, it would rob the body of bases. Restoration of bases did not always stop the accumulation of acid phosphates. Acidosis was seen in many diseases of infancy and childhood and should always be kept in mind; its early, rational treatment might be the means of saving life.

Acidosis in Diabetes.—Dr. R. T. Woodyatt, of Chicago, explained that the occurrence of acidosis in diabetics depended on the definition of the difference between the diabetic and the normal individual. The proportionality between glucose utilization and wastage depended on rate of intake. It might be said that with a rate of glucose intake high enough, the normal subject became diabetic; with the intake low enough, the diabetic acted like the normal subject. The difference was in the wastage. The occurrence of acidosis in diabetics depended on this; for it had been found that one molecule of carbohydrate must be burnt to care for three molecules of higher fatty acids; if this ratio could be maintained, the body "smoked" with unburnt fats, and acetone, betahydroxybutyric acid, and diacetic acid appeared in the urine.

In diabetics the absolute rate of carbohydrate utilization was low, and it was necessary to bend down the rates of protein and fat metabolism to meet that of the carbohydrates. Thus the application of rest, warmth, and fasting in the treatment of diabetes was rational. Acidosis in diabetes might always be accounted for in the way described, except in certain cases, e. g., its occurrence in the course of septic processes; such cases might be called accidental rather than diabetic acidosis.

Acidosis in Acute and Chronic Diseases.—Dr. Channing Frothingham, Jr., of Boston, said that the finding of acidosis in diseased states other than diabetes led to a study of carbon dioxide tension of alveolar air, H ion concentration of blood, acetone and ammonia nitrogen output in urine, and soda utilization in a large and diversified series of cases. The results of the study might be summarized thus: In adults, acidosis of the diabetic type did not exist in a large number of miscellaneous diseases, but a certain form of acidosis did exist (as shown by Howland) which might be recognized by available tests.

Investigations in Diagnosis and Treatment.—Dr. Leonard G. Rowntree, of Minneapolis, remarked that the H ion concentration of the blood must be kept at a normal level to maintain life. A method of measuring this factor was presented last year. Since then studies with the electrometric method had established the fact that the dialysis indicator method might be depended upon; the method was simple and absolute. Studies of the "buffer" values of the blood (ability to care for acidbasic fluctuations without disturbance of the H ion concentration) indicated the normal to be 0.36. In acidosis, the "buffer" value for both acids and bases was reduced or lost. The mechanism of changes in "buffer" value was not known. It might be said that true acidosis occurred when there was a change in

H ion concentration of the blood; compensated acidosis occurred when there was a change in the buffer value without change in H ion concentration. In disease states, acidosis and disturbances of H ion concentration might be corrected without benefit to the patient. The administration of alkalies beyond the point of correction of acidosis was harmful: alkali therapy, therefore, should be controlled by available tests.

Dr. Yandell Henderson, of New Haven, said it seemed to be the first duty of one attempting to summarize the papers here grouped under the general title, acidosis, to inquire if all the writers were talking about the same thing. It seemed to him they were not; the first paper, Doctor Henderson's, was a clear cut, scientific picture of a biological process; in the other papers, the writers were dealing with other things in addition. This was often the difficulty in the study of medical problems; they were in need of clear cut nomenclature. The acidosis they used to talk about was certainly not the acidosis of today. The acidosis of diabetes was not the acidosis of asphyxia, nor of nephritis. They might better in one case speak of ketonuria, and in another of low carbon dioxide states, and so on. In 1911 he had been a member of Haldane's Pike's Peak expedition, and all of the party had acidosis when a sufficient altitude was reached, if the carbon dioxide tension was taken as the index. He was rather skeptical of the hurtful effects of acidosis; for he had seen no figures which indicated a more severe acidosis than he persistently had himself on Pike's Peak when he was feeling particularly well.

The description given by Dr. Lawrence Henderson was on the basis of sea level data. But on going above sea level acidosis increased with the altitude; in a caisson acidosis diminished. Miss Fitzgerald, of the Haldane expedition, had shown this as a result of hundreds of observations made by her at various altitudes. The net result of her work was that one could determine the altitude of any community by the measure of the carbon dioxide tension of the alveolar air of the inhabitants, or, in other words, by their acidosis.

It seemed to him safer to keep in mind the facts: From the urinary standpoint, acetonuria might be found; from the respiratory standpoint, variations in carbon dioxide tension, or volume of ventilation might be measured; from the point of view of the blood, disturbances of H ion concentration might be noted; and other measures of the body's alkali acid balance might be made. But if all of these measures were to be accepted as measures of acidosis, they would meet with cases of acidosis, in which the acidosis was not a condition of acid blood at all, because the H ion concentration of the blood might still be normal. It was necessary, therefore, to formulate and keep clearly in mind just what in the future was to be known as acidosis.

Doctor Van Slyke, of New York, said that much of the discussion had dealt with the relations between the kidney, lung, and blood functions in acidosis. He and his coworkers had been much interested in these relations; and their observations had led them to conclude that the phenomena arising in these various systems were corollaries one to another. Indeed, he had been struck by the beautiful concord between the clinical and chemical facts, and the theoretical considerations advanced originally by Dr. Lawrence Henderson. He agreed with Henderson that acidosis was in fact a loss of the normal relationship between acids and the bicarbonates of the blood. He agreed also with Rowntree's classification of compensated acidosis and true acidosis on the basis of undisturbed and disturbed H ion concentration respectively.

With regard to reduction of carbon dioxide tension of alveolar air, this was only an indirect measure of the H ion concentration of the blood, and could not be regarded as synonymous with acidosis. It was an exact measure of the H ion state of the blood only when the lungs were functioning normally and under fixed conditions of temperature and atmosphere. The same might be said of the urinary findings: certain urinary changes were recognizable and acceptable as indirect evidences of acidosis; but they were not synonymous with acidosis, and depended upon renal integrity and other factors for constancy.

Dr. S. J. Meltzer, of New York, felt a great obligation to the president for the symposium and especially for inviting the Hendersons. There should be general appreciation of the lucidity and completeness of Lawrence Henderson's statement. This association should especially appreciate it, because another president had invited another man who came with the statement that all ills were due to acid, but all ills might be cured by alkalies. Doctor Henderson's clear cut statement atoned for this; under his simple exposition the mode of origin of the two blood factors, acidosis and alkalosis, became intelligible, and that they could not be causes of any specific disease state, becomes obvious.

Dr. Theodore C. Janeway, of Baltimore, wished to discuss the subject on a sea level basis; he would not seek to attain the altitude of Dr. Yandell Henderson's remarks. The discussion had been valuable for clearing the views of clinicians and pathologists alike. Thus far they had talked of acidosis in terms of ketonuria; but it had now been shown that the modern conception of acidosis, acidosis in its strict sense, was the true cause of diabetic coma. Most of the criticisms had been based on the fact that acidosis was merely a biochemical event and not a just measure of disease; but it was the acidosis that caused the hyperpnea, etc., and it was possible to conceive of acidosis as the cause of functional disturbances without sacrificing the truth of Lawrence Henderson's remark about the nonspecificity of the blood changes in this condition. The newer types of acidosis had to be recognized: it was only necessary to remember that there were fundamental metabolic differences in the origins of the various types.

Dr. E. P. Joslin, of Boston, acknowledged his debt to Doctor Henderson for the simplicity of his exposition. He referred also to the clarity of Doctor Woodyatt's exposition of the dependence of the acidosis of diabetes on defective utilization of carbohydrates. Two thirds of all diabetics died in coma; and all diabetic children. All diabetics dying in the first year of the disease, died of coma. If it

could be shown that the number of diabetic fatalities in the first year of the disease had been lessened, this must be because the treatment of acidosis had improved with the improved treatment of diabetes. Such statistics were now available and showed that the mortality of diabetes in the first year had been greatly reduced. Clinicians could congratulate themselves on this distinct advance in the treatment of a difficult disease.

(*To be continued.*)

AMERICAN LARYNGOLOGICAL ASSOCIATION.

Thirty-eighth Annual Congress Held at Washington, D. C., May 9, 10, and 11, 1916.

The President, Dr. G. Hudson-Makuen, in the Chair.

(*Concluded from page 1025.*)

Epithelioma of Posterior Pharyngeal Wall Cured with the Electrocautery.—Dr. Dunbar Roy, of Atlanta, had a case of a female, aged twenty-seven years, first seen July 29, 1913. Previous and family history negative. Present history: For last three months had suffered with a soreness and throbbing in her throat. Had been treated continuously without result. Examination showed a rounded ulcer on the posterior pharyngeal wall at centre, one half of which was hidden by the soft palate; dirty gray in appearance, with edges sharply defined; about one half inch in diameter, and extending as deep as the superficial aponeurosis. A piece excised showed it be an epithelioma. Removed by means of the electrocautery point, well outside of its edges. No reaction and no discomfort followed. Healing perfect under one application. After three years there were no signs of a return. Unfortunately, clinical observers were too prone to classify malignant growths of the throat under the general term cancer, without distinguishing between the different forms of carcinoma and sarcoma. This statement was made because the writer had found it almost impossible to correlate all cases recorded, in that many of them were reported in the most unexpected places, and not under the headings where one would expect to find them. As Morell McKenzie and others had pointed out, the disease was often so extensive when first examined that it was impossible to tell its point of origin. Textbooks were vague in the discussion of this subject. It had now been three years since the case here reported had been healed, and there had been absolutely no signs of a recurrence. The results obtained in one case, especially of the cancerous type, certainly did not justify any positive deduction, but the speaker believed that the thorough and judicious use of the electrocautery offered the best chance for a good result.

Dr. J. Solis Cohen, of Philadelphia, had been glad to hear the paper by Doctor Roy, because it exemplified the opinion that epithelioma, taken early, before there was any glandular involvement, could be cured. The method which he adopted was an excellent one. In the first place, he eliminated the growth, and a certain portion of healthy tissue around it, with the cautery. The heat of the cautery extended and cooked some of the area around that growth, and entirely getting rid of the growth, he of course had a normal return of tissue. He got rid of the entire growth except as far as the scar tissue was concerned.

Dr. Cornelius G. Coakley, of New York, thought the case of Doctor Roy exceedingly interesting. It presented one phase, however, to his mind, which was little doubtful, and that was, that he understood the specimen was examined only in frozen section. He thought most pathologists would feel a little bit in doubt as to their examination of a frozen section. The next point was the unusual absence of glandular involvement in this area. He had never seen a malignant process, even fairly early, on the posterior pharyngeal wall, that did not have the glands involved. It might have been some particular type of cancer—some peculiar form, different from the average type which they ordinarily saw. The next point was one which they ought to take up seriously, and that was the absence in the literature of records of cases of involvement of the nose, throat, accessory sinuses, pharynx, and larynx. Within the last year he personally ran across at least one dozen cases of malignant disease of rather unusual type—ethmoidal, maxillary, etc. He had one case recently involving the sphenoid and nasopharynx—whether primary or secondary, he could not tell. Those cases were unrecorded in the literature, and he had no doubt that those who were working in large clinics had numbers of these cases. He thought they should report all cases of malignancy seen during the year and have them tabulated in some form for reference. It was really surprising to note the relative frequency of these cases compared with the actual records.

Dr. D. Bryson Delavan, of New York, said there was nothing so uncertain about the prognosis in a case of so called epithelioma. When the microscopic examination was made and the findings were reported, there their information ended. There were in the recollection of most of them isolated cases which differed entirely in their result from the average. For example, the solitary case in which Doctor Elsberg operated at different times for a dozen years, and in which Doctor Cohen operated twenty years after its inception, and the patient lived fifty years after the first operation. That was a long while for a patient to survive epithelioma. In contrast he had an epithelioma of the epiglottis which was discovered so early that the growth was only about half the size of a split pea, one quarter of an inch in diameter, on the extreme margin of the epiglottis. One third of the epiglottis was thoroughly removed, as far down as possible, and the disease completely extirpated. After four or five years there was a healthy mass there, and then the patient relapsed and died.

Extensive Cholesteatoma Following the Luc-Caldwell and Killian Operations, Simulating Sarcoma.—Dr. Virginius Dabney, of Washington, D. C., had a case of a man, forty-two years of age, who gave no subjective symptoms of his grave condition other than nasal stoppage. He had exophthalmos, complete deviation of septum, polyps in middle strait with acute exacerbation three days

later. Luc-Caldwell operation performed and extensive exenteration of ethmoid bone, with subsidence of symptoms. Five days after this, symptoms returned, and Killian operation was done, with perfect functional and cosmetic results. Eleven days later, abscess in cheek formed and was evacuated by incision below and parallel to the lower eyelid. Great distention of cheek, frequent spontaneous hemorrhages, convincing radiographs and wooden hardness of mass in cheek suggested sarcoma. Two months later, operation revealed immense collection of true cholesteatoma; odor overpowering; all bone above, below and on each side of mass eroded and totally destroyed, including floor and inner wall of orbit, two thirds of malar bone and all of outer wall of antrum. Present condition of patient, marked asthenia; death only matter of short time. Syphilis, tuberculosis, malignancy all excluded by proper methods.

Letters to the Editors

AS TO THE ORIGIN OF LIFE.

New York, *November 24, 1916.*

To the Editors:

Your editorial article on the Origin of Life has interested me considerably. While there is little doubt that new combinations of energy are being constantly constructed, witness the incessant polymerization of the starch molecule through the enzyme action within the chlorophyll grain, whereby the sun's energy is being condensed and transformed into carbohydrates, still some of your illustrations are not happily chosen.

I refer to your statement with reference to the origin of the organism causing poliomyelitis where the editorial article states that "poliomyelitis seems hardly to have been known before 1840." Why, in 1840, Heine had written his important monograph on the disease with a fully elaborated orthopedic therapy. Underwood, in 1784, gave excellent descriptions, and called it a new disease. In the writings of the authors of the sixteenth, fifteenth, and fourteenth centuries it is apparent. Hieronymus Bosch has given us, in the fifteenth century masterly pictures of all of the chief types of deformities due to the disease. Statuettes of the club feet and other dwarfing processes are known from the Roman, Greek, and even Egyptian times, and the typical bony deformities are known from Egyptian mummies of the middle dynasties, circa 2000 B. C. Certainly this evidence which is but a tithe of what is known would nullify the value of the statement quoted.

There is plenty of evidence to show the active formation of new energy combinations, but even Bastian's most cherished experiments on the spontaneous formation of microorganisms still remain not proven.

Smith Ely Jelliffe, M. D.

THE END OF THE POLIOMYELITIS EPIDEMIC.

New York, *November 21, 1916.*

To the Editors:

I wish to call attention to the fact that with the advent of frost all over the country, from Maine to California, and the death of the mosquito consequent thereto, the cases of infantile paralysis stopped at once, just as yellow fever stopped on the same occasion. The reason is the death of the active carrier, the mosquito; certainly the frost does not kill the paralysis germ carried in the mouth, adenoids, and tonsils of human beings as stated by the experts. I have also failed to hear of any expert trying to transmit the disease from human babies to baby monkeys, not adult ones, for the adult monkeys are as immune from the disease as are adults of the human race. I have just seen the prospectus of a book on infantile paralysis written by eminent medical men, and every fly and biting insect is discussed therein, with the exception of the mosquito.

Charles S. Braddock, Jr., M. D.

Book Reviews

[*We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.*]

Clinical Disorders of the Heart Beat. A Handbook for Practitioners and Students. By Thomas Lewis, M. D., D. Sc., F. R. C. P., Assistant Physician and Lecturer in Cardiac Pathology, University College Hospital, Physicians to Out Patients, City of London Hospital for Diseases of the Chest. Third Edition. New York: Paul P. Hoeber, 1916. Pp. xii-116. (Price, $2.)

The first edition of this valuable book was issued in 1912. The rapid exhaustion of the first and second editions has resulted in preservation of it for the most part in its original form in this new, third edition. The chief change is an additional chapter on the most recently discovered form of cardiac arrhythmia, viz., auricular flutter, which is to be carefully distinguished from auricular fibrillation, with its confusingly similar name. Whereas in the latter coordinate contraction of the auricle is lost, auricular flutter is defined by Lewis as a condition in which the auricular beats are submerged by contractions in response to a series of new, pathological, yet rhythmical impulses varying in rate from 200 to 350 a minute. The flutter is as yet so new a condition that the author is unable to speak very definitely of its prognosis. The strength of the heart muscle and the burden it has to carry in the individual case, however, supply a partial basis for a prognosis, and fortunately the condition is readily amenable to digitalis or strophanthus treatment. Heart block, it is now pointed out, among infectious diseases is limited to the more severe cases. In the chapter on auricular fibrillation, a paragraph has been added calling attention to the favoring influence of this condition on ante mortem clotting in the auricles; this is evidently due to the virtual paralysis of the auricles occasioned by the disorder and the consequent stagnation of blood in them during life. Embolism of the lung and brain has been observed by Lewis where previously fibrillating auricles have resumed normal contractions. The book in its new form is again to be warmly recommended to the practitioner as affording a simple, concise presentation of the clinical aspects of the arrhythmias, in the discovery and development of which the author has himself played so important a part.

The American Year-Book of Anesthesia and Analgesia. F. H. McMechan, A. M., M. D., Editor. 1915. New York: Surgery Publishing Company, 1916. Pp. ix-416. (Price, $4.)

The publication of this, the first edition of the year book, indicates that anesthesia and analgesia are taking a place with the other specialties. Previous to the publication of this volume the advances in these branches were recorded in the quarterly supplement to the *American Journal of Surgery*. The book contains 420 pages of reading matter which cover, not only the science and theory of anesthesia and analgesia, but the practical sides of these subjects as well. The foremost dentists, physicians, surgeons, and laboratory workers have collaborated in making this volume a veritable masterpiece. Some of the articles are from the most prominent laboratories in the country. It had been intended to include within its pages the work of authorities other than American, but owing to the struggle raging in Europe, this, unfortunately, could not be done. Several of the subjects have been gone into at length, and these will be kept up to date in subsequent issues.

The book is beautifully finished in art buckram, is printed on India tint paper, and contains 250 illustrations. The amount of subject matter is so voluminous that the benefit derived from reading it can be fairly compared with that obtained by taking a postgraduate course in anesthesia and analgesia.

The editor has thoughtfully introduced a frontispiece to the book, which with the following inscription, may become historical: "James Taylor Gwathmey, M. D., and Charles Baskerville, Ph. D., F. C. S., in the latter's laboratory of the College of the City of New York, discussing the experimental details which resulted in standardizing the rate of the evaporation of ether oil solutions in the technic of colonic anesthesia."

Le Système Taylor et la physiologie du travail professionnel. Par J. M. Lahy, Chef des travaux au laboratoire de psychologie expérimentale de l'Ecole pratique des Hautes Etudes. Paris: Masson & Cie., 1916. Pp. x-198.

This book is essentially a painstaking analysis, by an experimental psychologist of the F. W. Taylor method of scientific factory organization—a method having for its purpose so to adjust mutually the workman and his work that the greatest possible efficiency and rapidity of production shall result. The author's criticisms of Taylor's system are by no means uniformly favorable. Its sponsor is reproached with having reduced the workman too much to a mere machine, with interfering indirectly with his general social activities, and with overlooking the fact that, machinery gradually being substituted more and more for human action, the capacity for attentive supervision and prompt, certain adaptation to new problems must be preserved. A number of technical criticisms of Taylor's methods are also advanced. His system is deemed insufficient from the standpoint of physical fatigue in workers who are not called upon to put forth any pronounced muscular effort. In a general way, however, the method is commended as tending to draw attention to the value of order where before many things were in confusion. In the final chapter the author describes how, in his belief, the best of Taylor's principles may be applied, and how they may be supplemented by others to the greatest advantage.

Interclinical Notes

In an editorial discussion of the narcotic habit among boys, the *Sun* for November 22d eliminates the final e from heroine, while retaining it in morphine and cocaine, thus bedeviling still further a problem in medical spelling. We confess to inability to follow the *Sun's* rule, if it has one, as all three drugs are alkaloids.

* * *

A novel view of the aeroplane appears in *Leslie's* for November 9th, wherein Mr. Glen L. Martin, one of the pioneer aviators, is quoted as saying that "there is no means of transportation yet devised that will make sixty miles an hour as safely as an aeroplane."

* * *

Edward T. Devine, in the *Survey* for November 18th, states that although we are impartial between the belligerents in the present war, we shall not be impartial between any future disturber of the peace and the peacemakers; in the establishment of a secure and lasting peace we have a decided interest backed by a reasonable measure of moral force, capable of expression in terms of physical force if that should prove to be necessary and appropriate.

* * *

Apparently few residents of the greater city of New York know much about the Brooklyn Institute of Arts and Sciences, an admirable organization for postgraduate study—in many instances, indeed, undergraduate instruction—of which Brooklynites are very proud. The students or members have the opportunity to hear at lowered prices the greatest musicians, soloists, or chorus or orchestra members, speakers and readers such as Sir Rabindranath Tagore, Colonel Roosevelt, and Mr. Taft, and to enjoy without other expense than a small membership fee, the study of domestic science, zoology, philology, fine arts, astronomy, geography, dramatic art, music, photography, political science, chess, or chemistry.

* * *

The far reaching influence of the Brooklyn institute is shown by the lecture on the Public Health Service given by one of its surgeons, Dr. C. H. Lavinder, on November 25th. On the 22d, Dr. Simon Flexner lectured on infantile paralysis. On November 29th, there was a meeting of the Red Cross at the Academy of Music, the attendance being made up largely of persons who belong both to the Red Cross and the institute. The chief executive of the former spoke on the great war. On December 5th, Mr. Thomas Mott Osborne speaks on the Psychology of the Criminal. Dr. Eliza Mosher, author of a recent paper in the Journal, lectured on November 27th on the relation of posture to health.

In his paper on the Psychology of Wish Fulfilment in the *Scientific Monthly* for November, 1916, Professor John B. Watson, of Johns Hopkins University, emits an epigram that may sting severely such opponents of Freud as find the latter's theories immoral or "nasty." Speaking of the slips of tongue and pen which betray our secret and usually well guarded wishes, as well as of the dreams in which these wishes find fulfilment, Professor Watson remarks: "When the doctrine was first advanced, it raised a storm of opposition, not only from the staid, home loving, everyday men and women, but from scientific men as well." Now for it: "Objection to the view seems to stand in almost direct ratio to the amount of repression the individual possesses." Can it be that the noisiest anti-Freudians are in the same class as reformed drunkards and drug victims, who are always the most anxious that alcohol and narcotics should be universally prohibited?

* * *

According to the *Outlook* for November 29, 1916, Victor Kennard, formerly a great Harvard football star, when asked what football had done for him, made the following reply: "I learned to control my temper, to exercise judgment, to think quickly, and act decisively. I learned the meaning of discipline, to take orders and carry them out to the best of my ability without asking why. I had, through the training, regular habits knocked into me. I learned to meet, know, and size up men. I learned to smile when I was the most discouraged fellow in this great wide world, the importance of being on time, a better control of my nerves, and to demand the respect of fellow players. I learned to work out problems for myself, and to apply my energy more intelligently—to stick by the ship. I secured a wide friendship which money can't buy." This would not be a bad record for the influence on character of the whole university curriculum. If football can do all that Mr. Kennard believes it can, why waste time on the humanities, the fine arts, mathematics, and other *impedimenta* of the academic course?

Meetings of Local Medical Societies

Monday, *December 4th.*—Clinical Society of New York Throat, Nose, and Lung Hospital; German Medical Society of the City of New York (annual); Utica Medical Library Association; Niagara Falls Academy of Medicine; Brooklyn Hospital Club; Hornell Medical and Surgical Association; Clinical Society of the New York Polyclinic Medical School and Hospital; West Side Physicians' Economic League.

Tuesday, *December 5th.*—New York Academy of Medicine (Section in Dermatology); New York Neurological Society; Amsterdam City Medical Society; Lockport Academy of Medicine; Society of Alumni of Lebanon Hospital, New York (annual); Syracuse Academy of Medicine (annual); Buffalo Academy of Medicine; Ogdensburg Medical Association; Oswego Academy of Medicine; Medical Association of Troy and Vicinity; Medical Society of the County of Yates; Medical Society of the County of Ulster (annual); Medical Society of the County of Tioga (annual); Medical Society of the County of Orange (annual).

Wednesday, *December 6th.*—New York Urological Society; Brooklyn Society for Neurology (annual); Society of Alumni of Bellevue Hospital; Harlem Medical Association; Bronx Medical Association (annual); Elmira Academy of Medicine (annual); Society of Alumni of St. John's Hospital, Brooklyn; Schenectady Academy of Medicine; County of Rockland Medical Society (annual); Long Island Society of Anesthetists.

Thursday, *December 7th.*—New York Academy of Medicine; Brooklyn Surgical Society; Practitioners' Club, Buffalo; Geneva Medical Society.

Friday, *December 8th.*—New York Academy of Medicine (Section in Otology); Society of Ex-Interns of the German Hospital in Brooklyn; Flatbush Medical Society, Brooklyn; Eastern Medical Society of the City of New York (annual); Clinical Society of the German Hospital and Dispensary; Manhattan Dermatological Society.

Official News

United States Public Health Service:

Official list of changes in the stations and duties of commissioned and other officers of the United States Public Health Service for the seven days ending November 22, 1916.

Armstrong, Charles, Assistant Surgeon. Relieved from duty on the Coast Guard cutter *Itasca* and ordered to report for duty on Coast Guard cutter *Seneca*.

Baughman, D. S., Assistant Surgeon. Bureau orders dated October 14, 1916, revoked.

Billings, W. C., Surgeon. Granted seven days' leave of absence on account of sickness from November 23, 1916.

Brooks, S. D., Senior Surgeon. Bureau letter dated November 7, 1916, amended to grant five days' leave of absence from November 1, 1916.

Grubbs, S. B., Surgeon. Granted sixteen days' additional leave of absence from November 20, 1916.

Howard, A. R., Scientific Assistant. Directed to proceed to the establishments of the General Chemical Co. and make studies of occupational diseases.

Hurley, J. R., Passed Assistant Surgeon. Detailed to instruct first aid classes in the School for Preparedness during November and December, 1916.

King, W. W., Surgeon. Granted one month's leave of absence from December 21, 1916.

Mullan, E. H., Passed Assistant Surgeon. Granted twenty-one days' leave of absence from December 1, 1916.

Pierce, C. C., Senior Surgeon. Granted six days' leave of absence from November 7, 1916, on account of sickness.

Treadway, W. L., Assistant Surgeon. Directed to proceed to Nassau County, L. I., for duty in connection with a sanitary survey of schools

Turnipseed, D. C., Passed Assistant Surgeon. Granted two months' leave of absence from December 14, 1916.

Yarbrough, H. C., Assistant Surgeon. Granted ten days' leave of absence en route to Chicago.

Woods, E. O., Assistant Surgeon. Relieved at Seattle from duty and will report to the commanding officer of the Coast Guard cutter *Unalga* for duty.

Boards Convened.

Surgeons C. H. Gardner and J. M. Holt detailed as members of a Coast Guard Retiring Board, which met at the Marine Hospital, Buffalo, N. Y. November 27, 1916.

Boards of medical officers convened November 22, 1916, for the examination of Coast Guard officers for promotion, as follows: Baltimore: Detail for the board, Surgeon C. W. Vogel and Assistant Surgeon J. D. Reichard; Seattle, Wash., Surgeon B. J. Lloyd and Passed Assistant Surgeon E. Krulish; Astoria, Ore., Surgeon H. G. Ebert and Acting Assistant Surgeon J. Tuttle; Boston, Mass., Passed Assistant Surgeons W. M. Bryan and R. A. Kearny; San Francisco, Cal., Assistant Surgeons D. S. Baughman and J. F. Worley.

United States Navy Intelligence:

Official list of changes in the stations and duties of officers serving in the Medical Corps of the United States Navy for the three weeks ending November 18, 1916:

Ames, M. H., Surgeon. Detached from the *Salem* and ordered to the *Maine*.

Clifford, A. B., Passed Assistant Surgeon. Detached from the *Washington* and ordered to the *Virginia* for duty.

Donelson, M., Passed Assistant Surgeon. Detached from duty on the receiving ship at Norfolk, Va., and ordered to the *Pennsylvania* for duty.

Dragoo, C., Passed Assistant Surgeon. Detached from the Naval Hospital at Newport, R. I., and ordered to the Naval Training Station at Newport, R. I.

Farwell, W. G., Passed Assistant Surgeon. Detached from the *Culgoa* and will await orders.

Freeman, G. F., Surgeon. Ordered to the Naval Hospital at Boston, Mass., for duty.

Henry, R. E., Surgeon. Ordered to the Naval Training Station at Norfolk, Va., for duty.

May, H. A., Passed Assistant Surgeon. Ordered to the Naval Hospital, Annapolis, Md., for duty.

McLean, N. T., Passed Assistant Surgeon. Ordered to report at Washington, D. C., for promotion.

Mink, O. J., Passed Assistant Surgeon. Ordered to the *Columbia* for duty.

Plummer, T. W., Surgeon. Detached from the *Alabama* and ordered to the *North Dakota*.

Porter, F. L., Passed Assistant Surgeon. Detached from the *San Francisco* and ordered to Washington, D. C., to await orders.

Rhoades, G. C., Passed Assistant Surgeon. Detached from the Naval Hospital, Norfolk, Va., and ordered to the *San Francisco* for duty.

Sheehan, R. F., Passed Assistant Surgeon. Detached from the Naval Medical School and ordered to the *Culgoa* for duty.

Shepard, G. W., Passed Assistant Surgeon. Detached from the Norfolk Receiving Ship and ordered to the Training Station at St. Helena, Va.

Stalnaker, P. R., Passed Assistant Surgeon. Detached from the *Columbia* and ordered home to await orders.

Tribou, H. A., Assistant Surgeon. Detached from the *Virginia* and ordered to the *Tacoma* for duty.

Wentzel, W. S., Assistant Surgeon. Resignation accepted, to take effect November 8, 1916.

Wickersham, W. W., Assistant Surgeon. Detached from the *Prairie* and ordered to duty with the Marine Expeditionary Forces at San Domingo, D. R.

Ziegler, J. G., Passed Assistant Surgeon. Detached from the Coast Torpedo Force, Pacific Fleet, and ordered to the *Chattanooga* for duty.

Births, Marriages, and Deaths

Died.

Bailey.—In Dayton, Ohio, on Tuesday, November 14th, Dr. Jesse K. Bailey, aged sixty-five years.

Beith.—In Bowmanville, Ont., on Friday, November 10th, Dr. Alexander Beith, aged seventy-six years.

Boam.—In Topeka, Kan., on Wednesday, November 15th, Dr. Silas A. Boam, aged seventy years.

Breakell.—In Cross River, N. Y., on Saturday, November 18th, Dr. James A. Breakell, aged sixty-six years.

Claytor.—In Bedford City, Va., on Thursday, November 16th, Dr. David Mitchell Claytor, aged eighty-four years.

Darrow.—In Aurora, Minn., on Sunday, November 12th, Dr. Edward Darrow, aged forty-two years.

Dunn.—In New York, N. Y., on Thursday, November 23rd, Dr. T. Joseph Dunn, aged fifty-two years.

Faris.—In Sacramento, Cal., on Thursday, November 16th, Dr. Clifton Maupin Faris, aged thirty-eight years.

Grady.—In Natchez, Miss., on Monday, November 13th, Dr. John I. Grady, aged thirty-eight years.

Hermany.—In Mahanoy City, Pa., on Saturday, November 18th, Dr. Phaon Hermany, aged seventy-six years.

Johnstone.—In Reno, Nev., on Thursday, November 9th, Dr. Oscar Percy Johnstone, aged forty-five years.

Kenney.—In Providence, R. I., on Sunday, November 19th, Dr. William F Kenney, aged sixty-three years.

Kerr.—In Corsicana, Tex., on Sunday, November 12th, Dr. William J. W. Kerr, aged eighty-two years.

Maguire.—In Dubuque, Iowa, on Wednesday, November 8th, Dr. John E. Maguire, aged forty-six years.

Mayer.—In Willow Street, Pa., on Monday, November 13th, Dr. Isaac H. Mayer, aged seventy-two years.

Norris.—In New York, N. Y., on Sunday, November 19th, Dr. Henry Selden Norris, aged sixty-eight years.

Sanborn.—In Spencer, Mass., on Monday, November 20th, Dr. Frederick J. Sanborn, aged fifty-five years.

Schwagmeyer.—In Clifton, Ohio, on Saturday, November 11th, Dr. August W. Schwagmeyer, aged seventy-two years.

Sutton.—In Kansas City, Mo., on Friday, November 10th, Dr. Walter S. Sutton, aged thirty-nine years.

Varno.—In Thompsonville, Conn., on Saturday, November 18th, Dr. Henry G. Varno, aged sixty-six years.

Walker.—In Carnegie, Pa., on Sunday, November 10th, Dr. Robert Latshaw Walker, aged seventy-nine years.

GONORRHEA A CURABLE SCOURGE.

BY GEORGE A. WYETH, M. D.,
New York.

The title of this paper is chosen advisedly: Gonorrhea is a curable scourge. The modern means at the command of the physician are so definite and precise that it is inexcusable for a case of gonorrhea to remain uncured.

I do not suggest that it is always a simple and an easy thing to fight the gonococcus. Painstaking care in diagnosis, and definite location of the lesion are possible only by the microscope and the urethroscope. It is a fortunate thing for gonorrheics, and for society in general, that the day of haphazard treatment of all urethral infections is drawing to an end. That form of optimism which led the practitioner to employ only internal medication or perfunctory injections, and to discharge as cured patients whose condition demanded a further and more penetrating treatment, has worked incalculable harm and hardship.

Until a short time ago, both profession and laity joined in considering gonorrhea an unimportant affection. The seriousness of syphilis was early recognized, but it is only recently that we have appreciated the gravity of uncured gonorrhea and the horrors of its sequelæ. It is indeed gratifying to find leading journals like the *Times*, *Tribune*, and *Globe* occasionally lending their columns to the fight against these diseases, for only by education can headway against them be made. Once remove the veil of secrecy and shame under which the gonococcus thrives and it will perish. Mr. A. Foerster, of London, writes:

> It is being more and more realized that the fact of contracting a venereal disease is purely and simply a misfortune—and it seems timely to bring the principal member gonorrhea, to the front. There can be no doubt that its victims deserve our fullest sympathy, and they require the same care and attention as patients suffering from other diseases, were it only for the sake of their surroundings and their offspring. Our medicosurgical measures are excellent and practically guarantee a cure. They appear, however, to be inadequately known, and even among medical men a certain uncertainty appears to exist, so far as the treatment of gonorrhea is concerned.

An experience of many years in the study and treatment of this interesting disease has taught me the surpassing value of certain remedies, and their superiority over others which formerly were considered effectual The fact that gonorrhea—a preventable and curable disease—continues to scourge humanity is justification enough for a further presentation of the modern scientific means of eradicating it. As to its frequency and cost to social economy, I refrain from quoting statistics, for I believe few are reliable and many are the products of enthusiasts. So conservative a writer as Professor Osler, however, has written:

> Gonorrhea, one of the most widespread and serious of infectious diseases, presents many features for consideration. As a cause of ill health and disability, the gonococcus occupies a position of very first rank among its fellows. While the local lesion is too often thought to be trifling, in its singular obstinacy, in the possibilities of permanent sexual damage to the individual himself, and still more in the "grisly troop" which may follow in its train, gonorrheal infection does not fall very short of syphilis in importance.

Gonorrhea is a *preventable* disease, as has been amply proved in the U. S. Navy.

Gonorrhea *can be aborted* in the majority of cases if seen within twenty-four hours after a purulent discharge has begun, except in primary cases.

Gonorrhea *is a curable* disease.

Notwithstanding all this, gonorrhea is our most prevalent disease. So numerous are the innocent women invalided and robbed of motherhood, so numerous the babies blinded at birth, so numerous the crippled men and the ruined homes, as a result of its ravages, I incline to the opinion that gonorrhea is our greatest hidden peril.

Generally speaking, gonorrhea begins as an acute and usually ends as a subacute or chronic process. Nature at first makes a great effort to rid herself of the offending organism (profuse discharge), but eventually comes to tolerate its presence under mild protest. After a variable period, determined by the virulence of the infection, the resistive power of the patient, and the treatment applied, the acute stage begins to decline. It is not the purpose of this paper to treat of acute gonorrhea. For the treatment of this condition the reader is referred to the NEW YORK MEDICAL JOURNAL for February 5, 1916. In the subacute stage the number of gonococci has greatly decreased; phagocytosis is less marked; the embryonic infiltrations are being absorbed; the vascular changes are less conspicuous, and the destroyed epithelium is being regenerated. The process of repair has set in, and in a certain proportion of cases goes on to a happy termination. Unfortunately, this happy ending is not the

rule. Gonococci remain hidden somewhere in the tissues, and it is incumbent upon the physician. first, to determine their exact site; second, to eradicate them; and, third, to bring about a restitution of the tissues. Acute gonorrhea is a more or less diffuse process, but chronic gonorrhea is always localized to one or more areas, so that the matter of definite location is not a difficult one. All chronic gonorrheas are either anterior, posterior, or both, according to

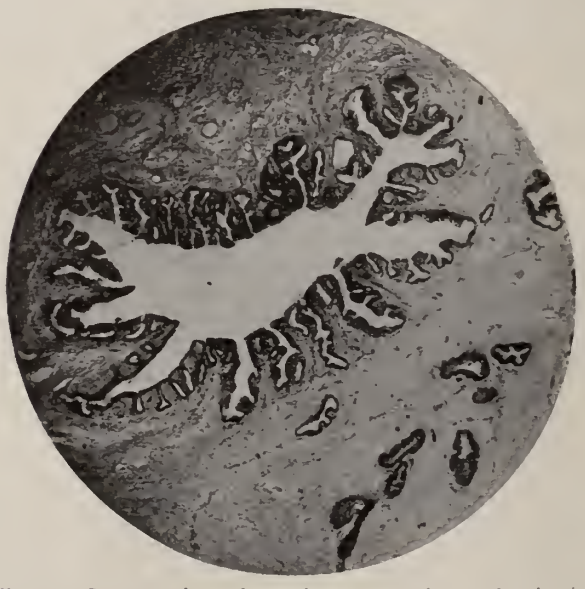

Fig. 1.—Cross section of membranous urethra x28, showing abundance of glands—many being deep seated.

whether the pathological process is situated in front or behind the anterior layer of the triangular ligament.

If posterior, it generally means an involvement of the prostate (rarely the seminal vesicles, in my experience), and I believe the membranous urethra is much more frequently involved than is commonly believed. Here glands are abundant. Many are deep seated and extend into the depth of the tissues as shown by cross sectioning. (Fig. 1.) To determine if the prostate is involved, little reliance is placed upon the "two glass test" but the patient is instructed to urinate into three glasses and the bladder is irrigated with 0.25 or 0.5 per cent. protargol solution. The prostate is then massaged and prostatic fluid expressed on a slide, fixed, stained, and examined under the microscope. If the prostate is found diseased, systematic, gentle massage is instituted, always irrigating before and after, and controlled by the microscope. This is continued until a liberal supply of lecithin bodies are returned, absolutely no gonococci are found on many examinations, and only three or four pus cells (not epithelial cells) to the field are found in the prostatic secretion. Gentle massage, moving the forefinger only, generally suffices to clear up this condition. Stubborn cases are assisted by the rectal psychrophore, hot rectal irrigations, hot perineal applications, vaccines, general tonics, and out of door life.

If anterior, the lesion is usually situated in or about the glands of Littré, and Morgagni's lacunæ. These are the great harboring places in chronic gonorrhea, and are, in my opinion, largely responsible for the widespread distribution of this disease (Fig. 2). Here gonococci may persist for years in spite of treatment. There are three predominant pathological processes common to the urethra when chronically inflamed, namely, infiltration of embryonic tissue cells, changes in the epithelium, and changes in the glandular tissue. The proliferation of embryonic elements goes on to connective tissue formation. This in time cicatrizes with stenosis, so that all neglected cases of chronic gonorrhea are invariably followed by stricture. Particularly is this true of the membranous urethra which is surrounded by the cut off muscle, which by its strong contractions fissures the mucosa and accounts for the frequency of stricture in this region. The epithelium as it regenerates is never restored as normal cylindrical epithelium, but always as numerous layers of flat, keratinized epithelial cells. The mucosa thus loses its elasticity and permeability to a marked degree, so that it is practically impermeable to injections. The glands may atrophy, form polypi, become occluded with the formation of small cysts or periurethral abscesses with fistulæ, or they may become hyperactive with a continual outpouring of mucus which may or may not contain gonococci. The microscope must determine this fact before we institute treatment, for here the pathway divides and he who aspires to cure gonorrhea should possess a knowledge of bacteriology which will enable him definitely to determine this fundamental factor.

Should the prostatic secretion prove free of infection and the anterior condition persist, local treatment is begun to destroy the gonococci which have been harbored in the glands and lacunæ, to cause an absorption of the round cell infiltration, and to restore the mucous membrane to as near normal as possible. This is best accomplished by means of the Frank modification of the Kollmann dilator, which is

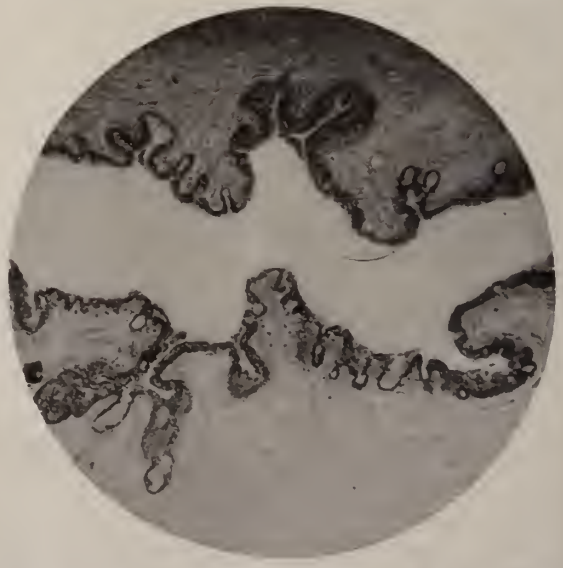

Fig. 2.—Cross section of anterior urethra x30, showing Morgagni's lacunæ and glands of Littré.

an anterior, irrigating dilator with three prongs instead of four. It has an irrigating attachment with holes in the shaft of the instrument to allow the inflow of fluid, and an outlet to permit the escape of fluid while the instrument is *in situ*. Irrigation and dilatation are performed simultaneously, and the ad-

vantage of the three prong construction is readily appreciated. Since most of the folds, lacunæ, and glands are situated on the upper surface of the urethra, the four prong dilator makes pressure directly against this surface, while the three prong instrument dilates it laterally and allows a full irrigating flow against the upper aspect, where it is most needed. The urethra is first flushed thoroughly with 150 c.c. of solution and the instrument is introduced as far as the cut off muscle. Slow, gradual dilatation is begun, and at the same time the canal is irrigated with a liberal amount of the solution. Care must be taken against overdilatation, and after the withdrawal of the instrument the entire urethra is again thoroughly flushed. Dilatations are made every second or third day, the patient continuing his hand injections until the urethra is well dilated, when all treatment is discontinued and the patient is kept under observation. I have never seen any complications from the use of this instrument, and have yet to find the first case where it has carried the disease posteriorly.

Should gonococci reappear after such a course of treatment, it is generally an indication that the deeper seated glands are involved and should be destroyed by electrolysis. After thoroughly cleansing the urethra, an endoscopic examination is made, and the infected glands are located by their wide, gaping mouths. The apparatus for electrolysis comprises an electrolytic needle, a milliampère meter, rheostat, and sponge electrode, so disposed that the patient holds the positive pole (sponge electrode) against the groin, while the negative pole (the needle) is passed through the endoscope into the open mouth of the gland. By making pressure on the small button in the handle of the needle, electrical contact is made, the rheostat is set for three to five milliamperes, and the application is maintained for from one to two minutes. Bubbles of hydrogen are seen to come from the gland opening. Four or five glands are thus electrolyzed at each treatment, after which the urethra is irrigated. It is important that the current for the light of the endoscope and that for the electrolytic needle be taken from different sources, so as not to cause a short circuit when the instruments are in place.

It is not within the scope of this paper to describe minutely the treatment of female patients, and I can only mention that our method follows the same general principles as outlined—first, definitely to locate the seat of infection and treat it locally by irrigations and applications. Here, too, mild solutions of protargol have served us well.

I wish to emphasize the importance of the systematic use of the microscope in treating this disease; first from a diagnostic standpoint. Surely no one can say positively of any given case of urethral discharge that the cause is gonorrheal unless gonococci are demonstrated. More than once has it been my pleasing experience to convince a patient who thought himself infected with gonorrhea, that his belief lacked foundation.

Since there can be no hard and fast rule as to the duration of an attack of gonorrhea, the physician is, and must be dependent upon the microscope for definite information as to the progress of his patient. No objection can be urged on the score of time needed, for a slide can be prepared and stained in a very few minutes. It is impossible to emphasize too strongly the need of employing all the scientific aids at our command in the fight against gonorrhea.

In conclusion, I wish to quote from Dr. George Luys, of Paris, who says in his *Traité de la blennorrhagie:* "Our therapy is nowadays so perfect that it is not permissible for a medical man to allow a case of gonorrheal urethritis to go on without curing it. Modern science has made such conquests that we can say without exaggeration that there is no inflammation of the urethra which cannot be cured completely by appropriate treatment. But it should not be forgotten that this result is obtained only by means of prolonged and painstaking observation and that urethroscopy alone enables us to diagnose the local lesions with accuracy, and to apply the sovereign remedy correctly. Without the control of his eye it is impossible for the medical man to select the best and most efficacious treatment."

30 East Forty-second Street.

HAY FEVER.

Its Relation to Seasons, Occupations, Sex, and Color,

By William Scheppegrell, A. M., M. D.,
New Orleans,

President, American Hay Fever Prevention Association; Ex-President, American Academy of Ophthalmology and Oto-Laryngology.

In our efforts to collect statistical information on hay fever, remarkable features were the paucity of available data and the many erroneous impressions in connection with the subject. Among the latter is the popular idea that the farmers, who are most exposed to weed pollens, are rarely subjects of hay fever. Among the criticisms of the relation of pollen to hay fever, this is frequently brought forward as a contradiction of the theory.

Another erroneous impression is that the colored population is rarely affected with hay fever. The first substantial contradiction of this was given when in company with D. D. Moore, editor of the *New Orleans Times-Picayune,* a popular lecture was given before the confederation of colored societies in New Orleans on civic improvement, in which the writer referred to the advantages of weed eradication from both a civic and sanitary standpoint. In discussing the lecture, the colored audience spoke of themselves or members of their families as suffering from hay fever in almost the same manner as a white audience. The quantitative ratio was afterward established by the United States Public Health Service.

Another popular fallacy, frequently referred to in works on hay fever, is that this disease is uncommon below the thirty-fifth parallel of latitude. South Carolina, Georgia, Florida, Alabama, Mississippi, Louisiana, half of Arkansas, and most of Texas are south of this parallel, but the ratio of hay fever cases to the population differs but little from those between the thirty-fifth and forty-fifth parallel.

Equally striking was the lack of information regarding the seasons of hay fever in the various States. With few exceptions, the State boards of health, to which the first queries on the subject were

addressed, replied that, as hay fever was not a reportable disease, the seasons could not be given. A large number of physicians in the various States were also unable to give this information. By persistent efforts, which were greatly facilitated by having representatives in almost all the States, the American Hay Fever Prevention Association has succeeded in obtaining definite information on the

FIG. 1.—Pollen of Johnson grass, Andropogon halapense. (45 microns magnified 500 diameters.) Important cause of summer hay fever. These pollens were photomicrographed at the biological laboratory of the American Hay Fever Prevention Association.

subject of the hay fever seasons. One of the difficulties presented is that the seasons are not always identical in all parts of the same State. This is sometimes due to a difference in the humidity of the soil causing marked change in the vegetation, as in the Gulf States; or a marked disparity in latitude owing to the size of the State, as in Texas and California; or a great variation in altitude, affecting the vegetation and its seasons of development.

In such cases, an average is made of the dates submitted, which is approximately correct for each State. The exact dates, however, are kept on file for special references. In California, for instance, reports were received from San Francisco, Los Angeles, Sacramento, and Berkeley, the seasons differing somewhat, but the average of May 5th to July 5th for the summer form of hay fever, and July 15th to September 10th for the autumnal form, are approximately correct for this State.

Other statistical information regarding hay fever, such as the relation of sex, occupations, and color, was obtained from the United States Public Health Service, which sent, through Epidemiologist Oscar Dowling, a list of questions to all the physicians of Louisiana. While these data refer more especially to the State of Louisiana, most of them are applicable to the United States generally.

THE SEASONS IN HAY FEVER.

The development of hay fever in any locality depends upon the atmospheric hay fever pollens increasing to a point which overcomes the resistance of the patient. This has been confirmed by the atmospheric pollen plates which have been exposed by our research department in various sections during the past hay fever season. It was ascertained that most of the spring and summer cases of hay fever are caused by the pollen of the grasses (Gramineæ, Fig. 1), although the pollen of other plants, such as the Yellow Dock (Rumex crispus), Amaranth (Amaranthus spinosus, Fig. 2), Goose foot (Chenopodium anthelminticum), etc., may cause the attack, or help to maintain it when set up by the grass pollens.

The cases of hay fever caused by the grasses are not only milder in character than those caused by the rag weeds, but are easier to prevent. The size of the pollen is relatively large (average forty microns in diameter), frequently twenty times larger than the common rag weed pollen (fifteen microns in diameter; Fig. 3). On this account, the grass pollens are carried a much shorter distance by the wind, and rarely remain long in the atmosphere. Municipal efforts, therefore, for its control have every prospect of success, as illustrated in New Orleans during the past hay fever season.[1]

The uniformity of the development of autumnal hay fever cases is practically always associated with atmospheric disturbances. In the vicinity of New Orleans, the rag weed usually begins to pollinate about August 1st, and on August 10th the pollen are in sufficient numbers in the air to appear on the exposed atmospheric pollen plates. This year, the number gradually increased until on August 20th it had reached seven per cent.,[2] with only a few reports of autumnal hay fever cases, these being from subjects living in close proximity to these weeds. On August 21st, the wind acquired a velocity of twenty-three miles an hour and the pollen count rose to eighty-seven per cent. The largest number of patients who had autumnal hay fever during the present season suffered their first attack within a few hours of this rise in the pollen count. The simultaneous development of hay fever in these cases

FIG. 2.—Pollen of spiny amaranth, Amaranthus spinosus. (20 microns magnified 500 diameters.) Minor cause of summer hay fever.

was therefore not psychical, but was due to the uniform distribution of the exciting cause.[3]

This rise of the pollen count also illustrates the buoyancy of the common rag weed pollen (Ambrosia elatior, Fig. 3). This weed does not grow within five miles of the residential section of New Orleans, being replaced by the giant rag weed (Ambrosia tri-

[1] Scheppegrell, *United States Public Health Reports*, July 21, 1916.
[2] For the sake of convenience, 100 pollen to the square cm. of exposed plate for twenty-four hours is considered 100 per cent. The amount, however, is sometimes much higher during the active season of pollination of the rag weeds.
[3] After the initial attack, the nasal mucosa becomes more sensitive and reacts to a smaller number of hay fever pollens.

fida, Fig. 4). During the prevalence of this wind, however, the number of common rag weed pollens exceeded those of the giant rag weed, whose greater size (twenty microns) reduces their potential area. Another important feature was that for a week after the high winds there was little difference in the number of common rag weed pollen per kilolitre near

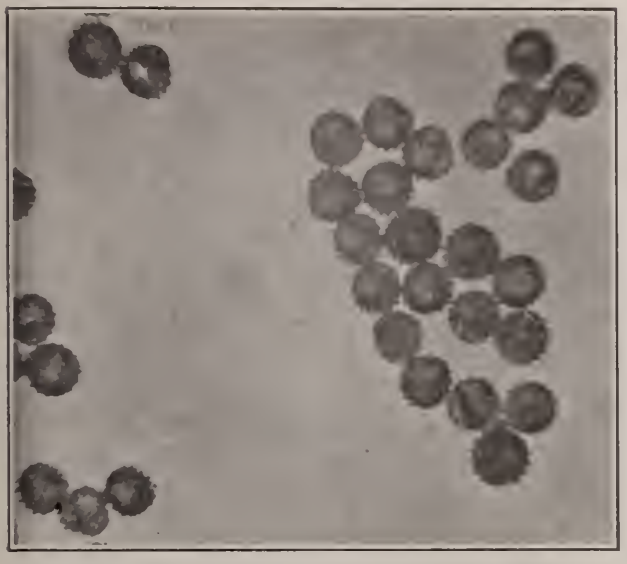

FIG. 3.—Pollen of common rag weed, Ambrosia elatior. (15 microns magnified 500 diameters), principal cause of autumn hay fever.

the ground (Biological Laboratory—ten feet) and an altitude of 100 feet (eighth floor of office building and tower of Loyola University).

The etiological relation of the rag weeds (Ambrosias) as the exciting cause of autumn hay fever was also clearly demonstrated. The development, increase, decrease, and final disappearance of hay fever bore a definite ratio to the atmospheric pollen count of the Ambrosias. On October 16th, when these pollens had practically disappeared (one to two per cent.), all reports showed that the hay fever season had passed.

The pollen of the Canadian golden rod (Solidago canadensis, Fig. 8), which is so popularly associated with hay fever, was never found on these atmospheric pollen plates. Its insignificance in hay fever was also proved by the fact that after the hay fever season in Louisiana had passed, the golden rod was still conspicuous for its florescence.[4]

The following table gives the approximate dates of the development of spring and summer, and of autumn hay fever. These have been obtained from the most reliable source available, most of them being an average of several answers received from each State.[5]

In any locality, the development of hay fever may be delayed by rains which prevent the spread of the pollen; or it may be advanced several days by weather conditions accelerating the growth and pollination of the hay fever weeds. An early frost may also shorten the autumn form.

HAY FEVER SEASONS IN THE UNITED STATES.

	SPRING AND SUMMER FORM.	AUTUMNAL FORM.
Alabama	April 15 to July 15	Aug. 18 to Oct. 10
Arkansas	June 10 to July 15	Aug. 16 to Sept. 17
Arizona	May 5 to June 5	July 15 to Oct. 1
California	May 5 to July 5	July 15 to Sept. 10
Colorado	May 10 to July 1	July 20 to Sept. 15
Connecticut	June 1 to July 15	Aug. 17 to Oct. 1
Delaware	May 5 to July 10	Aug. 13 to Sept. 20
Florida	May 1 to July 10	Aug. 18 to Oct. 10
Georgia	May 10 to July 5	Aug. 18 to Oct. 4
Idaho	May 5 to June 10	Aug. 1 to Sept. 16
Illinois	June 10 to July 20	Aug. 15 to Sept. 20
Indiana	June 5 to July 15	Aug. 17 to Sept. 25
Iowa	June 2 to July 16	Aug. 13 to Sept. 27
Kansas	May 16 to July 15	Aug. 16 to Sept. 28
Kentucky	June 1 to July 18	Aug. 15 to Oct. 1
Louisiana	May 5 to July 25	Aug. 20 to Oct. 16
Maine	June 5 to July 10	Aug. 17 to Sept. 24
Maryland	May 15 to July 10	Aug. 16 to Oct 5
Massachusetts	June 5 to July 18	Aug. 13 to Sept. 25
Michigan	June 8 to July 15	Aug. 15 to Sept. 25
Minnesota	June 5 to July 19	Aug. 14 to Sept. 26
Mississippi	May 10 to July 10	Aug. 18 to Oct. 15
Missouri	May 10 to July 26	Aug. 12 to Sept. 24
Montana	May 15 to July 15	Aug. 5 to Sept. 15
Nebraska	May 15 to July 15	Aug. 8 to Sept. 18
Nevada	May 1 to July 15	Aug. 12 to Sept. 15
New Jersey	June 10 to July 24	Aug. 17 to Sept. 28
New Hampshire	June 10 to July 16	Aug. 16 to Oct. 1
New Mexico	May 3 to July 5	July 12 to Sept. 28
New York	June 5 to July 19	Aug. 16 to Sept. 28
North Carolina	May 15 to June 29	Aug. 20 to Oct. 5
North Dakota	May 20 to July 15	Aug. 10 to Sept. 15
Ohio	May 28 to July 13	Aug. 13 to Sept. 15
Oklahoma	May 10 to June 24	July 25 to Oct. 1
Oregon	April 25 to May 29	July 1 to Sept. 1
Pennsylvania	June 3 to July 21	Aug. 16 to Sept. 27
Rhode Island	June 8 to July 22	Aug 15 to Sept. 26
South Carolina	May 10 to July 5	Aug. 18 to Oct. 10
South Dakota	May 13 to July 10	Aug. 8 to Sept. 22
Tennessee	June 5 to July 22	Aug. 15 to Oct. 5
Texas	May 15 to July 15	Aug. 18 to Oct. 15
Texas	June 22 to July 27	Aug. 5 to Sept. 15
Virginia	May 15 to June 29	Aug. 18 to Oct. 3
Vermont	June 10 to July 22	Aug. 14 to Sept. 24
Washington	June 12 to July 1	July 5 to Oct. 7 (Fall rains)
West Virginia	May 15 to June 29	Aug. 12 to Sept. 28
Wisconsin	June 7 to July 18	Aug. 17 to Sept. 28
Wyoming	May 1 to May 15	Aug. 5 to Sept. 15

PERCENTAGE OF HAY FEVER CASES.

Although sufficient data had been obtained from many sections to give an approximate idea of the proportion of hay fever cases to the population, no complete information was available until the United States Public Health Service sent out a list of ques-

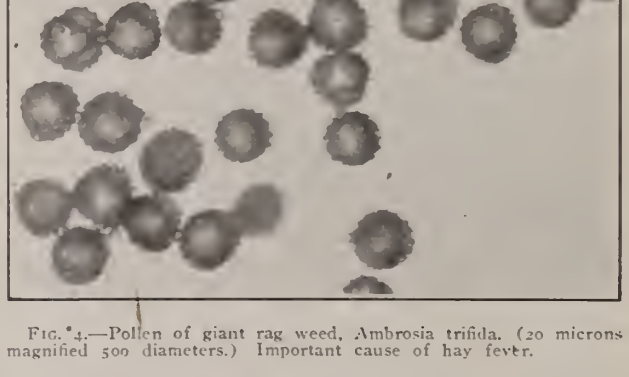

FIG. 4.—Pollen of giant rag weed, Ambrosia trifida. (20 microns magnified 500 diameters.) Important cause of hay fever.

tions to all the physicians of Louisiana. The result of this questionnaire, which was made at the request of the American Hay Fever Prevention Association, coincided closely with the estimated average proportion of hay fever cases, viz., one per cent. of the population. This percentage sometimes varies in dif-

[4] By means of the anemophilometer, an instrument devised in the biological laboratory of the American Hay Fever Prevention Association for testing the wind pollination of plants, it was shown that the amount of pollen distributed into the air by the golden rods compared with the rag weeds is practically inappreciable. Scheppegrell, *Scientific American*, October 7, 1916.

[5] Any further information on this subject submitted by practitioners in the various States, will be carefully considered for a future report on this subject.

ferent parts of the same State, owing to the change of the hay fever weeds which are influenced by climatic conditions and altitudes.

Great altitudes, however, are without the important influence that has often been ascribed to them In the section of the Allegheny range of mountains, hay fever is not only found, but is remarkably prevalent up to an altitude of 5,000 feet. Even at this high level the common rag weed is frequently found in the section east of Kansas. In the Rocky Moun-

FIG. 5.—Pollen of pine tree, Pinus palustris (42 microns magnified 500 diameters), distributed in enormous quantities, but negative in hay fever.

tain and Pacific States, in which the common rag weed is rare, the sage wormwood (Artemisia frigida) is found at altitudes as great as 6,000 feet and is a common cause of hay fever.

The answers of the questionnaire of the United States Public Health Service show that the proportion of hay fever cases in northern Louisiana was eight ninths of one per cent., and in southern Louisiana one per cent., or an average of 0.94 per cent. for the State. This is somewhat lower than the estimated proportion north of the thirty-fifth parallel, which is usually one per cent. or more.

The principal weeds that cause hay fever are largely parasites of agriculture.[6] This is especially the case with the common rag weed (Ambrosia elatior, Fig. 3), the seeds of which are disseminated in land recently brought under cultivation by means of the grains, hay, and cattle. On this account, hay fever is uncommon where there are extensive forests, but quickly develops where these are replaced by cultivated lands.

Although most of the trees are wind pollinated, only a few are responsible for hay fever. The pines (Pinus palustris et alii) generate enormous quantities of pollens (Fig. 5), which, however, are negative in hay fever. The oak, willow, ailanthus, and a few others are mildly positive, but are comparatively unimportant. One exception, however, is the cottonwood (Populus sargentii, Populus angustifolia being much less active), which gives a marked reaction in hay fever, and which is sufficiently common in some of the western States to cause a considerable number of hay fever cases.

In some of the western States the percentage of hay fever is found considerably below the general average, this being due, to a large extent, to the absence of cultivated land, of which most of the hay fever weeds are parasitic. As agriculture is developed in these sections, however, the number of hay fever weeds will rapidly increase unless special precautions are taken. In many of these places, hay fever, rare a few years ago, is becoming prevalent.

PROPORTION OF EARLY AND AUTUMNAL HAY FEVER.

Autumnal hay fever is the principal form in the United States, both on account of the greater severity of the disease and the larger number of cases. The answers to the questionnaire indicate that sixty-seven per cent. of the cases belong to the autumnal, twenty-eight per cent. to the spring and summer, and five per cent. to the combined form. While this is approximately correct for the United States generally, there are many sections in which autumnal hay fever forms eighty per cent. of all the cases. On the Pacific Coast, however, the earlier form of hay fever predominates, this being partly due to the absence of the common rag weed (Ambrosia elatior), whose ubiquity, aided by the remarkable buoyancy of its pollen, is responsible for eighty-five per cent. of the autumnal hay fever cases east of Kansas.

On the Gulf Coast, in what is known as the Zone of the Gulf Flora, in portions of Pennsylvania and Indiana, and in some sections of the Pacific States, the giant rag weed (Ambrosia trifida, Fig. 4) predominates. It gives a similar reaction to the common rag weed (Ambrosia elatior), but its greater size (twenty microns in diameter, or twice the volume and weight of the common rag weed) reduces

FIG. 6.—Pollen of wormwood, Artemisia heterophylla (22 microns magnified 500 diameters), one of the principal causes of autumn hay fever on the Pacific Coast.

its potential radius to one sixteenth of that of the common rag weed.

In the Rocky Mountain and Pacific States, autumnal hay fever is caused by the wormwoods (Artemisias, Fig. 6), marsh elders (Ivas), western rag weed (Ambrosia psilostachya), and gætnerias, which, however, are not as abundant as the common rag weeds (Ambrosia elatior) are east of Kansas. The larger size of their pollen also diminishes their buoyancy and correspondingly restricts their potential area.

Most of the causes of spring and summer hay fe-

[6] Many of the principal hay fever weeds are described in Hay Fever: Its Cause and Prevention, by William Scheppegrell, *Journal A. M. A.*, March 4, 1916.

ver are due to the pollen of the grasses (gramineæ), this being confirmed by the records of our atmospheric pollen plates during the past season.[7] While corn and rye belong to this family, the size of their pollens, especially of corn (Fig. 7, eighty microns), prevents them from causing hay fever except in close proximity to such crops.

A small proportion of spring and summer hay fever cases are caused by other pollens, such as of the dock (Rumex crispus and obtusifolius), goosefoot (Chenopodium anthelminticum and album), water hemp (Acnida tamarascina), etc., but these are usually more responsible for aggravating cases which have already been caused by the grass pollens.

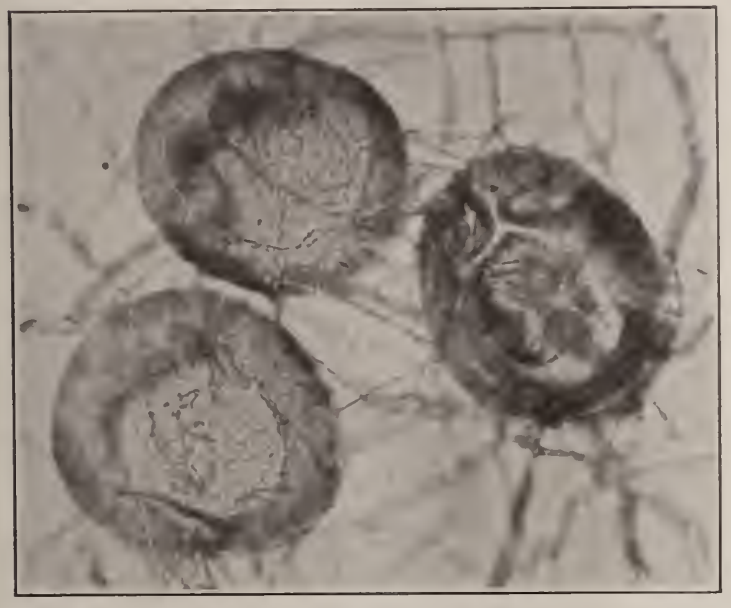

FIG. 7.—Pollen of corn (80 microns magnified 500 diameters). Its large size gives it a limited potential area.

AGE AT WHICH HAY FEVER DEVELOPS.

The age at which hay fever develops was found to be most common between twenty and forty years (sixty-two per cent.), the next most frequent age being between ten and twenty years (seventeen per cent.). Hay fever in children, however, is much more apt to be mistaken for "colds," as even in adults it is frequently not until the patient has had hay fever for several years that the periodicity of the attacks suggests the correct diagnosis. As the condition is better understood, it is probable that the age of the first development of the attack will be more correctly adjusted.

OCCUPATIONS OF HAY FEVER SUBJECTS.

The report on occupations is one of the most interesting results of this questionnaire. It is commonly supposed that persons in the country suffer little from hay fever, and the alleged fact that farmers are not affected is often used as an argument against the pollen theory. This investigation, however, demonstrates that the occupation which has the largest number of hay fever cases (thirty-eight per cent.) in Louisiana is that of the farmer. As they are most exposed to the pollen, this is only natural, and shows that the greater resistance due to their outdoor life is offset by the greater exposure.

Although professional men are supposed to be especially prone to hay fever, this was found not to be the case, as they represent only six per cent. of the cases. Next to the farmers, the greatest number of cases were in persons with indoor occupations (twenty-nine per cent.), those with outdoor occupations being nineteen per cent.

RELATIVE PROPORTION OF THE SEXES.

The proportion of males and females having hay fever is probably due not so much to difference of susceptibility as of exposure. The males have sixty-three per cent. of the hay fever cases against thirty-seven per cent. of the females, the difference being probably due to the men being more exposed to hay fever pollens by their occupations.

PROPORTION OF WHITE AND COLORED VICTIMS.

Many reports and books on hay fever refer to its rarity in the colored race. The answers, however, show that the proportion of white and colored are seventy-nine and twenty-one per cent. respectively. As the United States Census states that there were 713,874 colored and 941,086 white persons in Louisiana, this indicates that the colored are affected with hay fever about one third as often as the whites.

The data from which the information on the hay fever seasons was obtained were furnished by physicians in the various States of the Union, whose contributions were of great assistance. The cooperation of the United States Public Health Service is especially appreciated, as the answers to the questions on hay fever have furnished valuable information. While the analysis of the answers refers more particularly to Louisiana, the answers themselves will be found to be fairly applicable to the United States generally, and are therefore submitted as giving the first definite information published on this subject.

FIG. 8.—Pollen of Canadian golden rod, Soldago canadensis (15 microns magnified 500 diameters). Continues to bloom after the hay fever season has passed. Its pollens were not found on the atmospheric pollen plates.

844-846 AUDUBON BUILDING.

[7] The iodine-potassium iodide solution forms a convenient test for the grass pollens, as their starch contents quickly respond to the iodine. This solution is also a convenient stain, through its amylogenic reaction, for pollens in general, whose protein contents and reaction have been established by the biological tests.

SURGICAL IMMUNITY.*

Some Old and Frequently Neglected Factors.

By W. Wayne Babcock, M. D.,
Philadelphia,
Surgeon, Samaritan and Garretson Hospitals.

Therapeutics has long been typified by two schools, one militant and aggressive, the other passive and conservative. One rather disdains the normal forces, and seeks relief from external agencies, the other depends upon the natural defenses within the body which it tries to protect and develop. One is typified by the teachings of Benjamin Rush, and is represented by the drastic bleeding, purging, emesis, sweating, and refrigerating treatments that now have largely been discarded; the other by John Hilton, who, by rest and exemption from irritation, sought to conserve and render efficient the normal protective forces. While some of the more drastic types of treatment of the first form are no longer popular, the principle still exists in medicine, as is shown by the heroic, and at times indiscriminate internal use of antiseptics to supplant normal antibodies, of vaccines to lash the protective forces to increased endeavor, or serums to render less necessary the production of normal antitoxins. While we no longer see patients bled, and purged, and sweated until they collapse, we do from time to time observe patients with every evidence that their protective forces are struggling to the uttermost against a violent infection, now shocked by the intravascular injection of an antiseptic solution, again pale, perspiring, collapsed, from the throes of a violent chill after the intravascular injection of a vaccine, or burning and gasping from the secondary pyrexia; or in another case struggling against the superadded toxicity of an alien serum or protein, while blood tests, lumbar punctures, aspirations, polygraphic tracings, and other records performed at frequent intervals, prevent rest, increase pain and mental anxiety, and add to the exhausting effects of the disease. I do not wish to disparage or deny the usefulness of any of these important measures, but there are times when the patient must be considered first, and it seems to me a sad thing to see a desperately ill patient, especially one of prominence and wealth (for the poor ward patient more rarely receives an overplus of attention) surrounded by a group of highly trained—shall I say, ultrascientific?—consultants who vie with one another as to the number and type of examinations and immunity producing procedures they can suggest, or have carried out. There are times when rest, protection, and encouragement mean more to the patient than the most complete scientific examinations, or the employment of the latest methods for producing artificial immunity, and we should realize that we have not yet learned to interpret the reactions obtained in healthy young animals in the light of the tissue reactions of the desperately ill human subject.

It is not my desire to speak as much of aggressive or militant measures in medicine, of which I see little, as in surgery, of which I see more. It is not long since that we had what has been well termed the "carnivorous" period in surgery, in which the operator, proud of his boldness and daring, fell upon the patient, and with much tearing, rending, and crushing, triumphantly tore away the diseased part. For minor conditions the surgeon was also aggressive; scraping, scrubbing, disinfecting, gouging, squeezing, milking, punching, packing; unmindful of the fact that traumatized tissues suffer more than do the contained bacteria. Fortunately, in surgery, the present tendency is to treat damaged tissue cells with more compassion; precision and gentleness distinguish the modern operator, rather than quickness and boldness. And yet the militant spirit has not entirely disappeared, and we have not fully learned the great principle that *it is not what we put into the tissues, but what we get out of them that determines recovery from disease.*

For the successful treatment of many surgical conditions the production of an artificial immunity is much less important than the maintenance of the normal bodily resistance. Too frequently we forget that vaccines and serums can never replace such timeworn aids to immunity as rest, support, noninterference, protection, and other important measures that have been reiterated and forgotten many times. It has been well said that surgery should be retaught every seven years, so that the useful things of the past are not forgotten and thrust aside by the innovations of the present. It is my intention briefly to review a number of conditions in which attempts to produce artificial immunity are of secondary importance in the treatment of the affection. As surgeons no longer believe that disease is an evil to be scourged from the body by fire and other drastic measures, inflamed tissues are handled with greater gentleness, not because the handling is painful, but because we realize that traumatism may destroy the local immunity, or may diffuse infection beyond imperfectly erected tissue barriers. It has long been recognized that absolute, general, and local rest, frequently determines whether a contused wound leads to disorganizing infection, or a simple aseptic wound healing. A crushed hand treated by aseptization, and a careful dressing, but put back at once to work, is frequently followed by a disorganizing phlegmon that spreads up the arm. The same injury treated with a simple wet dressing, support, elevation, and complete local and general rest, may heal without inflammatory reaction. Against the handicap imposed by the first plan of treatment, no vaccine or other measure for the production of artificial immunity will avail. Again, many of us have seen a crushed and lacerated hand treated by painstaking aseptization, and the most accurate suture of the divided deep and superficial tissue, swell, become necrotic and disorganized from tension, infection, and secondary inflammatory processes. The same injury treated without suture of the divided tissues, especially the overlying skin, but by the free division of any skin that may cause constricting tension when the secondary swelling occurs, may heal with no sign of infection. No method of artificial immunity has been devised that will take the place of absence of local tension, or of local or general rest in the treatment of certain wounds.

Local traumatism has many examples as to its influence in decreasing tissue immunity. In the second stage of appendicitis a free incision with wide

*Read at the seventeenth annual meeting of the American Therapeutic Society, Detroit, Mich., June 10, 1916.

separation of adhesions, and especially the thorough scouring or mechanical or chemical cleansing of the peritoneum, opens lymph spaces, overcomes the local protective process, and is often followed by an overwhelming and fatal toxemia or bacteriemia.

In perforation in typhoid fever the mortality has been shown to have a distinct ratio to the extent of the intraabdominal manipulation, being greatest with evisceration and thorough irrigating and cleansing of the cavity, less when cleansing is accomplished only by careful sponging, and least when only the simple occlusion of the opening with drainage is carried out.

In curettage for septic infections of the endometrium, especially after abortion, the use of the sharp curette sows the bacteria into the deeper tissues and permits widespread invasion, and probably has been responsible for many tubal and pelvic infections.

In acute local infections how often puncture or ineffective incision increases the inflammatory process! The pustule that is punctured or squeezed becomes a furuncle, the furuncle that is traumatically irritated becomes a carbuncle, the carbuncle that is massaged, punctured, and squeezed, may terminate in a fatal bacteriemia.

The traumatism of a local anesthetic, or the general toxemia of inhalation anesthesia, may also seriously reduce a patient's immunity. An infection involving the root of the second or third molar treated by the usual simple dental methods, may resolve without serious symptoms. Extraction under nitrous oxide may be followed by a sharp attack of osteomyelitis of the jaw. If at the height of this osteomyelitis the patient is deeply etherized, the tissues are freely incised, the maxilla is thoroughly scraped, curetted, or gouged; the patient may be lucky if he escapes with his life. At the acme of an acute surgical infection operative intervention must be carried out with great care, and is often a source of great danger. An acute streptococcus or staphylococcus lymphadenitis of the groin, neck, or other part of the body, in the acute stage when the fever is high, the pulse rapid, the tissues' defenses as yet unerected, is often best let alone; if incised at all at this stage, it should be opened with the least possible local traumatism, and in the simplest manner. I have seen several deaths follow the careful enucleation of glands in such an acute inflammatory stage. At a little later stage, drainage, or enucleation may safely be carried out. Likewise in an acute infectious phlebitis of the leg, I have seen massage followed by sudden pulmonary embolism and death, and in every case that has come to my knowledge in which an attempt has been made to remove the vein, or the clot from the vein, in such an acute septic condition, the patient has died of a general septicemia. On the other hand, for a suppurative inflammation within a vein, a simple sharp incision after the acute stage has subsided, carried out with the least possible handling or local traumatism, is a relatively safe procedure.

In septic thrombosis of the cranial sinuses, recovery following the removal of clots with curettage of the sinus, or the irrigation of the sinus, in my opinion usually occurs in spite of the treatment rather than because of it. In these infections the operation should be limited to a simple incision with drainage, and no attempt should be made to break down the clot, or to open through the clot into the normal blood stream.

The bacterial element. Much depends upon the causative bacteria. In an acute salpingitis due to the staphylococcus or streptococcus, abdominal section is a serious procedure, and many unnecessary deaths have followed such an intervention despite free drainage and an attempt to isolate the septic focus. On the other hand, an acute gonorrheal salpingitis may be treated by abdominal section almost with impunity. The pus that enters the peritoneal cavity produces little irritation, and what escapes into the skin incision does not infect it. The skin and deeper tissues may therefore be closed without drainage exactly as if no pus was present, and no attempt at disinfection or protection of the tissues from the bacteria and pus cells is required. We have usually found such wounds to heal with little or no signs of irritation; the reason of course is the fact that the gonoccocus shows its chief influence upon the mucous membranes and the smaller serous sacs, rarely produces a serious peritonitis, and is without influence upon the skin, fat, or fascia. Likewise in acute tuberculous infections, especially of the peritoneum or of the lymph nodes, operations carried out during the acute stage seem to involve little danger of diffusing the infection. Upon the other hand, there seems to be some danger from trauma in the operative treatment of an old tuberculous joint cavity, especially when later fixation and rest cannot be carried out. In suppurative conditions due to Bacillus typhosus, early surgical intervention also seems to involve little additional risk.

In acute metastatic arthritis the importance of rest and support cannot be too greatly emphasized. In the acute stage rest is to be obtained by extension and aspiration, so that the joint surfaces are held apart, with proper support by bandages and appliances to prevent movement. In these infections neglect of these simple measures is often responsible for a disorganizing arthritis that leaves the patient crippled, possibly for life. For certain chronically stiff joints due to traumatism, however, where infection is not a factor, rough handling, breaking up of adhesions, so called "bone setting" manipulations, often promptly restore function to the damaged joint, so that judgment is required in the selection of cases that require support and rest, and in cases that need violent disruption of limiting adhesions.

Anthrax is a good example of a disease in which complete rest is a great factor in aiding the recovery of the patient. In guineapigs and some other lower animals anthrax produces a rapidly fatal bacteriemia. In the human subject, the tendency is for this organism to produce a localized carbuncle, more rarely a bacteriemia. The usual treatment for such anthrax carbuncles has been most drastic. It has usually been advised to burn out or excise the infected area, and to apply strong antiseptic solutions. Curettage has often been used, or injections made of weak solutions of carbolic acid around the carbuncle. It is difficult to

believe that even the most drastic of these measures suffices to destroy all the bacteria in the area, and the result of such brutal treatment must mean the breaking down of many tissue barriers, and a tendency to increase the danger of blood invasion. Von Bergmann has shown how well anthrax pustules heal when treated simply by complete rest and local protection, the local agents employed being of the blandest character possible, while no incision or mechanical separation of the secondary sloughs is undertaken.

Heat and cold are agents often improperly employed. After the very early stage of inflammation, cold should be discontinued, as it retards the normal protective forces and may cause vesiculation or necrosis of the skin. From the prolonged application of ice bags in appendicitis, the patient may come to operation with the abdominal wall partially necrotic.

In normal healing, especially in the old and very young, the diabetic, or debilitated patient, repair is often retarded by the use of such toxic applications as iodoform, bismuth, or carbolic solution. Dr. Robert T. Morris has pointed out the value of protectives or epithelial conductors which give local rest and protection in epithelialization.

Finally, while we would not disparage the use of measures to produce an artificial immunity, we urge that the surgeon have vision enough not to let them interfere with more important, although perhaps old fashioned measures that conserve the normal immunity of the patient.

2033 Walnut Street.

THE PSYCHOPATHOLOGY OF NOISE.*

By A. A. Brill, Ph. B., M. D.,
New York.

Those who are acquainted with the nature and mechanism of the psychoneuroses, particularly hysteria, know that the psychoneurotic symptoms are polymorphous in distribution, and that there is no part of the somatic or psychic spheres that does not on occasion assume the role of a hysterogenous zone or symptom. No function is spared; and no matter how great our experience may be, there are always surprises in store for us. From my own experience I can state that every case evinces something that is new and strange, which I dare say could never be imagined by the most experienced and fertile imagination. To cite only a few examples that have recently come to my notice: We usually expect nervous women to be more nervous during the menstrual period, but I was surprised to hear from an hysteric who consulted me for chronic exhaustion, that the only time she felt strong was during this period. A man cannot move his bowels in the morning because it causes pain for the rest of the day, but when this function is performed in the evening everything goes well, even if he remains awake the whole night. A man suffers from an attack of migraine which is always aggravated during his wife's menstruation. A woman becomes nauseated when she is disturbed by certain noises. Such examples are very common, and, although at first sight they give the impression of strangeness and lawlessness, we regularly find on deeper investigation that they follow a certain regularity in reaction.

Of late years I have endeavored to classify and study the psychoneurotic disturbances of the different physical and psychical functions with a view of throwing some light on normal and abnormal reactions of the functions concerned, and I shall discuss here some of the results.

Aphonia as an hysterical symptom is generally found in the textbooks under the caption of Disturbances of Motility and belongs to the somatic disturbances of hysteria, but when we analyze an hysterical aphonia, we soon find that the manifest symptom is only a fragmentary expression of a general psychic disturbance in the sphere of speech or, more precisely expressed, in the sphere of sound. Thus the first case of hysterical aphonia which came under my notice not only evinced attacks of aphonia lasting from days to months, but the intervals between the attacks were characterized by other strange disturbances in the spheres of sound expression. Thus the patient had attacks during which she spoke in an embellished manner; at other times she showed distinct flighty speech varied by attacks of crying and screaming. I remember that at first her hysterical speech manifestations recalled the manic depressive symptom complex, although there was no doubt that we dealt with a clear case of hysteria. Since then I have seen a number of cases showing in a very pronounced manner symptoms referable to the spheres of sound expression, and some of the results are very interesting. To be sure we are well aware that disturbances of sound expressions have always been known to participate in the symptom complex of the psychoneuroses. Even in our college days, the professor could not possibly speak of hysteria without mentioning crying spells and laughing spells, and he never failed to tell us that patients often laugh when they should cry, and cry when they should laugh. But as far as I could discover none of our old professors ever made the effort to explain these paradoxical manifestations, nor could the patient explain them. I have on record eleven patients who asked for treatment mainly because they suffered from obsessive spells of screaming. The patients themselves were as mystified by their attacks as their relatives and friends, and conceived their affliction as disagreeably as the persons surrounding them. To illustrate, I am selecting one of the simplest cases:

Case. Mrs. S., a woman of forty-six years, complained of spells of obsessive screaming with which she had been afflicted for years. She stated that she would suddenly begin to scream without reason and continue for about two to three minutes or longer until one or all members of her household came upon the scene. She would then stop and feel much ashamed of her action; sometimes the screaming spell was followed by a long crying spell. Examination showed that we dealt with a case of anxiety hysteria, which showed most of the other symptoms of that malady. Thus one of the very aggravating symptoms was a hyperesthesia to sound.[1] She could not fall asleep because the slightest street noise was most disagreeable and annoying, yet the monotonous ticking of a watch always calmed her to sleep. Here, we see, we were con-

*Read before the Vidonian Club, March 24, 1916.

[1]Cf. Freud: *Papers on Hysteria*, p. 134; Brill: *Psychanalysis, Its Theories and Application*, p. 82.

fronted with a contradiction. One sound was extremely annoying to the patient, but another sound acted soothingly. What was still more peculiar was that the ticking of a clock was more offensive to her. It was almost impossible for her to live in any summer hotel or travel because no matter how secluded the rooms were, she was sure to hear the clocks in the office and in the adjoining rooms. That the ticking of the watch should act as a hypnotic and the ticking of the clock as an excitant, or that the same stimulus should produce different results is not very strange; pharmacology offers many similar examples. As we know, there is hardly a hypnotic or narcotic that does not act in a similar manner. Thus alcohol, morphine, and many other drugs act differently on different persons, and a mere change of dose will produce in the same person stimulation instead of calm sleep. It may therefore be said that the same sensory perceptions and feelings, no matter how produced, may act in two ways, stimulating and exciting, or retarding and paralyzing. Now without going into a long discussion on the nature and mechanisms of hysteria as conceived by Freud, with which most readers are acquainted, I will briefly give my finding of this case. Mrs. S. was unhappily married. From what I heard of her husband, I was convinced that he was a paranoid character whose commitment to an asylum was only a question of time. He literally tortured her, and their two children, he denied them the bare necessities of life despite his great wealth, he was extremely jealous of his son whom he had often beaten brutally at home and in public places, he drank to excess, he was filthy in his habits, and his sexual life was abnormal. There were a great many other factors in the case which need only be superficially enumerated here to show the true situation. She was a girl of the middle class, and when she met her husband she was engaged to be married to a man of her own station. She broke her engagement and married the rich man. Years later, when she was very unhappy with her husband, she went through a rather tragic intrigue with her former lover. In fine, we could easily demonstrate all the etiological factors of an anxiety hysteria, and analysis showed that the screaming spells always appeared at the height of a revenge fantasy against her husband or lover. At times she began to scream when she reflected over her hopeless lot and fancied herself committing suicide. In the language of psychanalysis, the screaming was merely a flight from painful thoughts, the loud noise drowned as it were the inner painful and disagreeable voices.[2] Similar mechanisms were found in all my other cases of obsessive screaming; the noise was a flight from reality, like the familiar fainting spells which always appear at the proper moment, and like the artificially produced flights through alcohol (dipsomania) and drugs (morphinism), the aphonia also represented a flight. It usually appeared when she was about to see her husband, or when she was about to have an interview with her lawyer; to be sure the symptom was more complex in its determination, showing the mechanism of "displacement from above to below."[3]

It is to be noted that all the other patients were suffering from anxiety hysteria; only three showed besides some conversion symptoms.[4] It is a fact that the symptoms of anxiety hysteria evince more primitiveness in their manifestations than those of pure hysteria.[5] This is particularly true of those manifesting themselves in screaming spells which recall the defense mechanism of early childhood. Children one and two years old always react to annoyances with screaming, a reaction which gradually disappears with the advance in age, but which always remains as the characteristic expressionless scream in those who are mentally stunted, especially idiots.

The eleven cases of screaming spells studied by me did not belong to Doctor Hoch's shut in personalities; they did not represent the quiet thinking kind of persons who suffer in silence, and then react with a complicated conversion hysteria or with a philosophical præcox system; on the contrary, they were of the talkative sort whose reactions, even in daily life, express themselves in laughing, crying, and shouting. Their neurotic and psychotic reactions were distinctly of the infantile type. For it is well known that the great majority of hysterias among children belong to the group of anxiety hysteria; we rarely see a conversion hysteria among children. And when we study primitive people we find that their neurotic reactions are plainly of the infantile type. In my paper on *Piblokto* I showed that the hysterical attacks as evinced by the Eskimos were all of the same nature. Instead of a complicated hysterical attack they manifested an emotional outburst of the most primitive type. Professor MacMillan, who was with Peary, described the attacks as follows: "A woman will be heard softly singing and accompanying herself by striking the fist of one hand with the palm of the second making three sounds, one long followed by two short ones. The rhythm and motion continue to increase for some time, during which she usually tears off her clothing and ends in a fit of crying or screaming in which the woman may imitate the cry of some familiar animal."[6] It is therefore safe to say that those neurotic and psychotic symptoms which manifest themselves through disturbance of sound expression, especially noise, belong to the most primitive and infantile periods. It may also be assumed that most of the neurotic disturbances of sound expression appearing in the form of noise or flighty talk in maniacs, serve as paralyzers of conscious reflection in order to drown disagreeable and painful feelings. It often happens that so long as the patient is maniacal and has flights of ideas, he is also happy, and the moment his flights stop and he becomes retarded or mute, he is also depressed.

As neurotic and psychotic persons show only exaggeration of the normal, we may ask whether normal persons make use of sound or noise in a manner similar to the cases described. According to Lessing, this is actually the case. He says: "The tendency of the person to make a noise and act noisily, one of the deepest and most fundamental tendencies of the human psyche, having its origin in the impulse to live, to act, and to be powerful, may at the same time be the expression of a need for numbing consciousness, or quite the opposite, it may be the expression of a need for excitement and stimulation.[7] That is, noise and the tendency of people to be noisy where noise is unnecessary is most intimately connected with the wish for rest and calm. Just as alcohol is used to deaden worry and produce instead a sense of euphoria, so music and its spurious part, noise, act as strong human narcotics; they control the painful tension of conscious thinking and paralyze it when it becomes dangerous. Lessing also maintains that the amount of noise evinced by a person, a people, or a state of culture, is in the first place to be conceived as the standard of its psychic and intellectual state of development. It shows whether the impulsive emotional side, or the rational psychic interest of the subject predom-

inates. Thus it is known that the southern races live and manifest themselves more loudly because they are backward in the rational control of the impulses, and in the discipline of life characteristic of the more intellectually developed northern races. All human beings, no matter of what race, show a tendency to fly from consciousness, and what music does for the majority of intellectual persons, noise does for the masses. It takes us away from conscious reflection, and from the knowledge of our own empty existence. That probably accounts for the enormous amount of money spent on music. Mr. John C. Freund, the editor of one of our leading musical journals, stated at the Saratoga convention of music teachers, held in June, 1913, that exclusive of musical comedies, the amount spent annually in the United States for music in all its forms was $593,000,000. This only shows how we crave narcotics, or how much need we have for forgetting reality.

Still when we enter into the lives of some persons we find that not all behave alike to sound. Thus I know a musical genius at present very much engrossed with futuristic music, who suffers from an extreme degree of auditory hyperesthesia. In fact he first consulted me for insomnia, which he maintained was caused by street noises in the city, and by whippoorwills and crickets in the country. Here we have a person who is kept awake by the slightest sounds, but speaks of Schönberg and Strawinsky as the greatest composers that ever lived. I am sure that among patients who come to doctors complaining of insomnia because of noise, we often find some who are themselves very noisy. Indeed some of the greatest apostles of the antinoise movements belong to this type. They were either noisy or show the need for noise. Thus John Stewart Mills, who was fanatical on calm and rest, and an enemy of all noise, hired a boy to beat a drum next to the room in which he worked in order to stimulate his thoughts. It is also known that Hegel finished his principal work on the eve of the battle of Jena amidst the thunder of cannon, which, he averred, stimulated his thoughts. In these cases noise, which usually interferes with conscious thinking, produced the opposite effect, it stimulated thinking. This again can be compared to a remarkable neurological fact. A drug, which in normal states would be a stimulant and keep a person from sleeping, will produce sleep in states of exhaustion when the patient is so tired and restless that sleep is impossible. Sleep according to its nature is a diminution of conscious ideation, and hence cannot take place when the stream of ideas is already so exhausted and diminished that concentration on a single idea is impossible. The mechanism of dreams, as we know, is based on the fact that day remnants capable of wish formation are taken up and made into dreams in order to deflect the interest from consciousness and so enable the subject to fall asleep. So also in some abnormal cases, especially in subjects of the acoustic motor type, noise serves to release that amount of affective vividness which helps to grasp and adhere to thoughts having no special feeling tone. According to Lessing, these mechanisms are demonstrated in Charles Dickens and Thomas Carlyle. Next to Schopenhauer, the former was probably the first great writer who took up the fight against noise. In 1864, he edited a pamphlet containing antinoise arguments contributed by some of the greatest persons of his time, and in every way showed himself as an implacable foe of noise. Yet despite his oversensitiveness to noise, he evinced a general need for it. When we read his letters and diaries, we find that he felt himself so much a Cockney that he could not stay away for more than a few weeks from the noisy streets of London. He repeatedly complained that the lack of streets and the lonesomeness of the country caused him headache, anxiety, and dizziness. He evidently possessed so much animal spirit that he needed a constant nervous stimulant where a more delicate person would need a sedative. He was constantly annoyed and driven from place to place by negro minstrels and German bands, yet he could not dispense with the noise of the great city which he seemed to require either as a stimulant or narcotic.

Carlyle presents a similar case. It is notorious that noise played a most important part in his life. The diary of his wife, Jane Wels Carlyle, is filled with entries about the tortures she went through on account of her husband's annoyance and rage at noise. Although his studio was soundproof and was situated in one of the most secluded spots in Chelsea, he continually repeated that a person can neither think nor exist in such noisy surroundings. On the other hand, it is well known that he himself was one of the loudest of all rhetoricians, that he was a burden to his neighbors. Darwin, speaking of a visit to Herbert Spencer, where he met Carlyle, says of the latter: "That unbearable man sat for three hours and talked to me continuously about the 'sacred force of silence.'" Carlyle was so full of emotion that he simply could not bear any stimulus emanating from others. Carlyle's type is very common in psychiatric practice; I have seen many. I had under treatment one of the most active men in this city; to use his own words, he was constantly on the go. It is no exaggeration to say that he was occupied every minute of the day. He was known to be a good pedestrian, and when free from business duties, he walked miles daily either in the city or country. Yet one of his chief complaints when he came to me was that he hated to see objects like moving trains, or the moving electric signs on the Great White Way. He maintained that they drove him to distraction. He also hated persons who resembled him in activity. This man suffered from an anxiety hysteria, and judging by him and others, I have no doubt that most of those who are suffering from auditory hyperesthesia to the extent of making a problem of noise, are confirmed psychoneurotics. The symptoms complained of by Dickens, headaches, anxiety, and dizziness, belong to the most prominent symptoms of the anxiety neurosis, and any one who reads the life of Carlyle, especially as depicted by his wife, will entertain no doubt as to his anxiety hysteria on the usual etiological basis, sex. That music or its spurious part, noise, should play a part in the love life of a person, is not at all strange when we consider the part played by sound in every person's life. The first forms of expres-

sion in the human being are produced by primitive sounds which to the outsider are nothing but disagreeable noise, and music is merely a rhythmic combination of primitive sounds which develop with age. In other words, the older and more civilized a person, the quieter is the rhythm. It is well known that music which deals with the emotions of love is calm and soothing, while martial music is loud and noisy.

As all culture is psychologically a rationalization or control of affects, and a localization of human impulses, the older and more civilized a nation, the more controlled and refined are its impulses. Homer characterizes the mental superiority of the Greeks over the Trojans by making the Greeks march into battle without noise and without war cries. The Japanese of today is ashamed to express loudly his sorrows or joys, whereas the southern nations are very noisy in all their emotional manifestations. Our own "strong personalities" are usually the loudest noise makers. But even in our own environment, where the accomplished conversationalist is highly favored in society, it is considered a great compliment to be able to pass time with a person without having to talk much. As one of my patients put it: "It is such a comfort to spend a few hours with Mrs. X; we understand each other so well that we don't have to talk at all." The language of lovers is usually subdued and quiet, though wooing, which presupposes aggression and combat, is usually loud and noisy in the male.

The question may be asked, why such music as Wagner's which depicts the most subtle emotions is rather loud and noisy, and why the last word in modern music is so cacophonous and noisy that some of our greatest musicians refer to it as excruciating.

The real Wagnerian music began with the *Flying Dutchman,* when Wagner, having been disappointed with love and with life, in fine with reality, sought refuge in his early infantile fancies.[8] The love impulse which could no longer be gratified in marriage, found an outlet in the fantasies of his boyhood years. Wagner identified himself with the legendary flying Dutchman, and all the heroes of his later operas were modified reproductions of the Dutchman, or concrete visualizations or reincarnations of his fantasies from childhood. Wagner saw himself in the flying Dutchman, and later the same figure appears in his other operas, thus Tannhäuser, Wotan, Tristan, Amfortas, all of them showed the same traits, the same struggles; they all strove for the love of a woman, they were all tired of life, and longed for death. The heroines, too, were only symbolizations of the same figure, namely, his own mother. Senta, Elizabeth, Elsa, Eva, all represent the same type. As Wagner's music had its origin in his stormy childhood and dealt with primitive infantile feelings, we can understand its seeming loudness. There is a marked difference, however, between Wagner's music and the modern futurist music, a difference which we can also find when we compare the other forms of art with their most recent modes of expressions. Wagner's music, as well as most music of his predecessors, was an expression of *object love.* Any one studying Wagner's intimate life and his works can clearly see it. He himself as well as his heroes constantly sought salvation through a woman. The same was true of most of the other artists. Their productions were as a rule the expression of heterosexuality or homosexuality, but they represented object love. On the other hand, most of the futurist music, like the futurist art, is an expression of autoerotism or narcism.[9] Here no effort is made to put oneself *en rapport* with anybody, the artist strives only to gratify himself and cares little for the audience. That is why the futurist music offers no harmony or rhythm in the usual sense; for harmony and rhythm are expressions of object love. One of the great leaders in this modern art in this country expressed this feeling when speaking of his own productions, he said: "As to its content, it should satisfy my need of creating a record of an experience."[10] Such productions may possess great artistic value, but they can hardly be called "artistic expressions"; they are expressions of an artist. They satisfy his feelings and have no meaning to any one else. We behave toward those artistic expressions as toward some one else's dreams; we are interested only when we know their meaning. That is why over fifty intelligent adults could not tell what Mr. Walkowitze's *New York* represented. That is why the futurist music is so cacophonous and noisy to most people. Such productions are nothing but adults' attempts at rationalization of primitive infantile sounds without any attempt at rhythm which, as its name signifies, means to put oneself *en rapport* with others. Any one listening to Wagner's *Passions Musik und Liebestodt,* or the storm scene in the *Flying Dutchman,* can easily divine what Wagner was trying to represent, whereas it is hardly possible to tell the meaning of anything produced by Strawinsky, Ravel, or the other futurists. We might say it is the artist's attempt to give expression to noise, and to judge by some of the enthusiasts of this music, I feel that they are more than first cousins to the antinoise protagonists.

Localization of Variola.—Fritz Willner (*Medizinische Klinik,* October 1, 1916) asserts that the early diagnosis of variola is often a matter of considerable difficulty, especially in persons who have gained some degree of protection from previous vaccination. Willner has observed the appearance of the characteristic eruption and its rapid development on the inner surface of the prepuce. The eruption develops in this location before it is present on any other portion of the body, and this may be of great assistance in the early diagnosis of doubtful cases. On the third day small, bright red points appear on the prepuce. They develop into vesicles on the next day, with clear contents; pustulation appears on the fifth day, and these break on the day following. The smegma is then found to contain Guarnieri's bodies. Healing is complete by the end of the second week.

PROFOUND SECONDARY ANEMIA DUE TO ULCERATED INTERNAL HEMORRHOIDS.*

A Report of Three Cases,

By J. F. Saphir, M. D.,
New York,

Assistant Surgeon, Rectal Department, O. P. D., Gouverneur Hospital; Visiting Surgeon, Diseases of the Rectum and Anus, People's Hospital; Etc.

My object in presenting the following cases of profound secondary anemia is to bring before the profession, as forcibly as I know how, the effect of neglect of patients who pass blood with the stools; the great quantity of blood that can be lost on account of ulcerated internal hemorrhoids, almost completely exsanguinating some patients, while driving others into invalidism, to succumb to the extreme loss of blood or to some other disease which they have acquired.

Case I. Mr. M. G., aged twenty-four years, operator, was referred to me by Dr. Dexter D. Ashley, who had been treating him for the past three years for some orthopedic condition caused by a fall. He received ten tuberculin injections at the Vanderbilt Clinic. At the ninth injection, he lost one pound and a half and then discontinued treatment. For the past seven or eight years he noticed blood with his stools; the past two years he passed blood with every stool; and on straining at stool, whether with a constipated or diarrheal movement, he noticed protrusions with blood and mucus, from four to six stools a day. April 26, 1916, proctoscopic examination revealed proctitis with ulceration and ulcerated internal hemorrhoids. He was put under the irrigation treatment for his proctitis, which was relieved. He then had but one movement a day, and there was no further discharge of mucus, but he still passed blood with his stool. I then lost track of him until June 9th, when Doctor Ashley sent him into the People's Hospital for operation. The history he then gave was that he lost blood with every stool, felt very weak, was unable to work, had lost fourteen pounds in weight, weighing only 122 pounds, while his maximum weight was 136; and in the past three months lost eight pounds. He complained of general weakness, shortness of breath, and cardiac palpitation, especially on going up stairs. For the past three weeks he had been nauseated, especially in the morning, and he vomited occasionally. He also complained of dimness of vision and dizziness. On examination, I found a young man profoundly anemic, with a waxy, deathlike look, face white to a ghastly yellow, mucous membranes blanched; he breathed with difficulty, and complained of palpitation. The patient was lackadaisical, stupid, and unconcerned as to his surroundings. His general appearance was that of one suffering with malignant disease. I placed him under tonic treatment, consisting of dilute hydrochloric acid minims xv, three times daily, Fowler's solution, and iron, quinine, and strychnine, and ordered immediate transfusion of blood, because he was in too weak and exsanguinated a condition to be operated upon under either local or general anesthesia. His lungs were negative, and his heart presented a systolic murmur over the base and apex and slightly over the axillary space. Through the kindness of Dr. G. I. Miller, he received, on June 15th, a blood transfusion from a healthy male adult, aged twenty-five years, of 1,100 c. c. He began to show immediate improvement, his color was getting better day by day, but his bleeding per rectum persisted; he continued the tonics, but was still in too weakened a condition for operation. June 29th, I injected a ten per cent. solution of quinine and urea hydrochloride into the hemorrhoids, to check the bleeding. This caused a production of fibrin, which by mechanical pressure about the damaged vessels checked bleeding. Hemorrhage stopped after the first injection, but I also noticed that the hemorrhoids began to shrink, so I followed this up with injections, July 3rd and August 25th, with the result that the hemorrhoids shrank and were absorbed, his bleeding ceased, and no further operative measures were indicated.

Examination of blood showed the following stages of improvement: June 9th, on admission, red cells 2,800,000, hemoglobin thirty per cent; June 17th, two days after transfusion, red cells 3,950,000, hemoglobin sixty per cent; September 5th, red cells 5,250,000, hemoglobin seventy-five per cent.; October 5th, red cells 5,800,000, hemoglobin eighty-five per cent.

He now has good color, his mucous membranes are normal, he attends to his work, and has gained eleven pounds in three weeks, his last weight being over 140 pounds on October 5th, a gain of four pounds over his previous maximum.

Doctor Ashley, in speaking of the case a few weeks ago, told me that on the day previous to his admission to the People's Hospital, he asked a certain hospital to admit this patient, but the admitting physician refused, because he considered him moribund; and the patient tells me that this same admitting physician told the patient's relatives that he could not live twenty-four hours.

Case II. Mr. K. C., aged sixty-two years, merchant, referred to me by Dr. G. G. Wolf, September 9, 1916, gave a history of operation for hemorrhoids two years ago to relieve protrusions and profuse bleeding at every act of defecation. He felt well for a year. During the past year he again noticed bleeding with every movement, which got worse daily and more blood was passed with each successive movement. During the last three months, he lost very much blood per rectum, accompanied with protrusions and pain at every defecation. These protrusions did not return by themselves; he had to return them by hand. He now complained of bleeding per rectum regardless of stool. He also complained of dizziness in the head for the past month, had noises in the head, and felt faint, and weaker every day. Examination showed a man very pale and anemic, face waxy in appearance, could hardly sit up without getting faint and dizzy, seemed very feeble and exhausted, had a cadaverous look as if suffering from malignant disease. Proctoscopic examination revealed nothing above an inch from the anal opening. The rectum and sigmoid were normal, with the exception of the pale look of the mucous membranes. Anorectal examination showed large and distinct ulcerated internal hemorrhoids, which bled freely on straining. He was in no condition to be operated on. Blood examination showed red cells 3,100,000, hemoglobin thirty-five per cent. Dr. G. I. Miller gave him a blood transfusion of 500 c. c., September 9th. Doctor Wolf did not think it advisable to transfuse more, for fear of causing a too sudden dilatation of the heart. September 12th, the bleeding was so intense that I thought it advisable to operate, and owing to his weak heart, I performed the ligature operation under local anesthesia of quinine and urea hydrochloride solution 0.33 per cent. He was also placed on tonic treatment. He walked down from the operating table; the next day he was walking about, and had a fecal movement. He had no pain during or after the operation, and had a painless fecal movement daily afterward, without trace of blood. He left the hospital a few days later, and was asked to report for a blood examination; on September 20th this showed red cells 4,400,000, hemoglobin forty-seven per cent.

Case III. Mrs. C. R., aged forty-five years, referred to me by Dr. A. Goldstein, gave a history of constipation and protrusions for the past fourteen years, accompanied with blood at every stool for the past two years. During the past two months she noticed severe bleeding with every stool, which left her weak and faint, also protrusions, which she had to return by hand. Four days before I saw her, she had noticed on straining during defecation, protrusions the size of her fist, which gave her severe pain and which she could not return. She had to be helped to bed, and had had continuous pain since. Examination showed prolapsed and ulcerated internal thrombotic hemorrhoids, partly gangrenous, external thrombotic hemorrhoids, large skin tags, and a lipomatous growth the size of a pigeon's egg growing from one of these skin tags; the entire mass was the size of a man's fist, and there was

*Presented to the Eastern Medical Society, October 13, 1916.

a continuous oozing of blood. She was very weak and anemic, mucous membranes profoundly blanched, almost white, face waxy, yellow, and cadaverous. She refused to go to the hospital for transfusion, and begged just to get some relief from the pain, since she had not slept in four days. Hers was a cardionephritic case, so under quinine and urea hydrochloride 0.5 per cent solution, she was relieved of her condition and then put on tonic treatment and dilute hydrochloric acid, which seemed to have a wonderful effect in arresting bleeding from the rectum.

She has had a daily bowel movement regularly since the operation, without any blood, has had no pain during or since the operation, and was out of bed on the third day. She is slowly improving, but is not yet sufficiently strong to be permitted to go out of doors alone.

The points of interest that suggest themselves are:

1. All cases with a history of bleeding from the rectum should receive a thorough rectal examination; although slight bleeding may point to some malignant growth, yet severe bleeding from the rectum, with much loss of weight and cachexia, does not necessarily mean cancer.

2. No physician should allow a patient complaining of bleeding from the rectum to get into as weakened a condition as these did without insisting upon operation.

3. Attempts at temporary relief of rectal bleeding, or checking by means of astringent salves or powders or suppositories, with the hope of obtaining a cure, is poor practice.

4. Bleeding from ulcerated internal hemorrhoids may produce such complete exsanguination that transfusion becomes a necessity to save life.

5. Operative interference under local or general anesthesia, and removal of the cause of bleeding should be advised as early as possible, thereby saving the patient much agony and suffering, and obviating the danger which is apt to follow local or expectant treatment.

INTERNAL HEMORRHOIDS.

Their Operative Treatment Under Local Anesthesia,

By Arthur A. Landsman, M. D.,
New York,
Assistant, Department Rectal Surgery, Post-Graduate Medical School; Deputy Surgeon, Diseases of the Rectum, O. P. D., New York Hospital; Etc.

It is good ethics as well as sound common sense that the first means to be considered in correcting pathological conditions should be such as give promise of accomplishing the result, without subjecting the patient to unnecessary danger, pain, or detention from business; only when these are exhausted, or appear to be unsuitable, is the physician justified in resorting to others which may interfere with the patient's happiness, or endanger his life.

To advise operation when it is possible to cure without, shows poor judgment, and is besides an injustice to the patient; to subject a person to the uncertainties of general anesthesia when it is perfectly feasible to carry out what measures we have in mind without it, is unfair, and justly deserving of criticism.

There are many people suffering from hemorrhoids, who either do not require an operation, or in whom there are definite contraindications. It is common experience to find persons approaching middle age with one or two small piles, which give rise to no subjective disturbance whatever. There are others, and they constitute the majority of the sufferers from this affection, to whom complete cure may be promised, in competent hands, without resort to general anesthesia, and without great pain.

We are bound to admit that in the most advanced cases, when there are fully developed tumors and organized masses nothing short of radical removal will effect a cure. But in the milder ones, a great deal may be done to relieve troublesome symptoms and secure comfort, by a judicious combination of local and constitutional measures. It may be broadly stated, without going into much detail, that regulation of the bowels, the adoption of a suitable diet, the avoidance of excesses and stimulants, the use of cold baths and enemata, will go far toward making the patient's life comfortable. Such persons may go along for years, leading an untroubled existence, until some indiscretion excites an acute attack, and causes them to seek operative relief.

What factors should guide us in advising operative treatment for hemorrhoids?

1. The possibility of the development of complications which would threaten the patient's life. Ordinarily there is no immediate danger to life from hemorrhoids, but there are cases on record of sudden death from uncontrollable hemorrhage from piles; Mummery and Joski (1) cite the case of a man of forty-three years, who on his admission into the hospital, was found to have strangulated hemorrhoids with thrombosis of the anal veins extending upward two inches, which resulted in sloughing of the entire rectum and death of the patient.

2. Hemorrhage in small amounts, occurring over long periods. Some piles may never bleed, others ooze constantly, once they become ulcerated, and bleed freely when the patient strains at stool, or makes any unusual exertion. There is a decided tendency for hemorrhoidal tumors to become ulcerated from a disturbance of their nutrition and from friction of hard stools, with resulting bleeding and secondary anemia. Patients are not uncommonly seen in rectal clinics, who have been bled white from loss of blood from ulcerating piles; clearly if such exhausting drains are unchecked, grave consequences must ensue.

3. Pain from thrombosis, inflammation, or strangulation of piles may be so excessive as to become unbearable. Pain is an important factor in shock, and animals in which it has been produced experimentally show organic changes in the Nissl bodies, absence of hyperchromatic cells, and disintegration of the nuclei of the multipolar cells of the cerebellum (2). Pain is relative, and persons react to it differently. The phlegmatic Chinaman and the excitable European do not suffer alike, yet there are few people who can stand pain in the anal region with philosophical resignation. The pain from acute affections of the lower portions of the anal canal is exquisite, often entirely out of proportion to the size of the lesion. This need occasion no surprise, if we remember the rich sensory supply of the anus and perianal region, and the fact that the nerves com-

municate with each other freely, hence a painful stimulus sets up a reaction in a wide area. They radiate toward the anus from the anococcygeal nerve, the inferior hemorrhoidal, deep branches of the perineal, perforating branches of the second, third, and fourth sacral, and the long perineal branch of the posterior cutaneous nerve of the thigh. Their fibrils interlace and provide this portion of the body with a network of nerves which is a revelation to the man who dissects the anoperineal region carefully. Furthermore, lesions of the anal canal are likely to set up spasmodic contractions of the sphincters from a reflex disturbance of the nervous mechanism, extremely distressing in a portion of the body which moves with every change in the abdominal pressure.

4. Sloughing and gangrenous internal hemorrhoids from strangulation of the blood supply, require surgical treatment. Some years ago an eminent gastroenterologist (3) seriously recommended a cure for hemorrhoids which was based on the amputation of the mass by sloughing, after it was drawn out with a Bier cup and caught in the external sphincter. It must be obvious that this method of curing a surgical condition is painful, uncertain, and unscientific, but it may not be generally known that it is likely to be dangerous as well. In children and emaciated persons, the bottom of the rectovesical pouch may be as low as one inch from the anal margin, in which case the patient would be exposed to serious danger of infection of the peritoneal cavity by direct extension of the inflammation from below (4). It certainly seems more rational to use clean cut surgical methods, when we can, which enable us to a large degree to control and limit the extent of the inflammatory process.

5. A person suffering from hemorrhoids faces the possibility of abrasion and ulceration of the mucous membrane, with the development of abscess, fistula, phlebitis, fissure, stricture, etc. Prolapse of the bowel caused mechanically by the traction of hemorrhoidal masses is not infrequently noted as a complication. It is good surgery to remove a condition which is fraught with inherent possibilities of so much mischief.

Contraindications to the operation are obstructions to the portal circulation from cirrhosis and irremovable tumors, advanced pulmonary, cardiac, or nephritic disease, diabetes which cannot be made sugar free, chronic alcoholism with nervous complications, hemophilia, purpura hæmorrhagica, icterus, and blood states accompanied by diminished coagulation. The first and last months of gestation and the first week of the puerperium are obviously unsuited for any operation on the rectum which may be delayed.

If we now decide that operation is necessary, it is more than likely that our patient will want to know whether he cannot be cured without "taking ether"; indeed this is a very important question for him. Local anesthesia is inapplicable to children, or adults of a highly neurotic temperament, subjects with a congenitally small or tight anal canal, or such in whom the tumors are high up, and cannot be brought down within reach. Generally speaking, all external, and about ninety per cent. of internal piles may be removed painlessly and treated successfully under local anesthesia.

It is true that the danger from the inhalation of most general anesthetics is slight, but there is a mortality, and it adds one more element of risk which the patient must face. If we assume that there is one fatality in 20,000, that one may be your patient, kinsman, or dear friend, and there is no mortality from a nontoxic local anesthetic. In addition, operations under local anesthesia are not followed by the usual postanesthetic discomforts, reflex urinary disturbances, or ill effects on heart, kidney, or lungs, and need cause but trifling detention from one's regular duties.

Of the agents used for local anesthesia in rectal practice, cocaine, betaeucaine, novocaine, and quinine and urea hydrochloride, are best known. The three former possess the advantage of producing efficient anesthesia very promptly, but they are toxic, do not keep well in solution, are expensive, and their use has been followed by bleeding from secondary relaxation of the bloodvessels. The double salt of quinine and urea, in one per cent. solution, is not open to any of these objections, and its effect is prolonged from seven to eight hours to as many days, an obvious advantage in the aftertreatment of rectal patients. It has been studied by Hertzler (5) and extensively used by Hirshman (6), the former of whom attributes its action to a deposition of a granular fibrin on the nerve endings, and asserts that the anesthesia lasts until this is absorbed. It has been urged against it that it retards healing and causes sloughing of the wound, results which those who have had a wide experience with it will by no means concede.

Gant introduced the use of sterile water, which is worth remembering in an emergency, as tap water is obtainable everywhere. It acts by pressure on the terminal filaments of the nerves, but its action is fleeting and uncertain; he has abandoned it for eucaine 0.25 per cent., which is in this dilution practically nontoxic, and a thoroughly dependable local anesthetic.

There are various methods of operation, all of them designed to destroy the tumors, or get rid of the pilebearing area; some by crushing, burning, injection of irritating substances, electrolysis, excision, and what not. None of them present the simplicity, effectiveness, and freedom from complications of the ligature operation. The patient is prepared by the administration of a physic the day before the expected operation, and an enema of a pint of boric acid solution two hours before. He is placed upon the table in the left lateral position, with legs flexed on thighs, and thighs on abdomen, with his back to the source of light. The parts are thoroughly cleansed with soap and warm water, and the anal canal is swabbed with cotton plugs saturated with a mild antiseptic. An assistant holds the buttocks apart, while the patient is told to bear down, which is usually followed by the protrusion of the hemorrhoidal masses; if any difficulty is experienced in bringing them out, he is directed to strain down in the squatting position, or is given an enema of a pint of glycerin and warm water. The pile tumors are thoroughly anesthetized with quinine and urea

in one per cent. solution, by slowly injecting the fluid into each tumor until it is blanched and stands out prominently, and a hemostat is clamped on it at the point of puncture, in order to prevent the solution from oozing out. The drug is absorbed slowly, and at least twenty minutes must be allowed to secure a complete effect. The mass is then pulled down by gentle traction on the hemostat, to include any redundant tissue, which should be ligated off with the pile, and mucous membrane dissected off from its distal end, well tied with a strong silk or linen ligature, the part above it cut off, and all the other masses treated similarly. We tie the knot tightly to prevent bleeding, and leave a good sized stump in order to prevent slipping of the ligature. A thin strip of gauze, dipped into sterile oil, is introduced into the rectum to keep the raw edges apart and prevent agglutination, but the anal canal is not packed, as that would interfere with free drainage. It is not needed if the work has been done carefully, while its removal, after granulations have grown into the meshes of the gauze, inflicts unnecessary pain.

The writer does not pretend to describe an original operation, but simply to give an outline of the method in use in one of the largest rectal clinics in this city for the past fifteen years, a method which has been gradually simplified so that it does not require an elaborate technic or many assistants, consumes but little time, needs but few instruments, is painless in execution, and gratifying in its final results.

The patient leaves for his home after a period of rest, to present himself at the clinic every second day for a week, thereafter at longer intervals until the wound is healed. The bowels are moved on the third day by a dose of castor oil, and when the desire for stool comes on, an injection of a little olive oil.

The aim of the postoperative treatment is to conserve the patient's strength, induce rapid healing, and prevent complications. These do not occur frequently, but occasionally we meet with secondary bleeding, delayed healing from protracted ulceration, chronic fissure, sloughing, abscess or fistula, sepsis, acute phlegmonous periproctitis, dysuria, postoperative stricture, and incontinence.

Secondary bleeding was not uncommon in the days when the clamp and cautery and crushing operations had their vogue, and was caused either by the loosening of the clot which sealed the bleeding vessels, or by a portion of the tissue which was to have been burned slipping away from the clamp and being incompletely cauterized. It is rarely seen after the ligature operation, and only if the stump has been cut off too short, or the knot poorly tied.

Delayed healing from chronic fissure or protracted ulceration may be the result of constitutional conditions, such as syphilis, chronic nephritis, diabetes, or tuberculosis, or a choice of a poor operative method, as seen on the Continent, especially in Italy, where the Whitehead operation still enjoys a strong following.

Abscess, fistula, and general sepsis are in most instances preventable complications, so far as they are caused by faulty asepsis; it must not be forgotten, however, that we are dealing with an operative field which cannot be properly sterilized, and it is really surprising that infections are not more common.

Acute phlegmonous periproctitis is a formidable complication which leads to rapid destruction of the soft parts of the anorectal region, and to the death of the patient from exhaustion and septic poisoning. Traumatism and operations about the rectum are mentioned as causes by the older writers, but it is more probable that it is an infection by a malignant strain of streptococcus, which, according to the recent studies of Rosenow, may assume added virulence by reason of a favorable environment.

Dysuria is a temporary condition, a reflex phenomenon from the nerves which supply the levator ani, whose anterior fibres find their insertion in the urethra and prostate.

Stricture of the anal canal is due to free removal of the perianal skin with resulting contracture from scar tissue, cutting away too much mucous membrane, ulceration following the Whitehead operation, or faulty aftertreatment.

Incontinence is an unfortunate sequel of an operation for the cure of hemorrhoids, and is generally traceable to permanent damage of the sphincters from forcible tearing of their fibres by unskillful dilatation.

Recurrences are not common, but our duty to our patient is not ended until we have given him a word of warning in regard to the prevention of similar trouble in the future. If the same influences which caused the disease in the first place continue to exist, there need be no surprise if other venules of the lower anal canal in time become the seat of dilatations and varicosities. He should therefore avoid conditions which are responsible for hemorrhoids in subjects predisposed to them, such as constipation, straining from any cause, the habitual use of strong or irritating purgatives or enemata, indiscretions in diet, excesses in stimulants, etc. These have a tendency to weaken the resistance of the bloodvessels by constant engorgement and excessive pressure in their walls, particularly when they are already defective from hereditary or environmental conditions.

It must be evident from what has been written that an operation for the cure of hemorrhoids is by no means the simple matter it is sometimes made out to be, but an important surgical procedure, which in all cases ought to be intrusted only to those who are skilled in the surgery of the region, and experienced in avoiding its many pitfalls.

Malignant Pustule and Neosalvarsan. — F. Heim (*Correspondenz-Blatt für schweizer Aerzte*, September 30th) reports a case of malignant pustule which was not arrested by local treatment. The patient's temperature continued to rise, and his general condition to grow worse, until 0.45 gram of neosalvarsan was injected into his veins; improvement followed immediately.

HARD WATER AND HEALTH.

A Critical Review,

By Frank Leslie Rector, B. S., M. D.,
New York.

The place occupied by water in the economy of life is one of first importance. Approximately seventy-five per cent. of the human body is water, varying from two per cent. in the teeth, to ninety-nine per cent. in the blood. The amount ingested should reach two quarts daily, but few people take this quantity. It is an important constituent of food, and plays no small part in digestion. Henderson (9) says:

> Water is ingested in greater amounts than all other substances combined, and it is no less the chief excretion. It is the vehicle of the principal foods and excretory products, for most of these are dissolved as they enter or leave the body. Indeed, as clearer ideas of the physicochemical organization of protoplasm have developed, it has become evident that the organism itself is essentially an aqueous solution in which are spread out colloidal substances of vast complexity. As a result of these conditions, there is hardly a physiological process in which water is not of fundamental importance.

Its value in Nature is attested by its almost universal presence upon the surface of the earth, there being few places where it cannot be obtained, either from the surface or from a variable distance below the surface. This enormous volume is what is termed natural water, formed by the falling rain which comes in contact with the soil and subsoil, dissolving certain salts which are carried with it in its subsequent journeys. All natural water holds salts in solution in greater or less quantity, and the only way these salts can be separated from the solvent is by distillation, a process which gives an artificial product quite different in composition and taste from that of the original product.

We are told by some that the use of this natural water, if it contains any considerable quantity of chlorides and elements which make up the hardness of a water, viz., the carbonates and sulphates of calcium and magnesium, will exert a harmful effect upon the human economy, and lead to serious physical derangements. Others would dismiss this contention by saying that if the Almighty had planned for the life of the universe to depend on water containing no minerals He would have provided such a supply; and that as such a water is unknown in nature the use of an artificial product is not according to Divine intent. There are undoubtedly good arguments for such a line of reasoning. The writer desires, however, to discuss this question rather from a scientific standpoint in the light of present day knowledge of the subject.

Modern scientific laboratories are able to duplicate synthetically almost any substance found in nature. It is even possible to analyze the protoplasmic cell, determining its various chemical constituents. But after all these constituents have been assembled again in their proper proportions, we do not have a living cell. The elements are there, combined as nearly as possible in the way we found them; but that subtle *something* necessary to stimulate the assembled material to action, and which we call *life*, is lacking. It is not tangible, it is not visible, it is not capable of analysis, yet it provides the necessary vital force for the proper functioning of that particular combination of chemical elements.

We find the same thing true when dealing with natural and artificial waters. In Nature's laboratory, the life cycle, so to speak, of vaporization, cloud formation, rainfall, and contact with the earth, has wrought changes which defy the ingenuity of man to duplicate. We can produce the same thing chemically just as we can produce a cell chemically, but the vital, subtle, *something* which gives a natural water its characteristics has remained up to the present time locked in Nature's storehouse safe from human knowledge.

In searching the literature we find that advocates of distilled water are pretty generally those whose environment precludes the use of any other, except at occasional times; naval men, seafaring men, and military men serving in the tropics comprise this group. Not all military men are of this opinion, for Davis (6) says: "From long experience I am convinced that the constant use of boiled or distilled water is not conducive to health."

The writer believes that the medical profession, as a whole, are pretty well agreed that the constant use of an artificial water is not best for our general health. Distilled water has its place in the treatment of disease, and that place is usually filled in the compounding of prescriptions. There are few diseases in the treatment of which distilled water is indicated.

On account of the ease with which distilled water becomes contaminated, large numbers of bacteria are frequently found. Barladean (2) says: "Mueller examined sixteen samples of distilled water from various pharmacies and found only two in which the germ content was less than 100,000 per c. c. One contained 6,050,000, and two over 700,000 per c. c."

The health of the American navy is frequently pointed to as evidence of the value of distilled water in the human economy. But can the condition of this group be attributed solely to the use of distilled water? In the first place, the great majority of the men of the navy are young, vigorous, and strong, being selected only after passing a rigid physical examination. They are the pick of the country from a physical standpoint. Less than twenty per cent. of the applicants for service in 1915 were accepted. On page 12 of the *Annual Report* of the Chief of the Bureau of Navigation to the Secretary of the Navy for the fiscal year 1915, we find: "There has been no trouble in getting applicants for enlistment. Only about one sixth of these, however, are accepted, as the navy will have only the best of the young men of the country." Their term of enlistment is for only three or four years, and as a considerable number do not reenlist, fresh vigorous recruits take their places.

From the report quoted above we find that nearly twenty-two per cent. of the men in the naval service are serving their first year of enlistment, and that approximately this proportion is added each year. While in service the habits and modes of life of the enlisted men are so rigidly controlled

that they are kept up to the highest efficiency by plenty of exercise, and the proper regulation of their habits. By immunization they are protected from typhoid fever and other diseases which so often play a large part in undermining the health of an individual. The short period of enlistment of the average sailor, combined with his regular habits, gives insufficient time for the development of permanently unfavorable conditions. While the service of naval officers is longer than that of the men, the same argument holds good in their case.

Von Wedekind (20) attributes the physical condition of the men to the fact that only distilled water is used in the navy for cooking and drinking purposes. He says: "I am urging strongly that the rest of the world live as we do, some 70,000 strong, using distilled water for cooking and drinking, and live on and on, youths at sixty-five. We do not have arterial degeneration, gout, and rheumatism, though not surrounded by home comforts, regular seasons, regular amusements, and home life." In connection with this statement the following table, compiled from the *Annual Reports* of the Surgeon General, U. S. Navy, for the years indicated, may be of interest.

TABLE OF OCCURRENCE OF CERTAIN DISEASES IN THE U. S. NAVY DURING FOUR CALENDAR YEARS 1911-1914.

	1911	1912	1913	1914
Total Force	61,399	61,897	65,926	67,141
Rheumatism (all forms)	819	700	614	702
Arthritis	163	105	80	138
Arteriosclerosis	2	10	10	8
Goitre	0	1	18	20

Deductions drawn from a study of highly restricted and specialized groups cannot be applied with fairness to the entire population, surrounded as it is with a variable and ever changing environment.

Jackson (10) believes that it is much better to drink soft water. He says: "The lime salts in the waters which are drunk are not utilized physiologically as far as known." Just why the lime of water should not be utilized by the system and that contained in other foods as milk, meat, and vegetables should be useful to the bodily upkeep is not made clear by Jackson. The writer believes that these salts in water are used as in any other food product, and being in solution are much more easily absorbed.

The statement that a natural water that is mineralized to a considerable degree is not beneficial to young children, is not borne out when we consider that milk, a food admitted to be the one perfect food for children, contains many times as much lime as does a water classed as hard. Under ordinary conditions milk is prescribed in unlimited quantities and its use by young children is encouraged as fully as possible.

Many authorities in expressing views upon this subject maintain that a hard water is beneficial to health, or at least is not injurious; and some show the harmfulness of distilled water. Ogden (13) says:

> No water, as used for drinking purposes, is absolutely pure, according to the standards of chemistry. Distilled water is the nearest approach to pure water obtainable, and it is said by physicians that such water is not desirable as a habitual and constant beverage. The human body requires certain mineral salts, particularly for the bones and muscles, and while these salts are provided in a large measure by food, a number are also furnished by drinking water.

Mason (12) in discussing the question of drinking water and disease says that the minerals that give to the water the characteristics known as "hardness" obtain to a greater or less degree in every public supply:

> As to the wholesomeness of such a water, there is widespread opinion that a high degree of hardness is not compatible with safety; but although hard waters do often produce certain intestinal derangements in persons not accustomed to their use, there are no sufficient statistics on record tending to confirm the popular belief that they lead to the formation of urinary calculi.
>
> As has been pointed out by Professor Drown, the waters of the south of England are excessively hard, but the statistics do not show an increase of death rate resulting therefrom.
>
> The English Rivers Pollution Commission (*Sixth Report*) collected statistics from towns of the same character having hard and soft water supplies. Twenty-three towns with soft water supplies had an average death rate per 1,000 of twenty-six; while in forty-three towns supplied with hard water the average death rate was 23.5. The commission concluded that: "Where the chief sanitary conditions prevail with tolerable uniformity, the rate of mortality is practically uninfluenced by the softness or hardness of the water."

Mason concludes the discussion of the relation of drinking water to goitre by saying that: "Our present knowledge upon the subject is, therefore, in a very unsatisfactory state, except in so far as we may be assured that the chemical ingredients of a water cannot be held to be goitre producing."

According to Woodward (21), "Considerable diversity of opinion has been expressed on the relative merits of hard and soft water for drinking purposes, but statistics relating to health in many localities where supplies of hard and soft water are used do not indicate any noticeable difference in the death rate." He says further: "The notion that chalk water is liable to produce gout or calculus is a fallacy"; and that "soft waters are more apt than hard waters to take up organic impurities; therefore a moderate degree of hardness is generally to be commended in a potable water."

Berg (3) concludes that the harder the drinking water of a district, the better the physical development of the children. The conclusions were drawn principally from the examination of the condition of the teeth. The composition of the saliva was also studied with reference to the effect of drinking waters of varying hardness, and diets containing varying amounts of calcium. It was found that the amount of saliva excreted increases with the hardness of the water, and children who habitually drink hard water secrete a saliva both relatively and absolutely more alkaline than is the case with children in neighborhoods supplied with soft water.

Lewis (11) discusses the arguments which have been advanced both for and against the use of hard drinking water. In speaking of goitre he says: "Melted snow water is supposed commonly to exert more influence in the causation of this disease than any other waters, however hard."

Other argument advanced by Lewis against the use of hard waters are the astringent and desiccative action of calcium salts upon the skin, the formation of urinary calculi, and the production of arteriosclerosis; all of which he dismisses with the

statement that there is no evidence to prove the contention.

He then considers the evidence in favor of the use of hard waters, among them the fact that Nature had provided four fifths of the earth's surface with hard water which was pretty good evidence that it was harmless; that hard water was less easily contaminated than soft; that it was far preferable for growing children to soft water; and concludes his article as follows: "To sum up, then, there is no evidence that hard water has any bad effect; on the contrary, all the evidence is the other way."

Thresh (19), in his work on water supplies, says: "There is no evidence whatever to show that moderately hard waters have any influence whatever upon health." He quotes Doctor Cartin, medical officer to the Eastern and Western Telegraph Companies, as stating that at several of their stations in warranted in saying and maintaining that a high solid residue in drinking water can have no very markedly injurious effect on public health.'"

Coles Finch quotes from the *Lancet* as follows:

It is a popular, but probably wrong, impression that hard drinking waters are prejudicial to health, and moreover are injurious to delicate skins when used regularly for ablutionary purposes. Gout, kidney disease, and dyspepsia, by an interesting line of reasoning, have been supposed to be due to, or aggravated by the drinking of excessively hard water. Some mysterious connection between the chalk of the water and the formation of "stone" in the kidney, or of "chalk" in the joints, in gout, is a favorite speculation with many; but in the history of the world's water supplies there is no trustworthy evidence that the drinking of hard water influences for the worse these diseases. The idea is, in fact, chimerical.

Gammage (8) in discussing the relation between water hardness and health says: "The consensus today seems to be that in similar class towns having

[1]Album of the Spas and Mineral Springs owned by the Royal Prussian Board of Domains.

tropical climates where the only water available is distilled water, the teeth of the men are seriously affected. This difficulty was overcome by adding both lime and salt to the water.

Thresh also states that: "A French commission arrived at the conclusion that a moderately hard water was the best, and that persons residing in districts supplied with such water had a better physique than those living in districts where soft water was used; and a Vienna commission expressed the same opinion."

Coles Finch (5) has this to say regarding the subject of hardness and its influence upon health: "I am of the opinion that hard water is beneficial to the human system to a far greater extent than we are generally aware, especially to children and young people, the lime in the water helping to build up their frames. Children cannot drink too much of this water; for as has been noted in hard water districts the absence of rickets is apparent, and the inhabitants generally have better teeth than those living in soft water districts. If this is so, the whole frame must also derive an equal benefit, though not so apparent."

Again he says: "Wanklyn, in his practical treatise on water analysis, says: 'The Metropolitan water contains four or five times as much solid matter as the Manchester and Glasgow waters. The healthfulness of London is higher than either, and I am like principal sanitary conditions, the death rate is not raised or lowered by the softness or hardness of the water." From a study of his data Gammage concludes that: "Neither in the individual results nor in the group results is there enough consistency to say that hard waters are more destructive to life than soft waters."

Dole (7) cites analyses of waters containing solids up to 5,000 parts in the million which have been used for years for all domestic purposes without noticeable ill effect. He sums up his conclusions by saying: "The amount of inorganic matter that may be present in drinking waters without having appreciable physiological effect is comparatively great."

If natural water containing salts in comparatively large quantities is so harmful as some would have us believe, why are physicians continually sending patients to American and foreign spas for treatment? The waters at these various places contain from hundreds to thousands of parts in the million of solids, mostly carbonates, sulphates, and chlorides, yet they are prescribed freely for gout, rheumatism, arteriosclerosis, kidney and urinary disorders, etc. Our own Saratoga waters, and such foreign waters as Ems, Fachingen, Langenschwalbach, Vichy, Folkstone, and others are classed as valuable medicinal agents in alleviating the unhealthful conditions mentioned.

The following tables give the sulphates, chlorides, bicarbonates, and total solid content of some of the better known American and foreign waters that are used and recommended by physicians in the treatment of disease. No attempt is made to include all sources of this nature, and those given are for illustrative purposes only. Tens of thousands of patients visit these spas each year solely for their curative effects. Thompson (18) is authority for the statement that Kissingen alone is visited annually by more than 34,000 patients, and that upward of 1,600 American patients have been in the habit of going to Nauheim each year.

Of the diseases usually attributed to the use of hard water, arteriosclerosis, rheumatism, gout, goitre, and various renal affections are the most prominent. In the table of foreign spas noted above, almost without exception the water is recommended in one or more of these diseased conditions; while the report of the commissioners of the State Reservation at Saratoga, for 1913, says that rheumatism, arteriosclerosis, and renal diseases have been benefited greatly by a course of treatment at these spas.

TABLE II, SHOWING COMPOSITION OF AMERICAN WATERS, SARATOGA SPRINGS.[1]

Name	Chlorides P. P. M.	Sulphates P. P. M.	Bicarbonates P. P. M.	Total Solids P. P. M.

[1]Report of the Commissioners of the State Reservation at Saratoga Springs, 1913.
[2]Bulletin 98, Bureau of Chemistry, Mineral Waters of the United States.

Such men as Osler, Anders, Hare, Stevens, and others recommend spa treatment. Osler (14), in speaking of the treatment of arteriosclerosis, says: "The use of mineral waters, or a residence every year at one of the mineral springs is usually servicable"; and of rheumatism: "A residence at Bath, England, the Hot Springs of Virginia, Arkansas, or Santa Rosalia, Mexico, or at Banff, in the Rocky Mountains, on the Canadian Pacific Railway, will sometimes cure even obstinate cases."

Anders (1), on the treatment of rheumatism, says: "The thermal springs whose waters are alkaline or contain sulphur, and of which the hot springs of Arkansas and Virginia, and the Richfield Springs, New York, furnish good examples, have been strongly advocated, and sometimes prove curative in their effects." Of gout, he says: "Mineral waters, particularly the alkaline, are highly advantageous, and sometimes curative. Their value, like that of warm baths and systematic exercise, is dependent upon their power to increase renal elimination."

Stevens (17) says regarding the treatment of gout: "Visits to certain mineral springs, Bedford, Saratoga, Harrowgate, Carlsbad, Contrexéville, Aix-les-Bains, are sometimes of greatest value."

In a recent admirable article, Bolduan (4) discusses the cause of arterial degeneration, Bright's disease, and apoplexy, under the heads of alcohol, tobacco, syphilis, chronic poisons, social environment, sex, age, etc. At no time does he mention the influence of hard water, and concludes that the preponderating cause is syphilis.

The argument that too much lime is taken into the system in a hard water has been answered partially in reference to the use of milk by children. Furthermore, the average therapeutic dose of lime is about sixty grains a day. A hard water is usually spoken of as one containing 200 parts in the million or more of lime. Therefore, in order to obtain a therapeutic dose of lime from such a water it would be necessary to drink six gallons in twenty-four hours, a feat difficult of accomplishment by the average person. A common glassful of such water would contain approximately three fourths of a grain of lime.

This is analogous to the statements of the lithia water adherents, who assert that the spectroscopic traces of lithium found at times in a water renders it a panacea for various and sundry diseases. There are various court records where this question was involved where it was shown, in one case, that in order to obtain a medicinal dose of lithium it would be necessary to drink 1,000 gallons daily; in another case, the amount consumed would have to totalize 100,000 gallons daily in order to meet the therapeutic requirements for the administration of lithium!

In summing up, then, it seems to the writer that the weight of authoritative evidence is in favor of the use of a natural water containing a moderate amount of mineral, at least enough to avoid the flatness in taste of distilled and soft waters.

Specific and Other Forms of Spondylitis.—B. Sachs (*American Journal of Medical Sciences*, November, 1916) says that the specific cases of spondylitis should be treated most vigorously with intravenous injections of salvarsan, combined with intramuscular injections of mercury, or inunctions. The nonspecific cases must be treated either by rest, by intense heat, or by orthopedic measures.

PARENCHYMATOUS GLOSSITIS.*

With Report of a Case.

By Max Lubman, M. D.,
New York,
Associate Otologist, Har Moriah Hospital.

Case. Miss M. S., nineteen years old, became ill on March 8, 1916. Family history, negative. Past history: Had influenza two years ago. On March 8th, she went to bed in good health. About 4 a. m., on March 9th, she awoke with pains in the neck, back of the head, and throat. The pains were aggravated by talking or swallowing, and she felt feverish. Early in the morning, the left side of her tongue became swollen and painful. During the day, the right side of the tongue also became swollen. Speech was painful and swallowing impossible. She was unable to close her mouth. Temperature was 103° F., pulse 100. The case was referred to me on March 10th by Dr. Charles J. Mark. The patient wore an anxious, pitiful expression. Her voice sounded as though affected with a double quinsy. Speech came with great difficulty and was very hard to understand. The tongue protruded from the mouth, dribbling saliva. Temperature by rectum was 103° F., pulse 106. Upon examination the tongue was found to be uniformly swollen on both sides and very tender to the touch. It had a leathery consistence. With great difficulty I inspected the tonsils, pharynx, and the larynx, which were negative. The salivary glands were neither involved nor tender to the touch. The cervical glands were not involved or painful. The examination of the nose was also negative. A diagnosis of parenchymatous glossitis was made. The treatment hereafter outlined was prescribed, resulting in a complete recovery.

Etiology. The disease is noticed mostly during the winter months, and attacks males more frequently than females. It occurs chiefly between the ages of twenty and forty years, though A. B. Bennet (1) states that cases have been reported at the respective ages of nine months and eighty years. The disease is quite infrequent. Butlin (2) says: "Acute inflammation of the tongue is admitted by all to be a rare disease. Even the largest hospital in this country (England) does not in many years record a single case. It appears to be occasionally endemic (Fleming, 3) and at times epidemic (Reil, 4). It is difficult to state the direct etiological factor. Undoubtedly there must be some predisposing and some exciting causes. Still idiopathic cases occur where no cause can be found. The sudden or prolonged exposure to atmospheric changes, i. e., to cold and moisture as when working in damp and wet localities, is often the apparent determining cause. Graves (5) relates a case of Dr. Nelgian, in Jervis Street Hospital, in 1846, which serves to substantiate this etiological factor. It happened to a stout villager, forty years of age, who, engaged in draining a river, worked for several days in water up to his waist. The affection came on with rigors and ordinary symptoms of fever. The entire tongue became enlarged and so enormously swollen as to prevent articulation, swallowing, or the cleansing of the throat. Still he reports another case where there was no exposure to wet at all. The case is as follows: Mr. B. A., a medical student, was laboring under febrile symptoms for an entire week, ushered in by violent rigors and great pain in the neck and occiput; he was somewhat relieved on the second day by a profuse epistaxis. The left half of the tongue was gradually increased in size, then became very tender and painful. The tongue was enormously swollen and nearly filled the entire cavity of the mouth, which could scarcely be closed on account of the protrusion of the tongue. The right half of the tongue was perfectly normal, and its comparatively diminutive size formed a striking contrast with that of the left, the median line forming a perfect boundary between the swollen and healthy sides.

In some cases, it seems, glossitis may be produced from a reflex, as the following two cases will illustrate: Dr. R. Lewis (6) reports a female, forty-eight years of age, who was being treated for a chronic suppurative otitis media complicated by excessive granulations. The woman was in average good health, with no hysterical tendency. After the third application of chromic acid, the patient complained that during the night following the treatment her tongue began to swell, and that for a few hours it was very difficult for her to breathe. The condition passed away without treatment. Six hours later another application of chromic acid was made to the ear, and in thirteen hours the tongue began to swell so rapidly that in two hours she could not protrude the tongue, nor could the jaws be closed, the swollen tissues interfering so greatly with breathing that tracheotomy was seriously considered.

Dr. Frank C. Raynor (7), of Brooklyn, reports a case of parenchymatous glossitis following a submucous resection: H. H., aged twenty-six years, single, American, was first seen in the Brooklyn Eye and Ear Hospital Clinic on November 12, 1914. An examination showed the septum deviated anteriorly to the right, and posteriorly to the left. Submucous resection by the house assistant on November 16th; dressed on November 17th. Seen again on November 20th and apparently doing well. On November 22nd patient awoke with "a sore throat" which grew worse during the day, so that he was unable to swallow. He consulted a local physician, who prescribed a gargle. Continuing to grow worse, he applied to the hospital and was admitted on the evening of November 23rd. Examination disclosed the tongue greatly swollen, completely filling the mouth, and protruding dry and coated; the patient was unable to swallow anything. There was no associated stomatitis, and the pharynx, so far as inspection allowed, showed no infection. Axillary temperature was 103.4° F. He complained only of slight tenderness on pressure over the submaxillary glands. On November 24th, at 3 p. m., temperature was 103° F.; culture taken from the tongue near the frenum, which was somewhat abraded from contact with the teeth, proved the infection to be streptococcus.

It may also be of interest to mention a case related to me by Dr. A. M., of New York, a colleague of mine, who said that when eight years of age, in Rumania, his native land, he had parenchymatous glossitis. The physician called to attend his case said that the etiological factor of this disease was that food already partly eaten by a rat (not a mouse) must also have been eaten by the patient. Taking this as an etiological factor, we can readily understand the possibility of the disease being occasionally endemic (Fleming) and occasionally epidemic (Reil). This would also in a measure account for the rarity of the disease at the present time, because the vast improvement in our methods of living, as

*Presented at the Clinical Society of Har Moriah Hospital, April 24, 1916

well as the great care now exercised in the preservation of foodstuffs, make contamination from this source well nigh impossible.

Other etiological factors are: Jagged edges of broken teeth and carious teeth; wounds from splinters of tooth picks, spiculæ of bone, pins, and needles; wounds from teeth during epileptic seizures, and other convulsive paroxysms; the contact of the tongue with cold iron in cold weather; the contact of the tongue with acrid corrosive substances; concealed calculi in the tongue; bites and stings of venomous insects, such as the wasp and bee.

Symptoms. Symptoms appear quite suddenly, usually unilateral, even when they subsequently become bilateral. These symptoms are, at first, a sensation of heat and tumefaction of the tongue, quickly followed by stiffness and considerable impediment in its movement. The local symptoms are often preceded by rigor and followed by fever, cephalalgia, and pain in the neck and occiput. In a few hours the entire organ may become so involved and enlarged as to keep the lower jaw depressed and almost fill the entire oral cavity. The tongue projects beyond the teeth and the lips. The soft palate is lifted and the epiglottis often pressed down, making respiration very laborious. Deglutition is difficult and articulation impeded or impossible. The sublingual and submaxillary glands are seldom involved unless the lesion undergoes suppuration.

The tongue becomes very hard to the touch, the face pitiful, and the expression anxious. Sleep is disturbed, saliva dribbles externally, thirst is intense, odor from mouth fetid. The pulse as a rule is slow, ranging from 100 to 110, with a temperature of 103° to 104° F. Bowels are constipated; urine is scanty and high colored. These symptoms reach their height in less than forty-eight hours and then begin gradually to subside. Should the process begin to terminate in suppuration, the local symptoms increase in severity until the pus is evacuated.

Pathology. It has been advanced that in idiopathic glossitis engorgement of the vessels is probably a sequence of vasodilator influence of the glossopharyngeal nerve for the base of the tongue, and the chorda tympani for the anterior portion. For an instance of herpetic glossitis from probable irritation of the chorda tympani nerve by an aural polypus, see Berkely Hill (8). Pepper (9) gives the following pathology: However engendered, there is a rapid distention of the organ by blood, followed by infiltration of fibrin and serum into the intermuscular connective tissue and into the planes of connective tissue separating the muscular fasciculi.

Prognosis. The prognosis should be guarded. Bennet, however, states that of the 145 cases only four ended fatally, or less than three per cent.

Treatment. The patient should be put to bed. The bowels should be kept open, and leeches applied at the hyoid bone on each side. Small pieces of ice may be kept in the mouth to allay the thirst and the burning sensation. Wash the tongue as well as the mouth with a bland antiseptic as often as possible. Apply cold compresses around the neck. Small doses of morphine may be given if the patient's restlessness requires it. It is important if the condition does go on to suppuration, that deep incisions be made.

Abstracts and Reviews

CHEMOTHERAPY IN TUBERCULOSIS.*

By Paul A. Lewis,

Henry Phipps Institute for Tuberculosis.

The use of the term, chemotherapy, had become so loose that the author deemed it necessary to define it before proceeding to the main subject of his lecture. He said that it was in Ehrlich's sense that the term should be employed, i. e., to mean the use of an agent which possessed more or less definitely specific and selective chemical affinities for the causative organism of a disease, which affinities were inherent in the chemical relations between the substance and the organism or its constituents.

The idea of the development of a chemotherapy of tuberculosis was not new, for it was expressed by Koch and his associates, von Behring and Ehrlich, at the time of Koch's discovery of the specific organism. They then sought a means of chemical disinfection of the body invaded by the tubercle bacillus, but these efforts, as well as many subsequent ones, were unavailing. Springing from these studies, however, investigations showed that certain substances did possess far greater affinities for the tubercle bacilli in vitro than for other pathogenic organisms, and in this sense were specific disinfectants. These substances did not prove destructive to the organisms in experimentally infected animals, the failure being due to several factors, among which the most important were those of dilution and distribution, which acted to prevent the access of the disinfectants to the tubercle bacilli in the bodies of living animals, or at least their access in sufficient amounts to prove destructive or inhibitory to the growth of the bacilli.

More recent studies have demonstrated the fact that some substances are inactive as disinfectants or inhibitory agents against the tubercle bacilli in vitro, yet are active in one of these directions when administered to infected animals. The explanation of this phenomenon was probably that these substances underwent some modification after introduction into the living animal which altered their properties in the direction of converting them into active agents against the organisms.

Still a third group of substances has now been found which are possessed both of active inhibitory or disinfectant properties toward tubercle bacilli, and of distribution coefficients in the animal body which permit their reaching the foci of the bacilli in effective amounts. It was with such substances

*Summary of a lecture delivered before the Harvey Society at the Academy of Medicine, New York, November 25, 1916.

that the author and his associates had made their experiments.

The lecturer said that, to the uninitiated, experimental human or bovine tuberculous infection of animals offered an ideal set of conditions for the study of the effects of such chemotherapeutic agents. Such, however, was not the case and the scope of disturbing factors was truly enormous. Among these were the facts that experimental infections, even with the same strain, did not run a perfectly regular course; that cultures differed widely among themselves; that a given culture would change with continued propagation; that the amount and manner of the inoculations greatly modified the course; that the differences in the time of death following experimental inoculation were very great; that the post mortem lesions after spontaneous death varied greatly in distribution, extent, and type; and, finally, that the slow progress of the disease and the large number of animals made the studies very time consuming and very expensive. To counterbalance these disadvantages the disease had one great advantage, namely, the development of anatomical lesions in the form of tubercles. By means of these the selective penetration of such substances as dyes and stains could be easily and accurately determined. The belief had been strongly established in the mind of the author that the tubercles were relatively walled off from the circulation to such an extent as even to cause necrosis of their centres through lack of nutrition. He also felt that the general impression was that the tubercles were relatively impermeable to the usual materials and he was, therefore, surprised to find the ease with which they were actually penetrated by certain vital stains, such as isamine blue, which stained all the outer layers, and trypan red, which penetrated to the very interior of the tubercles.

Following this lead, efforts were made to determine which of a very large number of dyes were capable of specifically penetrating the tubercles in experimental animals. It was found that methylene blue, trypan blue, and many of the azo dyes were possessed of this power of penetration. Methylene blue not only penetrated the tubercles well, but was largely reduced in them. The problem then resolved itself into the building up of a large number of substances and combinations which had this penetrating power. Concretely, it was begun with trypan red, which entered tubercles well. The first steps were to form substances which retained this power of penetrating and which had the added power of destroying the tubercle bacilli or of inhibiting their growth sufficiently to aid the animal to recover from the infection. The dye was therefore combined with iodine, the phenols, etc., and these preparations were then tested on infected animals. Iodine was used on account of the long standing belief among clinicians that it had some special affinity for the tubercle bacilli. Phenol, guaiacol, etc., were known to be antiseptic toward the tubercle bacilli. This work had just got well under way when the war broke out and closed the market for the needed dye.

Search was therefore necessary for some other parent substance for modification. This was found in the commercial dye known as Niagara Blue II B, which had the advantage of being similar to trypan red chemically.

Parallel with this search for dyes with penetrating powers and capable of chemical modifications and additions, a series of studies was also undertaken to find substances which had specific antiseptic or inhibitory properties against tubercle bacilli. Several hundred substances were formed and tested in this respect, comparing their antiseptic properties against tubercle bacilli with those against staphylococci, pneumococci, and typhoid bacilli. The general results of these investigations showed that the typhoid bacillus was the most resistent of all the organisms to the anilin dyes; that the triphenyl methane group of dyes were least active on the tubercle bacilli; and that the group of azo dyes was the most highly specific against these organisms.

The conditions to be met were, then, first to find substances capable of chemical modification and having a high degree of penetration for tuberculous tissues; second, to find substances which had highly developed specific disinfectant or inhibitory actions toward the tubercle bacilli; and, finally, to combine these substances in such a way as to preserve both properties to the resulting combination. The first two problems were now fairly on the way to solution, but the third offered difficulties which had not yet been overcome. Thus it was found that generally efforts to increase the inhibitory action of a substance deprived it largely or entirely of its penetrating power in the living animal. Certain compounds of creosote, however, were produced which seemed to retain both properties in good measure. The testing of these compounds upon infected animals had now only been just begun and the results so far indicated that the use of the creosote compounds influenced the infected animals favorably in that they seemed to prolong their lives. But in this respect they were inferior to tuberculin and not superior to several other chemotherapeutic agents described by others.

The present status of the chemotherapy of tuberculosis might be stated to be hopeful for the future, although the experiments thus far carried out could not be described as successful, except as giving direction to the work yet to be done.

The Manual Treatment of Intussusception.—John Zahorsky (*Medical Fortnightly*, November, 1916) gives the following as the technic he uses: The infant is anesthetized and a pad is placed beneath the hips. After relaxation of the abdominal wall is obtained the tumor is grasped and a steady pressure is made upon it. It should be maintained for a minute or more and repeated several times. The knees or hips are firmly grasped and the abdomen shaken vigorously. When the tumor is centrally located an up and down motion may be used; when on the right side a lateral movement is more effective. In addition, stripping of the intestine, either from above downward or from below upward, may be practised. The taxis and shaking should be alternately repeated until the tumor has disappeared. The repeated jerks tend to throw the heavier mass away from the attached intestine.

Dietetics, Alimentation, and Metabolism

Food and Food Preparation, in Health and Disease

FOOD AND EFFICIENCY.

By Martha Tracy, M. D.,
Philadelphia,
Professor of Physiological Chemistry, Woman's Medical College, Pennsylvania.

IV.

DAILY REQUIREMENTS OF THE HUMAN BODY.

(*Continued from page 1056.*)

In regard to the reliability of the appetite in determining the amount of food needed, Sherman states:

If by following the appetite one becomes unduly stout, or is visited by digestive disturbances which are an obvious effort on the part of the body to free itself of a part of the food eaten; or, on the other hand, if one becomes unduly thin, or does not get sufficient fuel to support a full day's work, it is certain that some standard other than the appetite would be of decided advantage. But if from year to year the body keeps in good condition for its work and maintains a fairly constant weight, which bears such proportion to the height as to show that a desirable store of fat is being carried, it is reasonably certain that the amount of food eaten in the course of the year is substantially that which is suited to the degree of activity maintained; and, while it is possible that still further benefits might accrue from a different selection of food materials, it is not likely that any advantage could result from a material change in the amount (fuel value) of food consumed. Especially is it in the highest degree improbable that in such a case the same work could be done and the same weight maintained on food of much lower fuel value, however selected, prepared, or eaten.

It is of interest to note that a well ordered appetite may not only serve as an indication of the amounts of food needed over long periods and under different conditions of activity, but also when the conditions of life are fairly uniform may be highly efficient in determining a regular intake of calories from day to day. Thus a healthy young woman living on unrestricted diet with menus varied daily and eating simply according to appetite was found to take on five successive days 2,140, 2,025, 2,040, 2,250, 2,255 calories respectively.

That an appetite not as "well ordered" as that of the young woman referred to by Sherman cannot be depended upon as a guide to adequate food intake, is brought out in the following figures, the result of a dietary study by Dr. Caroline Croasdale in association with the writer. The figures are taken at random from over 200 observations of students attending the Philadelphia Normal School for Girls. All of the subjects are believed to be normal young women, who have passed the physical examination required for gymnasium work, and whose ages range from seventeen to twenty-one years. Each student made careful observation of her diet for several days, including all candy and other "between meal" indulgences, and calculated, under direction, from one of the reliable food value tables available, the caloric value of the food eaten.

The cases are arranged in four groups, as shown in the table. We have then added from the official records of the school a statement of the scholarship of each student, and also a sign which represents the vitality or efficiency, or margin of available energy of the individual. The student of so called "negative vitality" is quiet and listless, often anemic, and with no energy for anything beyond her school day of work, or even too little energy for this. The student of so called "positive vitality" is full of life, excellent at gymnastic work, leading in dances and entertainments, and in general with energy enough and to spare. Between the two is the neutral individual conspicuous in neither direction.

The table shows a summary of the results obtained and indicates the scholarship and vitality of the students in the different "food intake" groups stated in percentages.

Groups.	Scholarship.			Vitality.		
	Poor	Fair	Good	Negative	Neutral	Positive
26 students taking less than 1600 calories a day	57.6	30.7	11.5	57.7	11.5	30.7
38 students taking from 1600-2000 calories a day.....	23.6	42.1	34.2	63.2	7.8	28.9
24 students taking from 2000-2300 calories a day.....	8.3	54.1	37.5	50.0	0.0	50.0
37 students taking over 2300 calories a day.....	2.7	54.0	43.2	8.1	18.9	72.9

The students in the first group are evidently taking an amount of food very close to the minimum or basal metabolic requirement, and quite inadequate fo the maintenance of normal vigor at moderate activity. In over fifty per cent. of this group the vitality and the scholarship are below par. On the other hand, students taking an amount of food about equal to that suggested for adults under such conditions, show less than ten per cent. of poor vitality and scholarship, while "positive vitality" is noted in 72.9 per cent. of the group.

Such a study, though exceedingly superficial, is nevertheless extremely suggestive of the need of popular education as to the very definite and practical relation existing between the food requirement and intake.

V.

PROTEIN.

Having shown, then, that the average young adult requires a diet representing a total energy value of 2,500 calories, we have next to consider what part of this total food supply must be in the form of the essential tissue-building foodstuff, the nitrogen containing material, protein.

Here again both dietary and statistical studies (method 1 in the previous paper) and exact observations on intake and output of nitrogenous material (method 2 in the previous paper) have proved of value. Dietary studies show that the amount of protein eaten by men at different kinds of work does not vary as greatly as does the total fuel value of the food consumed. In Langworthy's table, cited above, it is seen that farmers, mechanics, business and professional men, students and laborers vary in protein intake only from 100 to 110 or 112 grams, while the total fuel value of the food varies from

2,511 to 3,480 calories. There is one conspicuous instance of an average for men at hard work of 177 grams of protein a day, and a few instances among the very poor of protein intake as low as sixty-nine and eighty-six grams. The professional men of Japan also showed a lower protein intake of eighty-seven grams a day, but at the same time with a lower total food intake of 2,190 calories.

On the whole, however, the protein intake as determined by choice is evidently little influenced by the amount of muscular work done, unless this is unusually great, and differs strikingly from the total need and choice in this respect.

Perfected methods for determining the amount of nitrogen in the food ingested, and in the urine and feces excreted, have been the means of reaching the conclusion that nitrogen balance experiments constitute the best method for determining the actual protein needs of the body. Under normal conditions the body protein must be maintained; the tissue cells must not be broken down faster than repair or reconstruction can take place; there must not be a greater excretion of nitrogenous material in the urine, feces, and sweat than is made good by ingestion of nitrogenous or protein material in the food. If the food protein in a day contains fifteen grams of nitrogen, and in the urine and feces for the same period there are twenty grams of nitrogen, the body has lost the amount of cell or protein tissue represented by that difference of five grams of nitrogen. The amount of nitrogen lost in the sweat under ordinary circumstances is so small as to warrant its neglect for ordinary clinical purposes.

If the nitrogen excreted is equal to the nitrogen of the food eaten, the subject is said to be in "nitrogen equilibrium," and a normal adult should remain in fairly constant nitrogen equilibrium. Studies which bear upon this subject have shown that a subject may alter his or her nutritive plane, and by ingesting a large but constant amount of protein may arrive at a nitrogen equilibrium on a high level; or by gradually reducing the amount of protein eaten, may again reach nitrogen equilibrium at a lower level.

The body protein can be maintained at a low level of nitrogen equilibrium only when adequate fuel food, carbohydrate and fat, is supplied. These fuel foods are therefore said to be "sparers" of protein. They enable the cells to conserve the protein for the more important tissue-building purposes, and none of it need, in the adequate presence of these sparers, be wasted for mere fuel.

Thus the physiologist, Siven, found that if his diet supplied a total of 2,484 calories (41.4 calories per kgm.), he could maintain nitrogen equilibrium on thirty-nine grams of protein a day, but if he decreased the protein to twenty-eight grams, there was loss of body nitrogen, or as it is termed, a minus or negative nitrogen balance. Such observations have therefore shown that the *minimum protein requirement* of the adult may be very much less than the amount of this material actually taken by the subjects of Langworthy's statistical table, who ingested somewhat more than 100 grams a day. Whether this *minimum* is necessarily the *physiological optimum* of protein requirement has been the subject of much controversy.

R. H. Chittenden,[1] of Yale University, as a result of an extended series of dietetic experiments on groups of subjects which included himself and his professional associates, soldiers on garrison duty at New Haven, and university athletes, reached the conclusion that sixty grams of protein a day is an adequate amount to maintain an average man at moderate activity on a sufficiently high nutritive plane as regards protein, providing carbohydrates and fats are supplied in sufficient amounts to make up a daily total of 2,500 to 2,800 calories. Other physiologists incline to the belief that Chittenden's allowance of sixty grams of protein a day is too low for the physiological optimum, and we are accustomed now to consider a protein ration of from seventy-five grams to ninety grams as more desirable. By thus allowing a supply of this tissue-building material somewhat in excess of the minimum, we are providing in the body a "factor of safety," as Meltzer puts it, a supply of material available for immediate use in reconstruction of cell protein, should any sudden emergency of cell destruction demand it. Persons, living in temperate climates, who, with adequate fuel supply from other sources, are taking daily over 100 grams of protein, are in all probability exceeding the physiological optimum.

Only under special physiological circumstances, such as pregnancy, or during the construction of tissue which takes place in the development of muscles during athletic training, or the building of tissue which occurs as body weight is restored after a long wasting disease—only under such conditions as these do we expect to find a plus nitrogen balance in the adult. Here there is a special call for building material and a larger part of the nitrogenous food eaten will be retained in the body. The excretion of nitrogen will be less than the intake.

In the child, on the contrary, there is always normally retention of nitrogen, a plus nitrogen balance, and a proportionately higher protein requirement to maintain the constant cell construction of proper growth. Nature's recognition of the tissue-building needs of the young animal is shown in the following interesting table:

Species of animal.	Days required to double weight.	Proportion of protein in the mother's milk.
Human	180	1.5 per cent.
Horse	60	2.0 per cent.
Cow	47	3.5 per cent.
Goat	22	3.7 per cent.
Sheep	15	4.9 per cent.
Pig	14	5.2 per cent.
Cat	9.5	7.0 per cent.
Dog	9.0	7.4 per cent.
Rabbit	6.0	14.4 per cent.

The human infant builds tissue at a rate which enables it to double its weight in 180 days, and for this purpose a food is provided containing 1.5 per cent. of protein. Fat and carbohydrate are also present as fuel. The table shows what a close relation exists between the rate of growth of the young animal and the concentration of the tissue-building material in its mother's milk. As the rapidity of growth is greater, as shown by the decreasing length

[1] *The Nutrition of Man.*

of time necessary for the young animal to double its weight, so the percentage of protein in the milk is increased. A safe working rule as to the amount of protein to be provided in the diet of the child or of the adult, is indicated by Sherman, who points out that in the infant's daily milk ration, as well as in the adequate food supply of the adult, one tenth of the total fuel value of the daily food is furnished in the form of this nitrogenous material.

It is important to remember, moreover, that the kind of protein is of considerable moment, for if certain of those aminoacids, referred to in an earlier paper as the building stones of the protein, are lacking, such a protein is inadequate for tissue construction, and must be supplemented in the dietary by others which will make good the lack.

There is another effect of the ingestion of protein food which deserves some consideration in relation to practical dietetics, the so called "specific dynamic action" of protein food. By this term we designate a certain stimulant effect upon the total body metabolism, a more rapid rate of combustion of the body fuel, and a greater generation of body heat, which follows the protein intake, so that more protein must be eaten than would theoretically be thought necessary to prevent loss of body substance. There is a similar specific dynamic effect following the ingestion of fats and carbohydrates, but it is much less marked than in the case of protein. Thus a larger amount of protein food may be eaten with advantage in cold weather, while the natural tendency to eat less meat in summer has this true physiological basis.

If seventy-five grams of protein are taken, then, as the adequate ration for the average adult, this will supply somewhat less than 300 of the total number of calories necessary for the day's fuel supply, the amount of this protein available for fuel being determined by the amount of tissue repair. Of our average apportionment of 2,500 calories a day, there will remain at least 2,200 calories to be supplied by carbohydrate and fat.

These substances, carbohydrates and fats, were referred to above as "sparers" of protein, but they are not of equal value in this respect. Fat is considerably less efficient as a saver of body protein than is carbohydrate, and while its actual fuel value when completely burned, is over twice as great, gram for gram, as is that of carbohydrate, it appears to burn less readily in the body, and cannot be used exclusively to complete the total fuel requirement. When such use of fat, to the complete or partial exclusion of carbohydrate from the diet is attempted, derangements of digestion are likely to occur, nitrogen equilibrium is not maintained, and a condition of acidosis results owing to formation and incomplete combustion of fatty acids from the superabundant fat. It is found that if one half or more of the fuel requirement is supplied in the form of carbohydrate, fat may advantageously be used to furnish the remainder. Taste can usually be trusted to accomplish this apportionment and will rarely if ever, under normal conditions, lead to excessive fat intake.

(*To be continued.*)

Food Contamination.—The dangers from food contamination by the transmission of animal parasites and infectious diseases, and the present inadequate means of supervision and inspection, are brought to our attention by a recent report of the Henry Phipps Institute, on the Storage, Handling, and Sale of Food in Philadelphia. That there is room for increased activity in this new and important field of public health work is clearly evident by the following from the report:

Need for investigation.—The causes of ill health, the prevalence of disease, and the comparatively high death rate in Philadelphia must, of course, be many. Prominent among them is the food question. No one doubts that the way in which food is handled and stored before it reaches us has an intimate relation to our physical well being. If we knew and realized the conditions under which food is stored, the way and by whom it is handled, and how much dust and dirt it has accumulated during its exposure in the stores and markets before it is purchased, we would, if merely from a sense of decency, be more insistent upon better protection and inspection of our foodstuffs. Philadelphia now has numerous laws and ordinances regulating the sale of certain foods. It also has a municipal division of food inspection for enforcing these regulations.

Much can be accomplished directly through the education of consumers. The shopkeeper must meet the demands of his customers. If they want the food that they buy covered and protected from the dust and dirt, they have merely to tell their dealer this, and if he finds that he must comply with these requests to keep their trade, it can be depended upon that he will do it. This is plainly illustrated by the contrast between stores in the residential and in the congested sections of the city. But even in the better districts, where there is a demand for more careful handling of foods, there is still room for improvement. Even in many of the best stores in the city there are numerous instances of the exposure to dust and flies of foods eaten without further preparation, washing, or cooking. In many cases vegetables and fruits are not raised eighteen inches, or even a foot, above the floor.

Field covered.—The Sociological Department of the Henry Phipps Institute, in 1915, under the direction of Mrs. Janice S. Reed Lit, made an investigation in Philadelphia of over 1,000 stores and about 200 pushcarts and street stands. Being without laboratory facilities, the exact condition of foods with reference to bacteria could not be determined, but stores and carts were examined and scored for various determining elements—sanitation, type, and number of workers, protection of food against contamination, grade of food handled, storage of food in the homes of the vendors, etc. A tabulation of these stores discloses startling and disgraceful conditions.

Selection of districts.—The districts chosen for study are considered as representative of various sections of the city. Race or nationality, degree of congestion, and previous health investigations played a considerable part in their selection. Jewish, colored, American, Italian, German, Polish, Irish, and mixed settlements were studied; congested and resi-

dential sections; and an effort was made to include in the study those portions of the city covered in the report of the child federation on infant mortality, Phipps Institute's study on tuberculosis, standards of living and housing, and the housing commission's report on congestion, in the hope that the data on food might throw some additional light on these other problems.

Variety of shops.—All kinds of shops were studied, groceries, bakeries, meat shops, fish markets, creameries, ice cream and confectionery stores, and produce establishments.

Street exposure of foods.—Practically all kinds of food are exposed in the stores—meat, fish, poultry, vegetables, fruit, dried fruits and vegetables, milk, confectionery, bread, etc. Many also are on the streets without protection, particularly fruit and vegetables, dried fruits, and poultry. These foods, even though they may be washed and well cooked before they are eaten, very often have the dirt so ground into them that it is practically impossible to wash them clean.

In the course of this study several authorities on the danger and extent of contamination of foods that require to be cooked were consulted. While there is a difference of opinion as to the extent of this danger, all agree on the need for protection.

Relation of Diet to Beriberi and Other Deficiency Diseases.—Edward B. Vedder (*Journal A. M. A.*, November 18, 1916) concedes that beriberi is due to the deficiency of certain substances, or a certain substance in the diet, and that it has been conclusively shown by a number of workers that a substance exists in the outer layers of rice which will prevent the development of the disease and will cure polyneuritis in birds when given in extremely small amounts. This substance has never been isolated in pure form, and its precise chemical constitution is not known owing to its decomposing during the process of extraction and purification. Recently substances have been prepared synthetically which are also capable of curing polyneuritis of birds, and these have been found to be characterized chiefly by a remarkable degree of dynamic isomerism which has a profound influence on their curative properties. Such substances belong to the hydroxypyridins, but it is probable that their properties do not depend upon their special chemical nature, but rather upon their isomeric properties. The vitamine isolated from yeast—adenin—also exhibits a marked property of forming isomers. The exact mode of action and role of the vitamines is not yet known and all explanations are mere hypotheses. Vedder suggests the hypothesis that the antineuritic substance which prevents beriberi acts as an essential building stone for the repair of the nervous tissue and that the disease is produced through deficiency in this substance by the occurrence of an exhaustion going on to the production of degenerative changes. This hypothesis is supported by the fact that very early in the course of the experimental production of polyneuritis in birds, long before the occurrence of symptoms, microscopical changes are demonstrable in the nervous tissues. Study of the several forms of deficiency diseases indicates that there is a number of different vitamines, the absence of each of which is responsible for a definite form of disease. It is well known that the dietetic deficiency which produces beriberi does not lead to scurvy, and vice versa. It is, further, probable that pellagra is a deficiency disease, for those who are its victims live on diets known to produce scurvy and beriberi. They are probably, however, protected from these diseases by the introduction of other articles of food which still leave them susceptible to pellagra. Our knowledge of the deficiency diseases, though meagre, indicates the necessity of certain dietary rules to prevent their occurrence. Thus, where bread is a staple article of diet, it should be made of whole wheat flour; brown, undermilled rice should be used where this article is a staple in the diet; fresh beans, peas, and legumes should be given at least once weekly; fresh fruits and vegetables should be used once or twice weekly; barley, known to prevent beriberi, should be used in all soups; yellow, or water ground corn meal should be used; white potatoes and fresh meat should be given daily if possible, and in any case at least once weekly; canned goods should not be used too exclusively.

Boiled Milk in Infant Feeding.—Joseph Brennemann (*Journal A. M. A.*, Nov. 11, 1916), after a careful consideration of the facts, combined with an extensive experience of the use of both raw and boiled milk, has been led to give decided preference to the latter for both normal and sick infants on artificial feeding. He emphasizes the facts that, at best, raw cow's milk is not a natural food for human infants; it tends to coagulate in large, firm masses which are digested only with considerable difficulty and very imperfectly; there is little evidence to support the idea that it contains vitamines or kindred substances which are essential to human infants; it is always contaminated with more or less harmful bacteria; and it tends to produce diarrhea. As to boiled milk, however, he cites the following facts: There is little or no evidence to show that it is any more abnormal a food than when raw; the evidence that it tends to cause scurvy is not convincing; such tendency, if present, can be overcome easily by the use of orange juice; boiling sterilizes the milk; it makes it coagulate in very small, soft masses which are easily digested; and boiled milk tends to reduce the number of stools due to its more perfect digestion. Indigestion of casein does not occur with boiled milk, and when it has occurred from the use of raw milk it may be checked at once by the use of the boiled product. The experience of European pediatrists has long proved the value and harmlessness of boiled milk. The author's own experience has shown practically that much larger amounts of milk and much more concentrated feedings can be given safely when boiled milk is used. A healthy infant of nearly any age can begin with half boiled milk and half diluent, and undiluted milk can be given much earlier when boiled. Boiling is an easy and efficient means of modifying the casein to render it more digestible and entirely eliminates the problem of bacterial contamination. Feeding is made safer, easier, and more certain of success in both normal and sick infants. Boiling should be for a period of about five minutes and should be done in the home before the preparation of the feeding.

Milk and Communicable Diseases.—Linsly R. Williams (*Medical Record,* October 28, 1916) remarks that the chief objection to pasteurization is the change from long continued use of raw milk, and that the health insurance given by pasteurization in preventing epidemics of milk borne diseases is more important than the cost of the process. Changes in the taste of the milk occur only when too high a temperature is used. The slight danger of scurvy may be easily overcome by the administration of orange juice to children from the sixth month on. There is no foundation in fact for the statement that the amount of cream is diminished; truly, the cream line may be lessened, but the total amount of fat content remains the same.

Care of Digestion.—Max Einhorn (*Medical Record,* November 18, 1916) lays down the rule that in health the dietary should comprise a great variety of food, difficult of digestion as well as digestible, in order to give the digestive apparatus something to do in order to prevent deterioration. Meat should not be taken more than twice daily, and about four ounces suffice for an adult with vegetables, bread and butter, fruits, and salads. Water should be taken at each meal and between meals if there is thirst. Exercise in the fresh air such as walking, riding, and rowing, are of value. In short, care of digestion includes the simple life, with balanced work, recreation, regularity of meals, frugality, diversity of foods, abundance of water, and care of the bowels.

Diet in the Nephroses.—Fritz Munk (*Medizinische Klinik,* October 8, 1916) asks us to bear in mind in attempting to feed a patient with one of the nephroses, that we are dealing with a chronic condition and that dietetic regulation will have to be continued for long periods. Every effort should be made to make the diet as varied as possible, and palatable as well, so that the nutrition of the patient shall not suffer from distaste for food. During the stage of marked edema the patient eats so little that we should not further assault his appetite by attempting a saltfree diet. Instead, we should be content with a reduction of the salt to two or three grams daily, which will usually accomplish as much as the total removal of salt. The salt should then be very slowly increased as the patient recovers, about six grams daily being the highest amount desirable to reach. It is better to reduce the salt slightly and keep the amount constant than to resort to sudden fluctuations in the amount. The total protein intake should be reduced, but it is erroneous to allow no meats. On the contrary, it is better to employ small amounts of meat protein in an adequate mixed diet than to attempt to meet the patient's caloric needs with the milk diet so commonly prescribed. The diet should be free from all but traces of condiments, but enough of these should be used to appeal to the patient's appetite in order to encourage him to continue with the diet. It is not necessary to restrict the intake of carbohydrate. The total amount of fluid taken daily should be limited and should be reduced to 500 mils, if possible, though it will often be necessary to allow as much as one and a half litre. This can be made up of tea, coffee with milk, fruit juice drinks, thin gruels, and alkaline waters containing but little carbon dioxide. The control of the diet is best accomplished on the basis of the caloric needs of the patient and the caloric values of the foods prescribed. As much as half of the protein requirement may be supplied in the form of meat, fresh water fish, and sardines in oil. Eggs should be restricted to a maximum of three a day and should always be cooked. Artificial food preparations are not to be recommended.

Value of Thick Gruels in the Diet of Infants.—Erich Klose and Heinrich Bratke (*Medizinische Klinik,* September 24, 1916) prefer, like most pediatrists, the thick gruels made from cereals by prolonged boiling and straining, to the ordinary cereal soups made with brief cooking. The authors have made a series of observations upon these two forms of cereal preparations to determine the differences, and the reason for the preference of the one over the other. They found that there was relatively little difference in either the protein or the carbohydrate content of the two preparations—at least far too little to be the reason for preferring the long cooked gruel. After the elimination of all other possible differences they were forced to the conclusion that the gruel which had been made with long cooking —three quarters of an hour or over—possessed the one advantage of having had its contained starches so altered in form as to be much more readily digested and more completely assimilated by infants.

Gastrointestinal Acidosis in Infants.—Henry Dwight Chapin and Marshall Carleton Pease (*Journal A. M. A.,* November 4, 1916) conclude that this form of acidosis in infants is closely related to the feeding of whole milk or some form of whole milk formula, and that it is the protein of the milk which is primarily at fault. The probability is that the condition results from some partial breaking down of the protein through bacterial activity, with the production of toxic split products. It was noted that this form of acidosis was very quickly fatal, but that the children usually improved rapidly if they lived long enough for a cathartic to act. As a result of these observations starvation treatment was tried with excellent success. This starvation was complete, except for the administration of water and a solution of sodium bicarbonate. The sodium bicarbonate was only a temporary measure, and the starvation seemed the more important. This treatment was combined with the administration of a cathartic to clean out the entire intestine, and it was found that this could not be replaced by gastric and colonic lavage. The alkali was given till the urine was rendered alkaline or the blood showed a normal reaction. Every possible mode of administration was employed to introduce enough bicarbonate into the circulation to combat the urgent symptoms. After this immediate treatment the infant's diet was readjusted so as to eliminate milk entirely for a considerable time. Thick gruels, cooked for many hours, were given with sugar to meet the caloric needs of the child, and animal proteins were introduced only after some time on such a restricted diet and then very slowly and with great care.

NEW YORK, SATURDAY, DECEMBER 9, 1916.

THE NARCOTIC DRUG EVIL.

At the last session of the legislature of the State of New York, a joint committee was appointed to investigate and report upon the narcotic drug evil in order to draft legislation to prevent its growth. This committee, under the chairmanship of Senator Henry M. Whitney, of Mechanicsville, himself a practising pharmacist, held public hearings during the past week at City Hall, New York. Several physicians and pharmacists appeared and a number of men who have been interested in the movement to suppress the illegal traffic. Among those who spoke was Burdette G. Lewis, Commissioner of Correction of the City of New York, who said that from the standpoint of his department, the treatment of the drug addict was a most serious question. Mr. Lewis submitted a mass of statistics regarding the prevalence of drug addiction among the correctional population, and said that of those who came under the care of his department the drug addicts were the most troublesome. He made a special plea for an indeterminate sentence for addicts sent to the department, since experience had demonstrated that a period of from four months to a year, or even more, was required for the cure and rehabilitation of a confirmed drug user, therefore no specific sentence would bring about the results desired. He particularly deplored the hurried treatment for a few days, followed by the discharge of the patient in such a state that recurrence of the habit was almost inevitable.

An earnest plea was made by one physician to the legislators on behalf of the sick and suffering whose pain could be alleviated only by the proper use of narcotic drugs, and on behalf of the medical profession whose duty it was to alleviate that pain. It was argued that it was not by the restriction and hampering of the physician and the druggist in the legitimate discharge of their duties to the sick, that relief from the drug evil was to be found; this was a police matter and not a board of health matter. Dr. Jackson R. C. Campbell, physician at the Harlem prison, said that the physicians and pharmacists were not at all involved in the growth of the narcotic drug evil, that few of the young men suffering from the drug habit had ever been seen by a physician, and that it was absurd to bring the doctor and the druggist into the matter at all. The illegitimate users of the drug had sources of supply entirely outside of the medical profession and the pharmacists. He invited the members of the committee to inspect the Harlem prison and see with their own eyes the condition of the habitués who were confined there. He knew whence the supply of narcotic drugs came, but his life would not be worth a day's purchase if he should divulge this knowledge.

The gratifying assertion that the medical profession and the pharmacists are not involved to any appreciable extent in the illegitimate traffic in narcotic drugs, was further confirmed by the statistics furnished by the District Attorney of the County of New York, who said that less than ten per cent. of the offenders against the narcotic drug laws were either doctors or druggists.

It seems then an outrage to impose still further restrictions on the legitimate practice of medicine and pharmacy in the handling of narcotic drugs. The remedy should be applied to the ninety per cent. of offenders outside these callings. In spite of these statistics, however, we find Judge Collins, who has been active in a campaign to suppress the narcotic drug evil, coming back to the proposal made two years ago, and advising the use of official prescription blanks, with an additional blank to be used when narcotic drugs are prescribed for addicts. The application of even a modicum of common sense would show the absurdity of attempting to correct this evil by dealing only with the very small proportion which can be laid at the

doors of medicine and pharmacy. We know now that it is a social and not a medical problem, and it is a gross injustice to the medical profession and to the patients who have a legitimate need for narcotic drugs to impose further restrictions upon the doctor. Here is an opportunity for the New York State Medical Society to aid in protecting the profession from a most unjust law by preventing the imposition of additional restrictions on the practice of medicine as is now proposed. It is the business of the legislators to ascertain the source of supply and the channels of distribution of the drug in the underworld, and to close them. This can be done without further hampering the practice of medicine.

MINERAL OIL IN CONSTIPATION.

To judge by the number of manufacturers that have put some preparation of mineral oil upon the market, the prescription of it must have grown by leaps and bounds since it was first put forward as a sort of substitute for Sir Arbuthnot Lane's kink operation. Most of the "literature" is still of a proprietary nature, and it is natural, therefore, that we should read with interest the contribution to *Paris médical* for June 24, 1916, of Le Tanneur, on what he calls practical points in the use of mineral oil in constipation. Olive oil, he observes, has long been a favorite laxative in Provence and elsewhere, but only that portion of each dose that is not saponified by the liver and pancreas acts in a laxative manner, consequently there is fatigue at the expense of digestion on the part of these glands whenever it is exhibited. With mineral oil, on the other hand, there is no saponification and no reflex of any kind is excited; the fecal mass is simply lubricated and its passage greatly facilitated. Moreover, the interior of the intestine is covered with a thin protective film, and any tiny excoriations caused by rough particles of food are healed. Since we are concerned with a purely mechanical action, habituation to the oil on the part of the patient is impossible.

An interesting fact elicited by Le Tanneur is that at autopsy of several subjects who were under mineral oil treatment at the time of death, the appendix was found to be literally filled with oil; we must remember that this means absolute sterility of the appendix. Le Tanneur insists on the importance of prescribing a pure and specially prepared oil, one worthy of the dignity of inaugurating a perfectly new and unequalled form of treatment for an historically obstinate condition.

We prescribe two tablespoonfuls of the mineral oil daily, before breakfast, fasting, or after dinner, as the patient prefers. The first stool induced by the oil will appear in about forty-eight hours, and as there is, so to speak, no lubrication ahead of it, there may be some difficulty and straining in its passage; this should be forestalled by an enema. The bowels soon become regular, but the oil should be taken every day for at least a fortnight. The patient will then be astonished to note that the bowels continue to move daily, although the oil has been withdrawn. He should have the fact impressed upon him that he is not taking an ordinary cathartic, but a new treatment for constipation, which will cure if persisted in, and he is therefore not to be discouraged if the effects at first are not as great as he had expected. Children may have a sweetened preparation of the oil, but this is not usually necessary, as a good oil has not a fatty appearance, nor even a greasy taste. Le Tanneur gives credit to Gaudier, of Lille, and Pauchet, of Amiens, for their speedy appreciation of Sir Arbuthnot Lane's discovery and their immediate practical application of it.

FUNCTIONAL MEDICINE.

The present tendencies in medicine are largely based upon functional studies and experiments. The prevention of disease and the study of function are preeminent characteristics of modern medicine. The control of infectious diseases made possible by the advances in bacteriology has materially affected the incidence of such diseases. In their place we have an ever increasing number of functional derangements of every sort. For the diagnosis and treatment of these latter conditions a knowledge of what constitutes normal function is absolutely essential. In connection herewith the biological sciences, especially physiology, biochemistry, and psychology take on new value, and offer great opportunities for future development.

In order that these new discoveries may be of the greatest usefulness, however, there is need for a better understanding of fundamental physiological principles, and a much wider appreciation of functional possibilities. To these must be added the ability to correlate new findings, and to detect departures from the normal in their early stages. It is only from such studies as these that we may hope to acquire that breadth and keenness of vision so essential today to offset the narrowness and concentration of specialism. The old proverb of not being able to see the wood for the trees returns to mind with added vigor and warning.

Another advantage to be hoped for from these new physiological developments, is a return to simple remedies and the prescribing of healthful rules of life. The pride of many patients may suffer,

and some of our methods of cure may have to be radically changed, but our diagnoses will be more fundamental and our therapeutics more vital.

THE ARTFUL ANOPHELINÆ.

Most of us associate the malarial mosquito with cesspools, marshes, swamps, etc., and are apt to forget that this wily insect may make use of very unexpected places to rear her offspring. This is brought to mind by a recent issue of the *Public Health Reports* (also New York Medical Journal, December 2d, page 1110), which contains a communication from Acting Assistant Surgeon W. J. Stewart, on duty at La Guaira, Venezuela. The American consul at this place had complained of the unusual prevalence of mosquitoes in his offices. Accordingly the immediate vicinity was searched for breeding spots, these being sought for in the usual places, such as rain gutters, sewers, etc. But no larvæ were found. By chance, however, attention was called to the water cooler in use in the office. This was of the inverted type where an ice chamber surrounds a porcelain compartment through which the water passes. Here it was that the mosquitoes were finally found, breeding in the ice cold water! The installation of thorough daily attention to the ice chamber was followed by the complete disappearance of the mosquitoes.

This utilization by the mosquito of a medium which we should think offhand would be incapable of supporting such forms of life should be a warning to us not to neglect any collection of standing water when we are on the search for the breeding places of the anophelinæ. Water coolers, water pitchers, flower vases, in fact any place where water is allowed to stand for a day or more, may become a focus of trouble, and we should not feel contented until we have investigated all such places.

PROTECTIVE OR DESTRUCTIVE?

One of the important problems before the physician day after day, is to determine whether a phenomenon of disease indicates that the body is being injured or protected thereby. It used to be supposed that a rise of temperature was always injurious, and in the days when that theory held sway every means was used to bring the temperature back to normal. At present the idea is advanced, if not substantiated, that fever is indicative of the attempt of the body to destroy or inhibit, by high temperature, the growth of bacteria, and, such being the case, the hyperpyrexia should be let alone unless it becomes too great. We know, however, that the body temperature may become elevated without bacterial invasion, so that, if sometimes a blessing, more or less in disguise, high temperature as in heat stroke may also be a curse. The rapid heart which accompanies infection would seem always to be a part of the general protective reaction, yet there are still those who, in the presence of such a symptom, invariably resort to aconite or veratrum. We know that diarrhea is a protective phenomenon, but is it always so? We know that coughing is a protective mechanism and needs usually to be encouraged, but again where there is nothing to clean from the air passages it is far from useful, and ought to be checked. Sneezing is undoubtedly protective, but not for the victim of hay fever. Because the measuring of blood pressure is a new procedure, a pressure above the usual has seemed a sign of menace, when, in many instances, it is merely a sign of compensation for incurable faults, and the patient is worse off if attempts are made to decrease the pressure. Again, thirst was once considered an abnormal condition in the feverish patient, and he was further tortured and injured by restriction in the amount of water he should consume.

Practically all symptomatic treatment—and most medicinal treatment is symptomatic—depends for its value on this determination of whether a function is increased or decreased to the advantage of the patient, and hence, whether we are to stimulate or check the activity of an organ. It does not do to follow fixed rules in the matter, for, like the firm believer in the importance of coloration in animals, we may be puzzled by finding a medical condition analogous to the coexistence in the same surroundings of both a black and a white animal. While strict laws cannot be laid down to cover all cases of overfunction or underfunction, it would be a great help if we knew more definitely about some of these phenomena. It is not yet established that fever is always, or ever a protective measure in infections; loss of appetite is by no means always understood, and we are much at sea whether the craving of the sick for certain foods is to be yielded to or denied. It would seem that much useful experimenting might be carried out along these lines for the establishment of better rules of guidance in such important matters.

NOMENCLATURE: ENTERIC AND TYPHOID.

Dr. Aldo Castellani writes from Rome to the *Lancet* for November 25th apropos of a recent suggestion that the term, enteric, should be used to cover the three infections, typhoid, paratyphoid A, and paratyphoid B, while the term, typhoid, was to be restricted to cases caused by the Eberth-Gaffky bacillus. Doctor Castellani points out that this distinction was made in 1913 in the second edition of the *Manual of Tropical Medicine*, written by him in collaboration with Doctor Chalmers.

AN UNUSUAL CAUSE OF ABORTION.

Joseph E. G. Calverley, of Folkestone, communicates to the *Lancet* for November 18, 1916, a case where the Fallopian tube became engaged in the sac of a femoral hernia and so caused abortion. The patient, aged thirty-six years, who was pregnant four months and had come to Folkestone for a holiday, was seized with acute abdominal pain in the left lower abdomen while at an entertainment. The following day (August 18th) the pain continued and was referred to the left femoral region, where a swelling the size of a chestnut was detected. This swelling was painful to the touch. The same day a blood stained vaginal discharge appeared, which was the starting of a miscarriage. For a few days there was no evident change in the swelling in the left femoral region, but on August 24th there was marked increase both in the severity of the pain and also in size, which called for surgical interference. The operation revealed a femoral sac containing a deeply congested, almost black Fallopian tube and its fimbriated extremity. This was excised. The following year the patient gave birth to a living child.

THE INDEX CATALOGUE.

One of the pleasures of editing a medical journal lies in the periodical welcoming of a new volume of the *Index Catalogue* of the library of the Surgeon General's office, United States Army. We have just received Volume XXI of the second series, authors and subjects, taking in titles from Waterworth to Zysman, and are again glad to note the scholarship, the care, the patience, and accuracy displayed in getting out the monumental production. Indispensable to professional medical writers, the catalogue should be welcome to all physicians of literary tastes, particularly at the remarkably low price, two dollars a volume. Lieutenant Colonel C. C. McCulloch, Jr., librarian of the surgeon general's office, gives a full list of the generous donors during the past year to the army's collection of books.

Obituary

PHILIP MILLS JONES, M. D.,

of San Francisco.

Dr. Philip Mills Jones died at his residence in San Francisco on November 27th. He was born in Brooklyn-New York, on January 17, 1870, and was consequently in his forty-seventh year. He was educated at the Polytechnic Institute of Brooklyn until 1886, after which he spent a year at New York University. He graduated as M. D. from Long Island College Hospital in 1891, and practised medicine in Brooklyn until 1900, when he moved to San Francisco to take up archeological work for the University of California. In 1902 he became editor of the *California State Journal of Medicine,* a position he retained until his death. Doctor Jones was married only last year. He was a trustee of the American Medical Association, and had been vice-president of the American Academy of Medicine and secretary of the Medical Society of the State of California.

News Items

Drug Habitués in New York State.—At a public hearing held by the legislative committee which is investigating the drug habit evil in this State, the statement was made that there were 200,000 persons in New York State addicted to drugs.

Harvey Society Lectures.—The fourth lecture in the course will be given on Saturday evening, December 16th, by Professor Henry H. Donaldson, of the Wistar Institute of Anatomy and Biology, Philadelphia, his subject being Growth Changes in the Mammalian Nervous System. The fifth lecture will be given on January 13th.

Meetings of Medical Societies to Be Held in Philadelphia during the Coming Week.—Tuesday, December 12th, Pediatric Society; Wednesday, December 13th, County Medical Society; Thursday, December 14th, Polyclinic Ophthalmic Society, Pathological Society; Friday, December 15th, Jefferson Hospital Clinical Society.

State Hospital Changes Name.—The name of the Long Island State Hospital for the Insane has been changed to Brooklyn State Hospital. The change in name was made to avoid confusion with the Long Island College Hospital. These two institutions are in two widely different parts of the city and there should be no further trouble over the misdirection of letters, packages, or patients.

Long Island College Hospital.—At a conclave of the student body and the faculty of the Long Island College Hospital, Brooklyn, held on Monday, December 4th, the graduating class presented to the college a photographic portrait of the late Dr. Joseph H. Raymond, formerly secretary of the faculty and professor of hygiene in the college. Dr. John D. Rushmore, dean of the faculty, made the address of acceptance.

Surgeons Wanted for War Hospitals.—The French War Relief Association has received an urgent call for two surgeons to take full charge of the operating wards of two military hospitals in France. The association will defray the cost of transportation to and from the hospitals, and the immediate needs of the surgeons will be met by the institutions. Applicants should address Dr. Joseph Leidy, 1319 Locust Street, Philadelphia.

The Mütter Lecture.—The 1916 Mütter Lecture on Surgical Pathology of the College of Physicians of Philadelphia will be delivered on Friday evening, December 15th, by Dr. Nelson M. Percy, of Chicago, professor of clinical surgery in the Medical School of the University of Illinois. His subject will be Pernicious Anemia with Special Reference to Its Surgical Management. All physicians are cordially invited to be present.

The Academy of Medicine to Organize a New Section.—Fellows of the New York Academy of Medicine are planning to organize a Section in Historical Medicine. The organization of new sections is provided for in Article VI of the constitution, which reads as follows:

> The academy may be divided into as many sections for the transaction of scientific business as may be recommended by the Council, after a request in writing by twenty or more Fellows, and approved by a three fourths vote of the Fellows present and voting at a stated meeting of the academy.

American Aid for Belgian Physicians.—Dr. F. F. Simpson, of Pittsburgh, treasurer of the Committee of American Physicians for the Aid of the Belgian Profession, reports that during the quarter ending November 30, 1916, two contributions to the fund were received, one of $10 from Dr. Edward E. Mayer, of Pittsburgh, and one of $1.40 from Dr. W. C. Cahall, of Philadelphia. This is Doctor Cahall's third contribution. The total amount received by the committee is $7,958.26; total disbursements amount to $7,310.04, leaving a balance on hand of $648.22.

Ohio Valley Medical Association.—At the eighteenth annual meeting of this association, held in Evansville, Ind., Wednesday and Thursday, November 21st and 22d, Dr. William Shimer, of Indianapolis, was elected president, and other officers were elected as follows: First vice-president, Dr. J. Rawson Pennington, of Chicago; second vice-president, Dr. W. F. Boggess, of Louisville; third vice-president, Dr. M. L. Heidingsfeld, of Cincinnati; secretary and treasurer, Dr. Benjamin L. W. Floyd, of Evansville, reelected.

New Officers of Tri-State Medical Association.—At the thirty-second annual meeting of the Tri-State Medical Association of Mississippi, Arkansas, and Tennessee, held in Memphis recently, Dr. J. W. Gray, of Clarksdale, Miss., was elected president, and other officers were elected as follows: Dr. Rogers Hays, of Carrollton, vice-president for Mississippi; Dr. R. W. Griffin, of Tiptonville, vice-president for Tennessee; Dr. Floyd Webb, of Turrell, vice-president for Arkansas; Dr. J. L. Andrews, of Memphis, reelected secretary; Dr. J. A. Vaughan, of Memphis, reelected treasurer. Memphis is the permanent meeting place of the association.

The Sale of Red Cross Christmas Seals in New York.—There are three agencies for the sale of these seals in New York, namely, the State Charities Aid Association, which manages the sale throughout the State, including Staten Island; the New York Committee, which manages the sale for Manhattan and the Bronx, and the Brooklyn Tuberculosis Committee, which manages the sale of seals in Kings and Queens. Attention is called to the fact that the Brooklyn committee is entirely separate from the committee which manages the sale of seals in Manhattan, and only those seals which are sold in Brooklyn are credited to that borough. For the past two years Brooklyn has sold more seals in the United States than any city.

Columbia University.—Dr. E. E. Southard, professor of neuropathology in the Harvard Medical School and director of the Psychopathic Hospital, Boston, has been appointed nonresident lecturer in psychology in the College of Physicians and Surgeons. Dr. Alexander Lambert has been appointed professor of clinical medicine, and the following named doctors have been appointed instructors in medicine: Dr. Lewis Bibb, Dr. Edward L. Pratt, Dr. Edward C. Lyon, Dr. Charles E. Carr, and Dr. William Wheeler Cox.

Announcement is made of a gift of $5,000 from Mr. George L. Rives toward the medical school removal and rebuilding fund, and a gift of $750 from an anonymous donor toward salaries in the medical school.

Personal.—Dr. Barton K. Thomas, of Philadelphia, has been appointed an instructor in clinical medicine at the Jefferson Medical College.

Dr. William Hamilton Jefferys until three years ago a medical missionary in China, has been appointed superintendent of the P. E. City Mission of Philadelphia. Doctor Jefferys has taken an active part in the movement for occidental medical education in China.

Dr. Abraham Jablons, of New York, has been commissioned lieutenant surgeon of the White Cross Hospital and Relief Association, Incorporated, of Brooklyn, New York.

Dr. James J. Philips, of the University of North Carolina, has formed official connection with the medical department of the White Sulphur Springs, W. Va., bath establishment, and entered upon his duties on November 30th.

Dr. Ernest L. Walker has been appointed lecturer in tropical medicine at Harvard Medical School.

Dr. Hugh Cabot, of Boston, who was surgeon in chief of the Harvard unit at General Hospital No. 22, British Expeditionary Force in France, from June 29th to September 9th, and was succeeded by Dr. Daniel F. Jones, will soon return to France to act as head of the unit until the end of the war.

Dr. Joseph M. Thüringer, of Harvard Medical School, has been appointed head of the department of anatomy of the School of Medicine of the University of Alabama. Dr. Claude W. Mitchell, of Chicago, has been made head of the department of physiology and pharmacology.

Section in Pediatrics of the Academy of Medicine.—The following program has been arranged for the next meeting of the Section in Pediatrics of the New York Academy of Medicine, which will be held on Friday evening, December 15th: Report of a case of tuberculosis from ritual circumcision, by Dr. Mark S. Reuben; The History of Pediatrics in New York City, by Dr. Abraham Jacobi; The Problem of the Cardiac Child, by Dr. L. Emmett Holt; The Open Air Treatment of the Cardiac Child, by Dr. Herbert B. Wilcox; The Elucidation of Some Arrhythmias of the Heart in Children by Means of the Electrocardiograph, by Dr. Robert H. Halsey. The discussion will be opened by Dr. Walter B. James, president of the academy.

Bronx County Medical Society.—The annual meeting of this society will be held at Ebling's Casino, St. Ann's Avenue and 156th Street, the Bronx, Wednesday evening, December 20th, at 8:30 o'clock. The program includes a paper by Dr. William P. Healy on Incontinence of the Urinary Bladder in Women and a paper by Dr. John H. Telfair on Indications for Cæsarean Operation. The election of officers will take place at the close of the scientific session. At the November meeting of the society the following nominations were made: For president, Dr. J. Lewis Amster and Dr. Herman T. Radin; for first vice-president, Dr. John Decker and Dr. William M. Dunning; for second vice-president, Dr. Maximilian Zigler and Dr. Maurice Silverman; for treasurer, Dr. Philip Eichler; for secretary, Dr. Isadore J. Landaman and Dr. Vincent S. Hayward.

A Scotch Hospital Established in Brooklyn.—The Caledonian Hospital, situated at 53 Woodruff Avenue, corner St. Paul's Place, Brooklyn, was opened recently. It is the first Scotch hospital in America and is nonsectarian. Dr. William J. Cruikshank is president of the medical and surgical staff and Dr. William H. Rankin is secretary. The following are the heads of the different departments: Medicine, Dr. William J. Cruikshank; surgery, Dr. William H. Rankin; obstetrics and gynecology, Dr. Albert M. Judd, with Dr. Victor Robertson associate; genitourinary surgery, Dr. Robert Burns Anderson, with Dr. Burton Harris associate; neurology, Dr. Carroll L. Nichols; pediatrics, Dr. Walter D. Ludlum; ophthalmology, Dr. P. Chalmers Jameson; laryngology, Dr. Robert L. Moorhead; otology, Dr. Nathan T. Beers; röntgenology, Dr. William H. Wallace; anesthesia, Dr. Richard Mills.

New York Diagnostic Society.—Announcement is made of the organization and incorporation of this society, with the following officers to serve for the first year: President, Dr. Joseph Mandelbaum; first vice-president, Dr. De Witt Stetten; second vice-president, Dr. Otto Hensel; treasurer, Dr. Julius Auerbach; secretary, Dr. Monroe Künstler. The object of the society is to foster the establishment of institutes for group diagnosis, and it was organized through a suggestion, which Dr. Charles H. Mayo, of Rochester, Minn., recently made in an address before the Catholic Hospital Society of Milwaukee, in which he emphatically expressed the opinion that the one great need in hospital advancement was an institution devoted exclusively to diagnosis. Doctor Mandelbaum made an extended stay at the Mayo clinic last year, where he undertook an intensive study of their system and also of other important American clinics with the same object in view. Over three hundred practitioners of medicine in New York city and vicinity have already enrolled themselves as associate members of the society.

On Tuesday evening, December 5th, Doctor Mandelbaum was honored with a dinner by the society and influential lay citizens who are deeply interested in this project. Many physicians and citizens were speakers, among whom may be mentioned Dr. Robert T. Morris, of New York; Dr. Judson Daland, of Philadelphia; Dr. Ira S. Wile, of New York; Mr. Cleveland Moffett, the author; and the Hon. George Gordon Battle. The society is planning to establish in New York the first diagnostic hospital in this country, and nearly $100,000, about half the amount needed for buildings and site, has already been pledged.

Modern Treatment and Preventive Medicine

A Compendium of Therapeutics and Prophylaxis, Original and Adapted

THE THERAPEUTICS OF A PHARMACOLOGIST.

By A. D. Bush, M. D.,

Professor of Pharmacology and Therapeutics, University of Southern California.

Forty-seventh Communication.

NEPHRITIS.

Concerning the several means and methods used in cases of nephritis, both acute and chronic, only a few words may be said explanatory of the pharmacodynamics involved. Whenever the eliminative function of Bowman's capsule is interfered with through the pressure of inflammation products there is retention in the blood stream of excess liquid approaching in quantity the amount of the diminution of the urine. Failing of excretion this liquid infiltrates the cellular tissues of the body as the osmotic pressure rises. There is considerable reason for believing that threatening eclampsia is due more to this accumulating liquid and pressure, than to the urea that may be retained: consequently anything that relieves this pressure, like free diaphoresis, alleviates the symptoms and wards off the danger. In these cases, diaphoresis is best induced by wrapping the patient in woolens, applying heat externally, and giving hot drinks, or enemas. Relief from the urgent symptoms is usually rapid, though extremely minute amounts of urinary solids are found in the perspiration thus induced. The principal drug available for the promotion of sweating is pilocarpine, which acts by stimulating the sweat glands at the nerve terminations: but this drug, because of the severity of its action on other glandular structures, is not recommended except in grave emergencies.

Diuretic drugs in acute nephritis are of little use, since the mechanism upon which the drug is supposed to act is rendered nearly functionless by the pressure from intercellular exudation products. In the parenchymatous type of chronic nephritis, there is a similar interference with function becoming increasingly marked in the later stages. If any diuretic is indicated, caffeine citrate is the most efficient to use judging from its effects on the normal kidneys; but there is ever present a doubt as to whether the epithelial irritation produced will ultimately prove beneficial or otherwise; especially since not a few of these chronic cases have their etiology in long continued, local irritations similar to that produced by caffeine. Probably in some few selected instances, however, caffeine will prove temporarily helpful: such cases are the comparatively rare ones manifesting a low arterial tension.

Where the blood pressure is high, and arterial elasticity is low a different course must be followed. Here the immediate danger is not from the "uremia" of heightened osmotic tension, but from an impending rupture of sclerosed arteries due to the high blood pressure. In these circumstances the best available drug is nitroglycerin, which has a detonizing action on arterial musculature thereby tending to a lowering of blood pressure through peripheral dilatation, especially in the splanchnic area, but since a tolerance for the drug is gradually acquired, the initial dose of 1/100 grain must be steadily increased to maintain the desired effect, the dose in later stages rising as high as one twentieth grain for eliciting the same fall in blood pressure as by the initial dose.

An interesting experiment by Dr. Crile involves the hypothesis that high blood pressure in chronic Bright's disease is due to augmented afferent impulses to the suprarenal glands. In a case reported, severing of these nerves was at once followed by a remarkable fall in blood pressure. Of course this operation probably has small effect on the progress of the disease, but it may easily prolong the life of the patient by protecting him from an apoplectic attack.

Medicines can have little curative influence in chronic Bright's disease, inasmuch as the main difficulty is the increasing fibrous change, and drugs have apparently no effect in reducing this condition.

Treatment of the Vomiting of Pregnancy by the Duodenal Tube.—B. H. Gray (*Virginia Medical Semi-Monthly*, October 27, 1916) asserts that, while in mild cases of this disorder medication and general hygienic measures suffice, in the pernicious cases the constant vomiting makes it difficult or impossible to medicate or cleanse the intestine. High colon irrigations will relieve the large bowel, but vomiting will continue unless the small bowel is also relieved of toxic products. He has been favorably impressed with the efficiency of the duodenal tube in these cases, and now uses the tube regularly. He employs a modification of the Jutte tube about the thickness of a No. 13 French catheter. The tube is marked at fifty-six cm. (the distance from mouth to pylorus), again at seventy and eighty cm. The tube is introduced into the empty stomach much as a stomach tube, the patient swallowing and breathing deeply as it is gently pushed in. When the first mark has been reached, the patient is placed semiprone on the right side and six to eight ounces of a hypertonic sodium sulphate solution are injected with a glass syringe. The pylorus is thereby relaxed, and after waiting one quarter to one hour the physician pushes in the tube to the second mark, the syringe being used frequently to aspirate during the interval. When none of the fluid introduced is being aspirated, or if bile stained fluid is obtained, the tube is supposed to have entered the bowel, and a litre of a solution of four to six drams of granular sodium sulphate is now slowly injected, with aspiration from time to time to make sure that the fluid is passing in. With a stethoscope over the abdomen active peristalsis can be heard. Within two or three hours copious watery stools, exceedingly offensive, are passed. The tube may be left in place and used for duodenal feeding, but Gray has found the latter super-

fluous, the patients being able to begin taking fluids a few hours after the treatment. It was never necessary to repeat the use of the tube when the patients carried out the hygienic treatment advised. The author does not consider that treatment with the duodenal tube will cure all pernicious cases, for in some hepatic degeneration is always such as to preclude regeneration. The procedure will, however, relieve many cases hitherto refractory. He also advises that abnormal pelvic conditions, such as retroversion, or incarcerated uterus, and ovarian or other tumors, be looked for and corrected, as many cases of mild toxemia occur in which a reflex element exists.

Epidemic Meningitis.—W. T. Connell (*Canadian Med. Assoc. Journal,* October 1916) says that as soon as the diagnosis has been confirmed by lumbar puncture, treatment with a polyvalent serum should be instituted. As much fluid as will flow away freely should be allowed to drain out through the puncture needle, the amount varying from thirty to sixty c.c. in adults, and then by gravity a smaller amount of the serum should be allowed to flow in, from twenty to thirty c.c. being sufficient for the first treatment. At once five to ten c.c. of the serum should be injected intravenously, and about ten c.c. intramuscularly. The intraspinous and intramuscular injections are repeated in twelve hours, and then every twenty-four hours till the fever falls and the symptoms abate.

Treatment of Entamœba histolytica Infection. Clifford Dobell (*Brit. Med. Jour.,* November 4, 1916) reports the effectiveness of treatment with injections of emetine hydrochloride compared with that of the oral administration of emetine bismuth iodide in a carefully controlled series of cases. All of the patients in the first series were given from eleven to fourteen daily injections of 0.065 gram each of emetine hydrochloride subcutaneously and their stools were examined frequently for fairly long periods after the completion of treatment. Of twenty-one patients thus treated only seven were apparently cured, the remaining fourteen all relapsing except five who were not even temporarily freed of amebas. In the relapsing cases the amebas were first found again at times varying from the first to the sixteenth day after the end of treatment. The second series of treatments was carried out in these fourteen uncured cases from the first series. Eleven of these patients were given 0.065 gram of emetine bismuth iodide three times daily, in cachets, for periods of twelve days. Every one of these patients was promptly and apparently permanently cured. The drug was well borne by most, although a few complained of some nausea after taking it. Two of the three control cases treated by a second course of emetine hydrochloride hypodermically in daily doses of 0.065 gram were unaffected by the treatment, while the third had his stools freed of parasites for three days, after which he again relapsed. Two of these same three patients were then treated with the emetine bismuth iodide, and both were promptly cured. Finally, a series of new cases of carriers were given emetine bismuth iodide with cure in all. It was noted in the course of this study that many of the patients were also infected with Entamœba coli, Lamblia and Chilomastix, and in no case were these parasites removed from the feces.

Treatment of Bacillus pyocyaneus Infection. Kenneth Taylor (*Journal A. M. A.,* November 25, 1916) recalls that much trouble in the healing of wounds has been encountered from their infection with the Bacillus pyocyaneus. This organism has proved very difficult of removal from infected wounds. Studies were undertaken to discover a means of ridding the tissues, and it was found that the organic acids seemed specifically inimical to its growth. Of these acetic was the most effective. On the strength of experiments with this and other disinfectants in vitro clinical use was made of a one per cent. solution of this acid in normal saline. Comparative observations were made of the effects of a number of other disinfectants in a large series of cases, but none was found which would remove Bacillus pyocyaneus from the wounds except the solution of acetic acid.

Simple Aseptic Vaccination.—Echlin S. Molyneux (*Brit. Med. Jour.,* November 4, 1916) states that it is possible to eliminate local infections by the following simple technic for vaccination. The skin is thoroughly disinfected by rubbing with methylated spirit; after breaking off one end from a tube of lymph, the end is sterilized in the flame for a moment, and the lymph driven out on the patient's arm by heating the sealed end of the tube with a match. The needle is next sterilized in the flame, the lymph spread, and the skin scarified through it. A piece of sterile gauze is then closely strapped to the patient's arm by wrapping adhesive plaster several times about the arm and pad. This dressing remains in place for five days, when the vaccination is inspected, and a fresh dry dressing of boric lint is applied. With a little practice the method is simple and rapid so that each vaccination requires less than two minutes.

Factors Influencing the Production of Immunity in Vaccination against Smallpox.—L. Camus (*Bulletin de l'Académie de médecine,* October 17, 1916) refers to the highly discordant views hitherto expressed as to the rapidity with which immunity is developed upon vaccination, the necessity for more than a single point of inoculation, etc., and reports illuminating results obtained in experimental intravenous vaccination in rabbits. Immunity appeared constantly on the fifth day in rabbits receiving one c.c. per kilogram of a one in 100 dilution of vaccine. Marked variations appeared, however, when the dose injected was changed. Upon injection of only 0.5 c.c. of a one in 10,000 dilution immunity was complete only on the tenth day, while upon injection of five to ten c.c. of a one to four per cent. dilution immunity was very pronounced by the fourth day, or even a little earlier. Immunization by the cutaneous route led to similar observations. Thus, activity and dose of vaccine are clearly more important factors in the rapidity of immunization than individual peculiarities. While a single pustule may confer immunity as well as six, the time required is much greater, especially if the vaccine is a feebly active one. During an epidemic the use of a strongly acting vaccine seems advisable.

A Successful Method for Correcting Fallen Arches.—C. E. Stephenson (*Indianapolis Medical Journal*, November, 1916) states that he takes an impression of the bottom of the foot with a modelling compound, such as is used in dental laboratories. From this impression a plaster cast is made, being trimmed down before hardening to the shape and length desired, according to the location of the trouble in the particular foot being treated; it is necessary for the arch support to be very much longer when the disorder is in the transverse arch. After the cast is sufficiently dry there is built over it the arch support, using for this purpose a hardening cement which is not affected by moisture, perspiration, or heat under 300 degrees. The amount of cement used is governed by the weight of the patient. After going through a curing process extending over several days' time the arch support has the proper flexibility where it is needed, and is very firm where it is desired to have it rigid. The skeleton of the arch support is then covered with thin leather, giving it a neat finish. This leather covered arch support is light in weight, it does not change in shape as do those made of leather and steel, it is comfortable, and can be remodeled by the aid of moist heat to suit the improved foot. The writer says that the results he has obtained with this method are most gratifying.

Intravenous Tartar Emetic in Kalaazar.—Leonard Rogers (*Lancet*, November 4, 1916) reports that antimony, in the form of tartar emetic, has proved a specific in this very fatal disease, but until recently it has been difficult to give enough of it to cure the disease in man. Rogers has been employing it in the form of a two per cent. solution injected intravenously, and has secured the most striking results. Of eighteen cases so treated thirteen have been cured, two greatly improved, two improved, and one ended fatally from tuberculosis after the parasites had disappeared from his spleen. Two of the patients who were not cured left the hospital before the treatment could be completed, and in the other two the treatment was still being given when the report was made. These results are compared with the usual mortality of seventy-eight to ninety-six per cent. The best results were secured by Rogers from doses of eight to ten mils every three days. Such doses were never given at first, but treatment was usually started with a dose of four mils and the dose increased at each succeeding injection until the patient's tolerance was determined, or until a dose of ten mils was reached. Treatment was continued for a mimimum of several weeks after the fever had disappeared. Great pains were taken in giving the injections to be sure that none of the drug escaped into the subcutaneous tissues, as that accident would cause abscess and retard treatment. The earliest toxic symptom of importance indicating the need for a reduction in dose was found to be vomiting. Under treatment the fever disappeared first, then the parasites could no longer be found in the spleen, and finally the blood picture began to return to normal, and the patient gained weight. In several cases which have been followed up for from four to twelve months since cessation of treatment, there has been no recurrence.

Treatment of Bladder Tumors.—Bernardino Maraini (*Revista de la Asociacion Medica Argentina*, August, 1916) considers that the high frequency current is the treatment of election in papillomata of the bladder. In malignant neoplasms extirpation of the tumor is preferable with high frequency applications to the peduncle. In infiltrated neoplasms which cannot be removed by operation these currents suppress hemorrhage and soothe pain, although they do little good in carcinoma or sarcoma. Advantages of the high frequency treatment are that no anesthetic is necessary; the operation is done in sight; there is produced neither pain, reaction, nor hemorrhage; there is no ulceration nor scar; the patient can continue his usual occupation; and the destruction of the tumor can be carefully watched through the cystoscope. Slight disadvantages are the length of time required, the possibility of increasing vesical irritability in cystitis, and the difficulty of the technic in certain locations of the tumor.

Method of Injecting the Facial Nerve for Spasm.—George M. Dorrance (*Journal A. M. A.*, November 25, 1916) writes that it is absolutely essential to differentiate carefully between true facial spasm and the tics, since the treatment by injection is contraindicated in the latter conditions. Spasms are limited to the motor mechanisms, cannot be imitated voluntarily, cannot be inhibited voluntarily or by strong emotions, involve the entire distribution of the facial nerve, are painful to the patient, and are often limited to parts of a muscle, depending upon its innervation and the extent of the development of the spasm. The most satisfactory treatment for facial spasm is the temporary paralysis of the entire facial nerve at its exit through the stylomastoid foramen. The usual technic for its injection is fraught with considerable risk of perforation of the jugular vein and is inaccurate, often requiring many punctures for success. On the strength of these facts the author has devised a simple, easy, and safe method of injection. A trocar and style needle ten centimetres long and four tenths centimetre in diameter is inserted at the angle of the jaw through an anesthetized area, novocaine being used for this purpose. The needle is directed upward and backward until the tip strikes the base of the mastoid, which can be determined by palpation with the finger. The handle of the needle is then elevated and its point made to pass backward, inward, and a little downward until it can be felt to enter the stylomastoid foramen. The style is then removed and if no blood flows a little over two mils of seventy per cent. alcohol is injected. If the needle is in the foramen there will be immediate paralysis of the entire facial nerve. Some discomfort is associated with this paralysis at first and it is necessary in the beginning to guard against the drying of the cornea on the paralyzed side owing to the loss of the wink reflex. All spasm and associated pain is at once relieved. The muscles of the face should be massaged to prevent their wasting, and in a few weeks to several months the function of the nerve returns completely. In some cases spasm returns some time after the restoration of function, and it is then necessary to repeat the injection.

Mouth Disinfection in the Prophylaxis and Treatment of Pneumonia.—Wadsworth (*Journal of Infectious Diseases,* October, 1916) reports an extensive study of the action of various mouth washes upon the pneumococci, the result being that the commercial solutions examined proved very unsatisfactory. The combination that proved most effective was one containing thirty per cent. of alcohol combined with glycerin in an isotonic solution of alkaline salts. After using this latter as a mouth wash, pneumococci were not found in the secretions under normal conditions.

Streptococci from Scarlatinal and Normal Throats.—Ruediger (*Journal of Infectious Diseases,* October, 1916) reports that he finds streptopyogenes constantly and in abundance on the tonsils of patients suffering from tonsillitis and scarlet fever, if examined before the inflammation of the throat has subsided. There is also present in all normal, and in nearly all diseased throats, a large group of organisms which lie between the typical streptopyogenes and the pneumococcus. This group can be differentiated from the latter, both morphologically and culturally. They have very little virulence for rabbits and appear to be normal inhabitants of the throat.

Treatment of Pneumonia.—B. S. Price (*American Journal of Electrotherapeutics and Radiology,* September, 1916) states that during the stages of engagement and of hepatization, thermopenetration, properly conducted, gives prompt relief, and decreases the mortality percentage. With the patient reclining, two uncovered metal electrodes are placed at opposite points over the involved area. They should be warm and dry. When the diseased tissue lies midway between them, they should be of equal size, viz., seven by eight inches. When the tissue lies much nearer one of the electrodes, that one should be larger. If both lungs are involved, the electrodes may be placed laterally. A hot wire metre reading of ten milliampères is comfortable to start with. After four or five minutes, or as soon as perspiration sufficient for good conduction has supervened, the milliamperage may be augmented to 1700 or 2000, to be continued for twenty to thirty minutes, in the stage of engorgement, and to 1400 in the stage of hepatization. The effects consist of diminution in dyspnea, cough, pain, distress, cyanosis, and nervous excitability, and a softening of the pulse and deepening of respiration. The patient usually sleeps comfortably after the treatment. In a moderately severe case the treatment should be repeated in six hours, and thereafter every eight hours till resolution is established—usually within forty-eight hours in consolidation cases. Still better results in cases associated with nephritis, arteriosclerosis, or intestinal toxemia, are obtained by administering an oven bath two hours after the first thermopenetration treatment. A temperature of 450° F. of the oven air should be quickly reached and maintained until the pulse slows and softens (if previously tense and full). The patient is then transferred without exposure or effort to water at 107° F., and finally placed in bed, where he sleeps several hours. He feels and is much better on awakening. The temperature, as a rule, drops several degrees in a few hours, and almost always resolution becomes established within twenty-four hours. When both thermopenetration and oven bath are applied daily, the former need be given only every twelve hours. Occasionally, in intense engorgement with arteriosclerosis, venesection is beneficial. Calomel should be given at the outset, followed by a saline, or castor oil if the stomach will tolerate it.

Penetrating Wounds of the Abdomen.—T. Crisp English (*Lancet,* October 28, 1916) concludes from an experience in seventy-one cases that operations for such wounds are undesirable unless they can be done under good surgical surroundings and by an experienced operator; for if these conditions are not fulfilled failures will be commoner than successes. It is most important to have the patient sent to a satisfactory operating station as soon as possible if the transportation can be made with reasonable safety. Patients with a pulse rate above 130 had better not be moved, but should be kept absolutely quiet, warm, and continually under the influence of morphine. They should also be given saline infusions, either by rectum or otherwise. Where the patient's condition is not favorable for operation the same plan should be adopted until improvement has taken place. No patient with a pulse rate above 140 should be subjected to operation. In giving morphine the indication for the size and frequency of the doses should be the degree of pain. The operation itself should be performed as expeditiously as possible and such steps should be taken as the individual case demands, but these will be chiefly intestinal suture and resections. Of the seventy-one patients operated upon only thirty-nine recovered.

Treatment of Wounds.—M. Winands (*Medizinische Klinik,* October 8, 1916) states that the general methods employed in the dressing of wounds, whether they are aseptic or suppurating, bring gauze or other similar material into direct contact with the surfaces and particularly with the edges of the wounds. The disadvantages of this are many, but the most important are that the dressings become adherent to the surface at the margins and their removal interferes with epithelialization and delays healing; the removal causes more or less pain; and, finally, the dressings become saturated with the discharges, which then dry and confine the remaining discharges so that the wound macerates in them. These unfavorable conditions can be overcome readily by treating the wound or ulcer with the desired remedy, applying to the edges and for some distance beyond them to the healthy skin some form of oily salve, such as zinc oxide, and covering the whole area with a sheet of gutta percha with extends beyond the margins of the wound. Over this is applied a sterile dry gauze dressing to absorb the secretions which escape between the gutta percha and the greased skin. Such a dressing can be left in situ for many days, only the outer layers of gauze being changed when they become soiled. Under such a dressing the wound becomes clean, healthy, and covered with bright red granulations over which the epithelium extends rapidly. This form of dressing has the further advantages of economy, of immobilizing the wound area, and of yielding pliable, soft scars.

Treatment of Gonorrheal Iritis by Polyvalent Vaccine.—S. G. Mansilla (*Revista de Medicina y Cirugia Practicas,* October 14, 1916) reports a case of iritis occurring in a man with an uncured gonorrheal urethritis of fourteen years' standing which was successfully treated with polyvalent gonococcus vaccine. The local reaction in the eye was violent following each injection, but the ultimate result was excellent.

Nitrous Oxide Analgesia and Anesthesia in Obstetrics.—Elmer L. Henderson (*American Journal of Surgery,* November, 1916) states that in nitrous oxide gas we have a safe and efficient analgesic which is worthy of general adoption in obstetrical practice, and one which clearly refuted the Biblical proclamation that "in sorrow thou shalt bring forth children," although the credit for painless labor has hitherto been claimed by Gauss and his *Dammerschlaf.*

Tuberculin in Ocular Tuberculosis.—R. B. Metz (*Cleveland Med. Jour.,* September, 1916) in a group of cases of ocular tuberculous manifestations records excellent therapeutic results, so far as the eyes were concerned, from the use of tuberculin in graded doses. The administration of tuberculin brought about apparent cure or marked improvement in five cases which were not benefited by the routine methods of treatment. The cases benefited or cured included two of phlyctenular conjunctivitis, one of phlyctenular conjunctivitis and scleritis, two of sclerosing keratitis, and one of sclerochroiditis.

Collosol argentum.—A. H. Boys (*Brit. Med. Jour.,* October 28, 1916) reports excellent results obtained from the use of this remedy in the following cases. A single subcutaneous dose of one mil cured a severe case of pyorrhea. Two drops placed in the conjunctival sac cured a case of acute ocular inflammation with corneal ulcer. Daily injections of 1.3 mil subcutaneously cured a case of postoperative suppuration and septic diarrhea. Oral doses of 0.6 mil cured suppurating tuberculous cervical glands in a child of three years. Finally, great improvement followed the subcutaneous administration of 1.6 mil of collosol argentum on alternate days in a case of pulmonary tuberculosis in an adult.

Treatment of Syphilis of the Central Nervous System.—I. C. Walker and D. A. Haller (*Archives of Internal Medicine,* September, 1916) report on seventy-five patients in whom three therapeutic methods—intravenous salvarsan alone, intraspinal salvarsanized serum alone, and the two procedures combined—were compared. The cases comprised forty-eight of tabes dorsalis, six of general paralysis, sixteen of cerebrospinal syphilis, and five of syphilitis meningitis. To them 450 intraspinal injections and 350 intravenous doses of salvarsan were given. The mode of preparation of the salvarsanized serum for intraspinal use was that of Swift and Ellis, save that larger doses of intravenous salvarsan—usually 0.5 and 0.6 gram—were given, the blood withdrawn one half instead of one hour later, and for the intraspinal injection from twenty to twenty-five c. c. of the whole serum instead of a diluted serum used. The results of the treatment showed that patients with recent syphilitic meningitis and cerebrospinal syphilis may be relieved symptomatically by intravenous salvarsan; the spinal fluid Wassermann reaction may become negative with one c. c. and the cell count normal. In patients with long standing cerebrospinal syphilis or tabes, however, though they may be benefited symptomatically by intravenous salvarsan, little or no change takes place in the spinal fluid. Patients with any of the syphilitic nervous diseases, recent or late, are much improved by combined intravenous salvarsan and intraspinal salvarsanized serum. Those in whom salvarsan alone fails, do improve both in symptoms and spinal fluid findings after the combined treatment. In many patients with negative serum reaction, but positive spinal fluid findings, the spinal fluid Wassermann and the globulin (Noguchi) test, become negative, and the cell count normal, following sufficient intraspinal treatment alone. In such patients the authors now dispense with intravenous salvarsan entirely. All patients with positive serum Wassermann are first treated with intravenous salvarsan alone.

Luargol, Dausz's New Antisyphilitic.—P. Pollio and C. Ruhl (*Riforma medica,* November 6, 1916) after the use of luargol in twenty-six cases conclude that its action is comparable to that of salvarsan and neosalvarsan, and that it is of service in all three stages of the disease. In addition to its antiluetic action it has a certain reconstructive efficacy which is of help in cases of syphilitic cachexia. Doses of 0.15 to 0.3 gram given every three to five days were well borne, but it is well to begin with small doses of 0.1 to 0.15 gram given in at least 100 to 150 c.c. of water.

Galyl in the Treatment of Syphilis.—Gordon Bates (*Canadian Journal of Medicine and Surgery,* December, 1916) states that he has used galyl for syphilis since salvarsan and neosalvarsan are not obtainable. It is a derivative of arsenobenzol, its full chemical name being tetraoxydiphosphoaminodiarsenobenzene. It contains 35.3 per cent. arsenic, and 7.2 per cent. phosphorus. It is a yellow powder and comes in ampoules of 0.4 gram each. It is insoluble in distilled water, but readily soluble after a small quantity of sodium carbonate has been added. It is administered in a similar manner as neosalvarsan, the contents of an ampoule being dissolved in distilled water (ten c.c.) and given intravenously by means of a ten c.c. syringe. The dose for an adult male is 0.3 gram; for a female, 0.25 gram. The contraindications include grave alterations in the heart and bloodvessels and serious disturbances of the central nervous system from e. g., far advanced general paresis, alcoholism, diabetes, or pulmonary tuberculosis. These contraindications are only relative, and usually small doses can be used. The author has used fifty-five tubes and concludes as a result of his experience: 1, clinical symptoms clear up rapidly; 2, the Wassermann reactions become negative as a rule in approximately the same time as with salvarsan or neosalvarsan; 3, that there is little reaction. Three cases showed nausea and in several cases there was a slight rise of temperature immediately after the treatment; 4, there is no evidence of thrombosis in veins following treatment. [We are informed that a small quantity of galyl has been imported recently.—Eds.]

Miscellany from Home and Foreign Journals

Further Studies on the Protein Poison.—Victor C. Vaughan (*Journal A. M. A.*, November 25, 1916) reports certain of the advances which have been made during the last year in the knowledge of the nature of the protein poison. It is pointed out that the peptone poison, proteoses, and the protein poison are closely related chemically, and that, probably, the active groups in all are identical or closely related. All proteins have been found to yield a poisonous group, which is the same or closely similar for all. The poison has been shown not to be betaiminoazolylethylamine, or a cholin derivative, but to be a derivative behaving much like the globulins. When proteins are fragmented to yield the poison the poisonous fragment gives the biuret test in much higher dilutions than do the residues; the same is true of its response to the xanthoproteic test, the Millon reaction, the Bardach test, and the ninhydrin test. The poisonous fragment fails to give the Molisch test, the Hopkins-Cole test, Benedict's modification of this test, and the benzaldehyde test. The results of these tests of the poisonous fragment show that it contains amide groups, benzin nuclei, and a high concentration of the monohydroxybenzin nuclei, but no carbohydrate groups. Finally it has recently been shown that substances in every way similar to the protein poison can be extracted from normal tissues such as brain, heart, lungs, spleen, liver, etc., and especially from the voluntary muscles. This latter finding suggests their occurrence as normal metabolic products, and their possible association with acidosis, eclampsia, uremia, etc., remains to be determined.

The Possibility of Lowering Gastric Acidity by Means of Diet.—P. I. Denisova-Suchevskaja (*Roussky Vratch,* July 9, 1916) cites a large number of authors to show a division of opinion with regard to the effect of diet on hyperacidity. While some gastroenterologists assert that a diet rich in meat and eggs diminishes hyperacidity by combining with the free hydrochloric acid, others maintain that such a diet stimulates gastric secretion and recommend a carbohydrate and hydrocarbon diet as the most suitable. Still others are of the opinion that diet has no effect one way or the other, the point of greater importance being the quantity of food given. His own conclusions are that a diet of vegetables and fats is of value in the treatment of hyperacidity because it remains in the stomach for a short time and does not stimulate gastric secretion, but brings about a permanent reduction of acidity. These conclusions are based on observations made in Professor Iarotzky's clinic The diet, as recommended by Professor Iarotzky, consists of the whites of three to four eggs in the morning and sixty to eighty grams of butter in the afternoon. In a day or two the whites of two eggs and forty grams of butter, unsalted, are given in addition, so that in about a week the patient receives the whites of eight eggs and 140 to 160 grams of butter daily. This diet contains about 1700 calories. In severe cases, and in gastric ulcer, the treatment is begun with the white of one egg and twenty grams of butter a day. Under this diet the patient neither asks for nor receives water. If thirst is excessive, enemas of sugar in water are given. In about ten days or two weeks, the whites are reduced to three or four, the butter to sixty or eighty grams and a limited amount of carbohydrates and fats added. These consist of puree of potatoes, rice, farina, and oatmeal, with butter. Later, vegetables well cooked and mashed, with the addition of butter but without salt are added. A number of cases are described in detail, showing that this dietetic regimen brought about a marked reduction of the hyperacidity and improvement of the symptoms.

Chronic Digestive Disorders in Children.—Charles Gilmore Kerley and Leon Theodore Le Wald (*Journal A. M. A.*, November 25, 1916) report that a study of a series of children with such chronic digestive disorders as repeated attacks of acute indigestion with vomiting, abdominal distention, repeated attacks of intestinal colic, habitually loose movements, extreme constipation, etc., showed that in a considerable proportion the disturbance was due to some anatomical abnormality in the alimentary canal which was discovered by means of the x ray. The conditions most frequently found were elongated sigmoid, colonic ptosis, pyloric obstruction, or combinations of these. Eighteen illustrative cases are reported. Treatment by relief of constipation, massage, gymnastics, suitable regulation of the diet, both as to amount at each feeding and as to composition, and the application of a modified Aaron band gave good results in most of the cases.

A Study of Diarrheas in Boston.—Joseph I. Grover (*Journal A. M. A.*, November 25, 1916) states that the records of the outpatient department of a children's hospital for one year were analyzed with respect to the diarrheas, a total of over 14,000 visits, about 3,500 new cases being included. Of this number there were 588 cases with diarrhea. There was nothing characteristic found in the topographical distribution of the homes of the patients. Males constituted fifty-six per cent. of the total. More than eighty per cent. of the cases occurred in children and infants who were below normal weight. The prognosis was found to be less favorable in infants born prematurely or much underweight than in others. Of the total of 588 cases, 347 occurred in children less than one year old, and 143 in those between one and two years old. The largest number of cases developed between the ages of two and four months. There was a close relation between the onset of the diarrhea and the time of weaning, showing that the more recent the weaning, the more likely was there to be diarrhea. The seasonal occurrence was greatest from July to September, inclusive. The occurrence of diarrhea seemed to be somewhat related to the height of the temperature, but much more closely to that of the humidity. This factor was the most constant single one encountered

in the study of causes, especially that of the absolute humidity. The curves of this and of the incidence of diarrhea were almost parallel. In the diarrhea babies less than one year old only fourteen per cent. were wholly breast fed at the time of the illness, fifteen per cent. were on mixed breast and artificial feeding and seventy-one per cent. were wholly artificially fed. In the majority of the patients over one year of age the diet was faultless and could not be blamed for the diarrhea. In those below one year of age a large majority—excluding the breast fed—were being fed some fermenting food element in excess, and one third of all of the infants with diarrhea were receiving some form of proprietary food, excluding from such classification only lactose, Mead's dextrimaltose, Brooks's and Robinson's barleys, sucrose, and malt soups. Fifty-seven per cent. of all of the diarrheas in infants under one year of age on the bottle wholly or in part were due to carbohydrate fermentation.

Diagnosis of Abdominal Distention in Children.—Louis Fischer (*Medical Record,* November 25, 1916) remarks that abdominal distention is found in Hirschsprung's disease, in tuberculous peritonitis, in malignant new growths, especially sarcomata involving the kidney, and in cirrhosis of the liver. Enlarged spleen may cause distention, as may rickets, Potts's disease, hydronephrosis, typhoid and pneumonia. A marked leucopenia of 4000 to 6000 with distended abdomen should be suspected to be of typhoid origin even in the absence of the Widal and diazo reactions. In all cases of abdominal distention a rectal examination is imperative, while suspected pyloric obstruction calls for a bismuth meal and x ray examination. Colicky pains with tenesmus without expulsion of flatus or stool, but with jellylike blood tinged evacuations immediately point to intussusception. Great rapidity is characteristic of the course of acute abdominal inflammation in children and great care, therefore, is required in diagnosis with special attention given to the lungs, particularly the lower lobes.

Blood Pressure and Pulse Rate in Soldiers in the Trenches.—Pierre Menard (*Bulletin de l'Académie de médecine,* October 17, 1916) reports observations made for a period of eight months in twenty subjects, aged thirty-six to forty years. Irregularity was a feature in the curves obtained. The pulse pressure in a single subject varied under different circumstances from fifteen to fifty mm. of mercury. In the first line trench, 150 metres from the enemy both systolic and diastolic pressures were usually lessened, the pulse pressure itself diminishing slightly. Explosion of a large shell close at hand caused a distinct rise in the systolic, diastolic, and pulse pressures, which returned to normal within an hour. Fatigue and overwork always lessened the pulse pressure, and nearly always increased the diastolic. Blood pressure measurements are considered to afford the best criterion of fatigue requiring rest from active duty. Of ten subjects, seven showed regularly a higher pulse rate in the first than in the second or third line trenches. In one the pulse was unchanged and in the remaining two, slowed in the advanced trenches, in one instance to from forty-eight to sixty-four a minute. Fatigue usually slowed the pulse rate.

Acute Adrenal Inflammation in Pernicious Malaria.—G. Paisseau and H. Lemaire (*Bulletin de l'Académie de médecine,* October 17, 1916) report that in certain pernicious malarial paroxysms they noted signs suggestive of adrenal involvement, such as low blood pressure without disturbance of cardiac rhythm, vomiting, diarrhea, lumbar and abdominal pains, and the Sergent-Bernard white line phenomenon. In three autopsies marked adrenal changes were found, with only slight lesions in the kidneys, liver, and spleen. The authors divide the adrenal changes of malaria into three groups. There is, first of all, functional insufficiency, as shown by the absence of spongiocytes in the adrenal cortex. In addition, there may exist more or less diffuse cellular degeneration in the cortex, at times passing into complete cytolysis. Finally, there are noted hemorrhagic lesions, in conjunction with the preceding changes. The hemorrhagic foci may be microscopic, or may contribute the chief lesion, and are due to vascular thrombosis. The malarial plasmodium is found in the diseased adrenals, though it may disappear from quinine treatment, thus probably accounting for certain late deaths in algid malaria where the parasite is no longer found in the blood. Mild adrenal involvement may possibly occur in the ordinary type of paroxysm, and in some cases of chronic malaria. At all events, not only quinine, but also epinephrine is indicated in algid malarial cases.

Origin of Anaphylaxis.—L. C. Soula (*Presse médicale,* October 23, 1916) lays stress on nervous disturbances in the development of the anaphylactic state and in anaphylactic shock. Clinically the latter is essentially characterized by nervous phenomena, whether motor, respiratory, or digestive in their manifestations. Besredka has shown that the anaphylactic shock following the second injection of foreign albumin can be prevented by etherization. Soula, moreover, working with Abelous and Bardier found that section of a sciatic nerve or hemisection of the spinal cord in the rabbit markedly sensitizes the animal to subsequent injection of certain albumins. Chemical researches showed that in any animal that has received the first sensitizing injection of a foreign protein, definite chemical changes occur in the nervous tissues, without the least objective clinical sign of such a transformation. The proportion of free aminonitrogen and of polypeptid nitrogen in the brain and cord of such an animal increases progressively to the twentieth day, at which sensitization is greatest, and return to normal by the thirty-fifth day, when sensitization has likewise disappeared and can, moreover, not be reproduced by a further injection. The anaphylactic state thus apparently involves an autolysis of a certain number of neurones in the living organism. The associated excessive protein destruction can be traced in the urine. In addition, Soula finds that the amount of soaps in the nervous tissues in sensitized animals is increased; likewise, the elimination of calcium in the urine. The increased amount of nucleoalbumins detected leads to the view that, after the initial toxic attack by foreign protein, the nervous tissues react to the destruction of adult nerve cells by the formation of new neurones.

Carcinoma of the Superior Tarsal Cartilage.—S. G. Mansilla (*Revista de Medicina y Cirugia Practicas,* September 21, 1916) reports a case of this extremely rare condition in a woman fifty-two years of age. Excision of the mass with plastic repairs of the eyelid gave a good result except that there was a shortening of the upper lid which interfered with closure of the palpebral fissure.

Eclampsia.—Albert T. Griffiths (*Bulletin of the Department of Public Charities,* October, 1916) gives his opinion that early diagnosis on sound principles offers the keynote to success. In the treatment, five points should be borne in mind: 1, Regulate and limit the food of the patient; 2, stimulate all excretory functions; 3, keep the alkalinity of the blood plasma normal; 4, regulate the blood pressure; 5, do not delay the delivery.

Experimental Observations on the Pathogenesis of Gallbladder Infections in Typhoid, Cholera, and Dysentery.—Nichols (*Journal of Experimental Medicine,* November, 1916) shows by his experiments upon rabbits that the production of gallbladder lesions in typhoid by descending infection of the bile from the liver readily occurs. The same mechanism probably holds good in cholera and dysentery. He reports also that the rabbit bile was antiseptic in its action, and as this power appeared to be in direct proportion to its alkalinity it is suggested that alkaline therapy be used in the prevention and cure of chronic carriers.

Syphilis with Neurological Symptoms Simulating Other Conditions.—D. A. Haller and I. C. Walker (*Journal A. M. A.,* Nov. 18, 1916) emphasize the importance of doing a Wassermann test as a routine measure, and report three cases in which the correct diagnosis would not have been made without its aid. The first was that of a man with an old trifacial neuralgia and some facial palsy; the second was a similar case in a woman, the trigeminal neuralgia not, however, being accompanied with a palsy; the third was a case of what was apparently idiopathic epilepsy. In all three cases the syphilitic nature of the condition was discovered as the result of a routine Wassermann test, and confirmed by cure of the condition in each under antisyphilitic treatment.

X Ray Diagnosis of Gaseous Accumulations in the Tissues.—De Keating Hart (*Paris médical,* October 14, 1916) points out that gas in the tissues, as in gas gangrene, can, as a rule, be easily recognized with the x rays, even when not larger than a pea. In some instances the diagnosis of gas accumulation can thus be made earlier than the clinical diagnosis, though exceptionally, when the gas is diffused in small bubbles, it may be invisible in spite of manifest clinical signs. Gas accumulations are characterized in the plate by their white centre and darker periphery. A punched out loss of bony or soft tissue may be confusing, but can be differentiated by moving the affected part in various directions, when a gaseous aggregation will remain unchanged in appearance, whereas a loss of substance will assume more or less the aspect of a truncated cone, show its connection with a superficial wound, or become attenuated where involved bone is turned in certain directions. In the abdomen, deep breathing will differentiate a mobile gas inflated loop of bowel from a gaseous pocket in the abdominal parieties. In thoracic wounds a tangential direction of the rays over the affected surface will permit of a decision. Study of therapeutic oxygen injections in gas gangrene showed that the gas, as ordinarily used, tends to follow a single muscle sheath; greater efficacy can be secured by injecting separately each muscle sheath in the region under treatment. The extremely clear radioscopic images given by therapeutic intramuscular gas injections and by pathological gas accumulations along groups of vessels and nerves permit of using the x rays in the exact diagnosis of muscular, osseous, nervous, and vascular lesions.

Dental Diseases in Nursing Women.—Harold Waller (*Lancet,* November 4, 1916) states that the malign effects of dental disease are generally quite widely recognized, but their effects in nursing women are far too little appreciated. From an experience of nearly 200 nursing women with dental disease the author is convinced that this affection plays an important role in the health of both mother and child. He cites instances in which the removal of carious teeth, and the cure of root abscesses completely cured the complaints of both parent and child. The commonest effects observed were weakness, anemia, and deficient nutrition on the part of the mother, with a marked inability to continue nursing. The infant was affected by vomiting, restlessness, refusal to nurse, and failure to gain weight normally. The physical phenomena, chiefly the condition of weight, being capable of exact measurement, were studied in relation to oral sepsis, and it was found that many infants who were backward in development at once began to gain normally when the mother's mouth infection had been cleared up.

Possible Functions of the Cerebrospinal Fluid.—W. D. Halliburton (*Lancet,* November 4, 1916) states that this fluid differs only slightly in composition from Locke's solution, and represents an extremely simple physiological saline fluid which contains only those additional substances which are essential for the nutrition of the nervous tissues. It is secreted actively by the ependymal cells of the choroid plexus and its pressure is regulated by these cells and by the state of the circulation. It is removed by absorption into the venous sinuses through the microscopic arachnoid villi. The secretion of the fluid can be increased by three groups of substances, excess of carbon dioxide in the blood, or want of oxygen; by the volatile anesthetics; and by an extract of the choroidal tissue or of the brain. With certain limitations and differences the fluid may be regarded as the lymph of the brain, but it differs essentially in being secreted specifically, and not merely in response to osmotic changes. The cells which secrete it are very highly selective in the materials which they reject, on the one hand, and allow to pass, on the other. This is probably an expression of Nature's effort to protect the delicate nervous tissues from all harmful agents, and to surround them only with the most perfect physiological fluid possible.

Proceedings of National and Local Societies

ASSOCIATION OF AMERICAN PHYSICIANS.

Thirty-first Annual Meeting, Held at Washington, D. C., May 9, 10, and 11, 1916.

The President, Dr. HENRY SEWELL, of Denver, in the Chair.

(*Continued from page 1121.*)

Acidosis—(*Continued.*)—Dr. C. F. HOOVER, of Cleveland, said that one point bearing on the relation between acidosis and carbon dioxide tension of alveolar air needed to be emphasized: there seemed to be an impression that there was a definite relationship between carbon dioxide tension of alveolar air and the amplitude of ventilation. There was no such definite constant relationship.

Dr. H. A. HARE, of Philadelphia, naturally felt somewhat timid about speaking as a clinician after men so respected in the biochemical and physiological fields. Doctor Janeway had alluded to the attenuated atmosphere at the altitudes reached in the discussion; but he reflected that the navigator derived much useful information from the astronomer without seeking the astronomer's glory. He had hoped to learn how to apply what had been said to the treatment of acidosis of whatever type; but he confessed to disappointment, except in the matter of the use of alkalies. Thirty years ago he had learned in Ludwig's laboratory that the blood was the most carefully protected tissue of the body, and that they should be careful to do no harm by introducing strange substances into it. This warning should be heeded in view of what had been said about the harmful effect of too active alkali therapy in acidosis. This association has a grave responsibility to the practitioners of the country. While he had not been able to follow the Allen treatment entirely in the management of his diabetics, he had learned not to be alarmed at the appearance of acetonuria during the course of starvation.

Dr. LAWRENCE J. HENDERSON, of New Haven, said that the speakers had been too kind in their appreciation of his theoretical and *a priori* remarks. But more than one of these ideas had been proved true; therefore there must be something in the underlying theory. At any rate it was clear that in a great variety of diseases there was a loss of ability to protect the blood against acids; and this condition ought to be called acidosis. He wished to say further: 1. Because alkalies had been abused was no reason for refusing bicarbonates in small quantities and over long periods; for bicarbonate was the *third* constituent of the blood; 2, while acidosis could not be held to be the cause of disease, it could be held to be the cause of symptom complexes in disease; for one, he believed that acidosis was the cause of diabetic coma. It was possible to overcome the acidosis of diabetic coma without curing the condition, as had been pointed out. This might be due to the fact that the cells of the body were not so readily and quickly influenced by substances introduced into the blood in treatment; and evidence of acidosis might disappear from the blood while the condition persisted in the tissues.

Treatment of Typhoid Fever by Intravenous Injections of Sensitized Typhoid Vaccine Sediment.—Dr. FREDERICK P. GAY and Dr. H. T. CHICKERING, of the University of California, presented this report, which dealt with slight amplifications of cases already reported, a number of additional cases, and a continuation of laboratory studies. The series consisted of about seventy-five cases of typhoid fever verified by blood culture and Widal tests. The majority were treated with intravenous injections of polyvalent, sensitized vaccine sediment, already recommended by Gay and Claypole for prophylactic use. Routine treatment, apart from the specific treatment, varied, as the cases occurred in the practice of a number of physicians, and were treated both in hospitals and in private houses. The mortality was about the same as the best hospital normal, nine to ten per cent. Distinct benefit as seen in cutting short the disease followed the treatment. Over forty per cent. of the cases were abortively cured, normal temperature prevailing within a week after the first injection. In twenty-five per cent. more of the cases an early, induced lysis was observed. The nature of the reactions produced and the correlation of the severity of the disease, and the blood findings in relation to the results produced were considered. Suggestions for further perfecting the method were made.

Dr. LOUIS M. WARFIELD, of Milwaukee, said that through the kindness of Doctor Gay he had obtained the vaccine described in the paper for use in a recent typhoid epidemic in Milwaukee. The epidemic was virulent. The vaccine was obtained late in the epidemic and only twenty-one cases had been treated when the epidemic was over. Of these twenty-one cases, sixteen ended in recovery; two cases were cut short abortively, the patients being a man of forty years and a child; the man suffered a typical relapse, which was uninfluenced by the vaccine. The five deaths were due: Two to pneumonia; two to hemorrhage; and one to long continued toxemia. The average duration of fever in this series was thirty-eight days, the same as in the prior series of unvaccinated cases. The shortest vaccinated case was seventeen days; the shortest unvaccinated case, sixteen days. The highest leucocytic crisis took the count to 42,000 and occurred five hours after vaccination. Two impressions were gained: 1. The general course of typhoid was milder after vaccination; 2, the subjective symptoms were ameliorated.

Dr. JOSEPH L. MILLER, of Chicago, said that nonspecificity of the reaction needed emphasis. Ludke had as good results from the use of albumose as from vaccine. He himself had seen as good results from the use of proteose. Recently he had seen remarkable quick recoveries from acute infections follow the use of chicken serum. In acute arthritis he had been able to induce very striking crises with injections of typhoid vaccine.

The Physical Signs and Symptoms of Wounds of the Chest.—Dr. C. P. HOWARD, of Iowa City, presented a series of 107 cases, of which eighty-seven were thoroughly studied. The wounds were produced by rifle or machine gun bullets (forty-

five) or by shell as shrapnel, high explosive, or hand grenade (forty-two). In one group of fifteen no signs could be found; in another group, either pneumonia (four) or simple serous effusion (two). In a third group, mediastinitis, one case. In a fourth group a hemothorax was found, which was either infected (nine cases) or noninfected (fifty-six cases). Infecting organisms varied. Symptoms were cough, pain, hemoptysis of varying degree, and dyspnea. There was usually fever. The physical signs suggested consolidation rather than fluid, owing to the great compression of the lung. Cardiac displacement was often striking. In eight cases there were unequivocal, and in five others suggestive signs of pneumothorax. In four cases pneumonia existed on the side opposite to the hemothorax. Secondary hemorrhage into the pleural cavity was rare (one case only). Simple fibrinous pericarditis occurred in three cases, and in one a pneumopericardium. Treatment consisted of free drainage in infected cases and of simple aspiration or of oxygen replacement. The mortality was only seven per cent. in the entire series.

Dr. David Riesman, of Philadelphia, said that the same physical signs described by Doctor Howard as occurring in hemothorax from gunshot wounds he had observed in traumatic hemothorax without penetration. As to the treatment, the patients were left alone and got well by absorption.

Anaphylatoxins.—Dr. F. G. Novy and Dr. P. H. DeKruif, of Ann Arbor, observed that the study of anaphylatoxins was made necessary because the study of immunity could go no farther until the problem of anaphylaxis was solved. An anaphylatoxin was a toxic substance developed in an organism as a result of the introduction into that organism of any one of various things. What were the conditions under which this substance was formed? To determine this, a number of antigens or inducers were used; agar was chosen as a good general reagent. It was now possible to make a constant anaphylactic poison which would kill a 250 gram guineapig immediately in dose of 0.25 c. c. If agar serum anaphylatoxin was centrifugated, it might be used without harm; after fifteen minutes it killed; and this might be repeated: it was a true colloidal periodicity. But it was found that normal serums were all deadly poisons if treated properly. Normal blood serum, which was harmless when freshly drawn into a syringe and for one or two minutes thereafter, after three minutes always killed. Rabbit's blood was divided into two portions; one part defibrinated by beads was harmless; another part defibrinated with a rod, always killed. If serum could be so influenced out of the body, why not in it? The answer was found in the production of a constant poison by the use of agar as antigen, but only when it was employed in a certain way.

The Food Problem in Dispensary Patients of Different Nationalities.—Dr. H. R. M. Landis and Dr. F. A. Craig, of Philadelphia, recalled that the diet of the populace was an important factor in social medicine. The proper utilization of food had an important bearing on the prevention of disease, notably tuberculosis. Were the people getting the right kind and amount of food for their money? Were foreign born dispensary patients adapting themselves well to American market conditions? A study was made of four groups of families: Three Italian, three Jewish, three negro, and three Polish. Daily inventories of their food supply were made for three weeks by a nurse, and the calories, waste, and cost estimated. Adopting a standard caloric value, including 340 calories represented by protein, it was found that all the groups approximated the desired caloric value in the food purchased, but there was much variation in the protein content. The cost per capita per diem was as follows: Italians, nineteen cents; Jews, 21.5 cents; negroes, twenty-four cents; Poles, thirty-four cents. Thus it cost the Poles nearly twice what it cost the Italians to obtain food of the same nutritive value. The solution of the problem for the sick lay with the visiting nurse and the social worker; for the community, it must be solved in community school centres with instruction in food values and costs, etc. The food habits of the poor were as important as were housing conditions.

Dr. S. Solis Cohen, of Philadelphia, would ask Doctor Landis to make one slight correction, viz., instead of the word Jews, to insert the word Russians. Those of the Jewish faith who had been in this country for two hundred and fifty years objected to being called aliens. He thought the caloric content by no means represented the true value of food, especially of its dietetic value in tuberculosis. He had long been convinced that the therapeutic value of food in tuberculosis depended upon its richness in nitrogen rather than the other ingredients.

The Etiology of Pellagra.—Dr. E. J. Wood, of Wilmington, N. C., viewed the subject from the standpoint of a deficiency, but this deficiency was regarded as more specific than had been generally thought. Corn was regarded as bearing the same relation to pellagra as did rice to beriberi. The correctness of this view was proved both by experiments on the pigeon and by evidence found in the literature of outbreaks of pellagra brought about by eating highly milled meal, which were promptly corrected by feeding whole meal. The fault lay in two factors. The first was the heating of the corn in kilns above 120° C., which was enough to destroy the vitamine. The second was the removal of the fat containing germ from the grain. The remedy consisted in feeding the victims the whole grain and this plan was also prophylactic.

Dr. Joseph Sailer, of Philadelphia, said that for a long time pellagra had been growing in importance in this country, and it now needed to be kept constantly in mind by physicians in the north as well as in the south. He had recently seen two cases in Philadelphia, one in a white woman, one in a negress; both had lived in the city for thirty years; neither had ever used corn meal as food. The etiological factors were difficult to explain: not all patients were subject to the same dietetic conditions, but all had some fundamental privation most probably. Bringing pellagra into the list of nutritional diseases, and Doctor Wood's careful work led in

that direction, gave reason to hope for its control. How might the sudden irruption of pellagra in the United States be accounted for? Was it present, but unrecognized formerly? The disease was undoubtedly on the increase.

Dr. Alfred F. Hess, of New York, was unable to discuss pellagra as a deficiency disease, but an observation in infantile scurvy might be of interest in this connection. Doctor Wood had found the corn germ curative for pellagra; he himself had found that the wheat germ alleviated scurvy; middlings had some, but less effect. Another experience indicated the diverse origins of deficiency diseases; beriberi and scurvy had some symptoms in common—tachycardia, nerve changes, etc. But yeast, which was specific for beriberi, had no effect in scurvy.

Dr. Nathan E. Brill, of New York, said his experience coincided with Doctor Sailer's. He had recently observed a man who had not been outside New York city in twelve years; he had a gastric ulcer for which a posterior gastroenterostomy was done. Later he contracted pellagra, but stated that he had never tasted corn meal in his life.

Dr. E. J. Wood, of Wilmington, N. C., said he had seen many pellagrins who had never eaten corn meal in their lives, but who, nevertheless, were relieved by feeding them corn chips. Wheat germ probably acted in the same way. The very extensive use of baking powder and soda in the South might be a factor in the pellagra problem; these ingredients in bread might liberate enough sodium carbonate to destroy the vitamines in the best of grain. It was a fact that the sudden appearance of pellagra in the South was coincident with the disappearance of the old fashioned water power grist mill.

Leucemia, Lymphosarcoma, and Hodgkin's Disease.—Dr. C. H. Bunting, of Madison, Wis., and Dr. J. L. Yates, of Milwaukee, had encountered difficulties in the differential diagnosis of leucemia, lymphosarcoma, and Hodgkin's disease since the report of the bacterial findings in Hodgkin's disease three years ago. They had in common: 1. A primary focus of infection; 2, progressive glandular enlargement; 3, a chronic course with late anemia and late fever; 4, eventual fatal termination; 5, early Hodgkin's blood picture or leucemic blood picture; 6, all yielded a diphtheroid organism. A new grouping of the types was suggested. The general drift was that the leucemic blood picture might appear in all the groups: Should they adhere to the classification of these diseases in three separate compartments; or should they be regarded as variations of one process associated with the diphtheroid organism? The speaker gave reasons for regarding this organism as etiological.

Dr. H. G. Wells, of Chicago, said that in studying mice in the course of his tumor work, a lymphatic condition, indistinguishable from leucemia in man, had been repeatedly observed. Nothing like lymphogranulomatosis or Hodgkin's disease had been found. Mice in which leucemia developed did not have tumors.

Dr. Theodore C. Janeway, of Baltimore, said that while they all recognized the value of Doctor Bunting's contributions to the blood pictures of the leucemias, he felt that their understanding of these conditions was not advanced by stating that a diphtheroid organism was always present, nor by explaining contradictory findings on the basis of technical errors. He cited studies made in Baltimore of all sorts of lymph nodes without finding diphtheroid organisms with any constancy.

Dr. Frank Billings, of Chicago, said that studies had also been made in Chicago of lymph nodes from Hodgkin's disease and other lymphatic diseases: in forty-odd cases the diphtheroid organism had been recovered from all except two. But the same organism had been found in goitres, in joints, in tuberculous glands, etc.; so that he was inclined to the belief that it was a parasitic organism accidentally present in pathological tissue. Animal experiments with the organism had not indicated specificity; and he did not believe it had any etiological relation to the lymphatic diseases.

Dr. C. H. Bunting, of Madison, Wis., said the time at his disposal was too short to give all the evidence upon which he based his belief in the specificity of the diphtheroid organism; these evidences were fully set forth in the paper. With regard to Doctor Wells's interesting remarks, there had been reason to suspect that in his own animal work he had run into a tumor-producing strain of organism. The animal experiments had been very strongly suggestive to him and his coworkers. He hoped that in time he might be able to straighten the whole matter out.

Polycythemia Treated with Radium.—Dr. Joseph Sailer, of Philadelphia, gave the history of a case of polycythemia in a woman. After exhausting the usual therapeutic measures, radium was carefully employed. The spleen was greatly reduced in size; after four months, the red cell count dropped from 7,621,000 to 5,674,000. Lately the subjective symptoms had disappeared, and the patient had become a fairly active woman. When the treatments were suspended, symptoms recurred.

Dr. Max Einhorn, of New York, said with regard to the therapeutics of polycythemia that he had seen a case of this condition a year ago in a man whose cells numbered 6,500,000; his principal symptom was dyspnea. He had sought to increase the fluids of the body and so dilute the blood by giving a quart and a half of milk daily. The symptoms were much improved by this simple measure.

Treatment of Pernicious Anemia by Transfusion and Splenectomy.—Dr. H. Z. Giffin, of Rochester, Minn., reviewed thirty-two cases of splenectomy for pernicious anemia. Nineteen of the patients were treated by transfusion and splenectomy, and thirteen by splenectomy alone. There were postoperative records from one month to three years, also statistics of definite postoperative occurrences, and the estimation of urobilinogen and urobilin in the duodenal contents (Schneider test) before and after splenectomy.

The Bile Content of the Blood in Pernicious Anemia.—Dr. M. A. Blankenhorn, of Cleveland, while investigating the nature of jaundice in pernicious anemia, observed that many patients, although distinctly jaundiced, showed no bile in the urine. The blood plasma, however, in every such case

showed a corresponding jaundice. These plasmas, when presenting a jaundice of a certain intensity, all gave a positive test for bilirubin. Urobilin was found in the plasma of none. There was often found a higher concentration of bilirubin in the plasma, coincident with the absence of bile in the urine, than was found in the plasma of patients with certain lesions of the liver which were always characterized by bile in the urine. Bile salts were found in the plasma in ten out of thirteen cases. The cases showing the highest concentration of bilirubin in the plasma were those with evidence of the most active blood destruction. The cases showing the highest concentration of salts were those in which nerve lesions predominated.

Dissociate Jaundice.—Dr. C. F. HOOVER and Dr. M. A. BLANKENHORN, of Cleveland, said that dissociated cholemia and dissociate choluria might be correlative in many cases, and not the consequence of dissociative biliary retention. Pigmental jaundice without bile salts was invariably hematogenous and never originated from dissociate hepatic retention of the bile pigments. Pigmental cholemia without bile salts was frequently a survival of complete biliary retention. Pigmental choluria without bile salts occurred only in hematogenous jaundice. Bile salts were not present in hematogenous cholemia. Bile salts unaccompanied by bile pigment might occur in the blood of primary anemia and lead poisoning. Bile salts unaccompanied by bile pigment might occur in the urine as a consequence of dissociated retention of bile salts in primary anemia and lead poisoning. Bile salts in the urine without bile pigment (with primary anemia and lead poisoning excepted) was always due to renal dissociation of complete cholemia on account of the absorption of bile pigment in the plasma and the escape of bile salts through the renal filter. The maximum cholemia (pigmental) without choluria, occurred in the jaundice of infections in which the pigment might be both hematogenic and hepatogenic. Obstructive jaundice yielded only moderate cholemia without choluria; choluria appeared when the cholemia became considerable. In hemolytic and infectious jaundice there might be pronounced cholemia without choluria.

Dr. L. G. ROWNTREE, of Minneapolis, emphasized the great value of Schneider's work. Bile in pernicious anemia was ordinarily very dark; it differed from the bile in other forms of anemia. Schneider was now finding the biliary changes typical of pernicious anemia in cases of atrophic cirrhosis of the liver. He would ask, Did Doctor Giffin's work include any cases of acute aplastic anemia?

Dr. G. H. WHIPPLE, of San Francisco, inquired if Doctor Blankenhorn had tested the blood plasma with Hilpert's test? This was a much more delicate test than those mentioned in the paper. In his own work he had found that the blood often yielded "half baked" pigments which might easily be mistaken for urobilogen. The observations of bile in the plasma with no bile in the urine had to be very carefully checked. If Doctor Blankenhorn had found a really satisfactory test for bile pigments, he was to be congratulated.

Dr. R. C. CABOT, of Boston, said that the age of splenectomized pernicious anemia patients had a potent influence on the outcome. Transfusion after splenectomy had a more lasting good effect than when done with spleen still in place. Had Doctor Giffin noticed any great tendency to thrombosis following splenectomy? So far as the usefulness of splenectomy in pernicious anemia was concerned, he expected to have his spleen removed whenever he acquired pernicious anemia.

Dr. M. A. BLANKENHORN, of Cleveland, said that there was no more delicate test for bile pigments than Gmelin's; all the others had been thoroughly tried and compared. He accepted Doctor Whipple's congratulations on the finding of a satisfactory test for bile pigments with the same reserve with which the congratulations were offered; those employed were the best that had been devised up to the present time.

Dr. C. F. HOOVER, of Cleveland, said that Doctor Blankenhorn had spoken of the use of Pettenkofer's test. This test was controlled by use of the spectroscope: in the presence of bile pigments there was a characteristic movement of absorption bands; no tests in the work reported had been accepted unless this movement of the absorption bands was noted.

(*To be continued.*)

Book Reviews

[*We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.*]

A Textbook of Practical Therapeutics, with Especial Reference to the Application of Remedial Measures to Disease and Their Employment Upon a Rational Basis. By HOBART AMORY HARE, M. D., B. Sc., Professor of Therapeutics, Materia Medica, and Diagnosis in the Jefferson Medical College of Philadelphia; Physician to the Jefferson Medical College Hospital; One Time Clinical Professor of Diseases of Children in the University of Pennsylvania. Sixteenth Edition, Enlarged, Thoroughly Revised, and Largely Rewritten. Illustrated with 149 Engravings and 7 Plates. Philadelphia and New York: Lea & Febiger, 1916. Pp. vi-1009. (Price, $4.75 net.)

No clinician can afford to neglect therapeutics. With the great advances in scientific progress the tendency has been to concentrate attention upon diagnosis and laboratory investigation, and to neglect and disparage therapeutics. No physician, however, is doing his best for the patient unless he is constantly endeavoring to perfect his therapeutical knowledge and skill. A good understanding of therapeutical pinciples, and a thorough familiarity with the use of drugs should always be desired and cultivated. Such attributes characterize Hare's *Textbook of Practical Therapeutics.* The subject matter is admirably arranged, with a clear and concise exposition that enhances its value as a ready reference book on general therapeutics. By way of introduction there is a brief discussion of general therapeutical considerations, the preparation and administration of drugs, and prescription writing. In the pharmaceutical section each drug is described in detail, together with its physiological action, its therapeutical uses, and its incompatibilities and administration. The latter part of the book gives brief considerations of remedial measures other than drugs, including transfusion, vaccines, and foods suitable for the sick. At the end the author describes and discusses the treatment of the various common diseases. There is an excellent index of drugs, and of diseases with the remedies. We regret that no mention is made of psychotherapeutics, and wish that the modern methods of treating syphilis had been given in more detail. For a practical reference book, we can confidently recommend it with the assurance that the student or practitioner will find in it many practical suggestions for everyday use.

Studies in Blood Pressure. Physiological and Clinical. By GEORGE OLIVER, M.D. (Lond.), F.R.C.P. Edited by W. D. HALLIBURTON, M.D., F.R.S. Third Edition. New York: Paul B. Hoeber, 1916. Pp. xxiii-240. (Price, $3.)

The appearance of the third edition of Oliver's *Studies in Blood Pressure* suggests the thought that it would be a good thing if more medical men who have opportunities would combine clinical and experimental study. Oliver was able to do this during the latter part of his career by a season spent at Harrogate with clinical opportunities in cardiovascular disease among well to do people in whom it is more frequent, except in its cruder forms, than among the poor. The remainder of the year he spent in the university in laboratory investigation. This combination of cure resort practice with university work has produced some of the best authorities in medicine and may be an answer to the problem of coordinating the laboratory worker and the practitioner. The book, as its name implies, is a series of studies which have been printed together rather than a systematic treatise. In it have been assembled by quotation the opinions of a great many authors. It will prove most suggestive to those who seek to solve the problems of blood pressure.

Lectures on Dietetics. By MAX EINHORN, Professor of Medicine at the New York Post-Graduate Medical School and Hospital, and Visiting Physician to the German Hospital, New York. New York: Paul B. Hoeber, 1914. Pp. 156. (Price, $1.)

This little book, which includes eight of the author's lectures at the New York Post-Graduate Medical School, has the merit of conveying to the average medical reader precisely what he wants without fatiguing him with technicalities which befog the intelligence and prevent the retention of essential facts. After reviewing the general principles of diet and nutrition in a manner most lucid for so abstruse a subject, the author outlines the principles of food digestibility in health, and in acute, prolonged, and chronic diseases. Special attention is given to the dietetics of chronic affections of the digestive tract, chronic diarrhea, and diabetes mellitus, in all of which diseases dietetic treatment plays the leading role. The various diet régimes, superalimentation, Banting's, vegetarian, Bulkley's, and others are described succinctly, though sufficiently for practical purposes. On the whole, this little volume is entitled to commendation.

Modern Medicine. Its Theory and Practice in Original Contributions by American and Foreign Authors. Edited by SIR WILLIAM OSLER, Bart., M.D., F.R.S., Regius Professor of Medicine in Oxford University, England; Honorary Professor of Medicine in the Johns Hopkins University, Baltimore, etc., and THOMAS MCCRAE, M.D., Professor of Medicine in the Jefferson Medical College, Philadelphia; Fellow of the Royal College of Physicians, London; Formerly Associate Professor of Medicine, The John Hopkins University. Volume V. Diseases of the Nervous System—Diseases of the Locomotor System. Second Edition, Thoroughly Revised. Illustrated. Philadelphia and New York: Lea & Febiger, 1915. Pp. ix-1002. (Price, $5.)

If any comparison between the various volumes of this excellent work is warranted, the last should be considered the best of the series, although it perpetuates a deficiency for which the previous volumes have been notable, that of affording but meagre assistance in the therapeutics of the many diseases reviewed. The various collaborators would seem in this particular, to have become imbued with Osler's therapeutic pessimism and deemed it necessary to assume his attitude on the subject. Indeed, hardly three per cent. of the eight hundred and odd pages on nervous diseases are devoted to treatment. Of course, in calling attention to this defect, a serious one from the viewpoint of the practitioner, who needs carefully prepared ammunition in his strife against disease, we are reminded of a paper published some years ago, in which a neurologist expressed the view that it was hardly necessary to diagnosticate nervous diseases, since their treatment was of no avail! Yet there are many details in the treatment of neurological conditions which increase greatly the value of professional efforts, and it is hoped that the next edition will show a marked improvement in this direction.

In every other respect the work is of inestimable value. The field covered is most comprehensive, and each article is replete with clinical data calculated to convey a correct interpretation of the disease from the standpoints mainly of diagnosis and pathology. The diseases of the osseous and muscular systems close the work. Worthy of special note is the article on arthritis deformans, which includes all forms of arthritis, by one of the editors, Doctor McCrea. It is a model in completeness and is so written as to be within the reach of all.

Nouvelles Méthodes de Séro-Diagnostic. Syphilis, réaction de Wassermann, méthodes de simplifications, valeur pratique de la méthode, luétine, réaction de l'or colloïdal, réfractométrie, sérodiagnostic de la grossesse, réaction d'Abderhalden, mycoses, kyste hydatique, lepre, mycosis fongoïde, maladies infectieuses. Par ED. JOLTRAIN Ancien interne des Hôpitaux. Préface du Professeur GAUCHER. Quatrième Édition revue et augmentée. Avec 7 planches hors texte. Paris: A. Maloine et Fils, 1916. Pp. viii-413.

In this excellent manual are taken up in detail, after a preliminary section on the theory of immunity, agglutination, hemolytic serums, the reactions of fixation, and complement deviation, etc., the methods of serum diagnosis of syphilis, mycoses (including sporotrichosis and actinomycosis), hydatid cyst, leprosy, and mycosis fungoides, the reaction of fixation in various infectious diseases, the newer conceptions of immunity as illustrated in hemoclastic paroxysms, and the Abderhalden reaction, and some secondary methods of serum diagnosis, such as opsonin estimation, estimation of antitryptic power, and the miostagmin reaction. The Wassermann reaction is explained with special care, and several colored plates showing the color changes in the several test tubes employed in the test are presented. Gaucher, in an introduction to the book, directs special attention to the modified Wassermann reaction worked out by Desmoulière in his laboratory. By using a special antigen, prepared by adding cholesterin to an alcoholic maceration of powdered liver tissue extracted with ether, a precise and sensitive test is obtained. The present is the fourth edition of the book, and was finished in an ambulance at the front. A copious bibliography concludes the work.

Interclinical Notes

The *Survey* for November 11th tells of a sickness census taken on October 26th in Milwaukee, in order to ascertain what proportion of the people in the city are sick at a given time, whether or not they have proper medical care, the number of sick who are wage earners, and the extent to which these sick wage earners receive some sort of sick benefit or insurance.

* * *

The explanation of the recent Presidential election, which did not come out at all as arranged by Mr. George Harvey, is given in the December *North American Review;* it closes with some challenging italics: "Clearly, what the whole country needs, from Maine to California, from the lakes to the gulf, is a course in patriotism." L. Ames Brown discusses prohibition as a Federal political issue in this number of the *Review;* it seems to us that if prohibition becomes a national law, we shall be in the last abyss of humbug, unless, indeed, what seems improbable, the present scientific view of alcohol becomes the popular one.

* * *

The Relation of Malaria to Crop Production, by D. L. Van Dine, is the first title to strike the eye on taking up the *Scientific Monthly* for November; the physician's eye, we mean. Another attractive title is Stephen Hales, the Pioneer in the Hygiene of Ventilation, by Dr. D. Fraser Harris. Eugenics, by Professor Franz Boas, is provocative of curiosity, and the Psychology of Wish Fulfilment, by Professor John B. Watson, will introduce to some of our chaste friends the theories of that dreadful person, Freud. We do not think there is a single naughty word in this paper. The writer makes the interesting suggestion that men high up in the business world, the diplomatic service, and in government positions generally, who often have enormous responsibilities placed upon them, should be relatively free from strong inward conflicts and repressions, and therefore should be selected only after careful psychanalysis.

Meetings of Local Medical Societies

Monday, *December 11th.*—New York Ophthalmological Society; Society of Medical Jurisprudence, New York (annual); Roswell Park Medical Club, Buffalo; Williamsburg Medical Society, Brooklyn (annual); New Rochelle Medical Society.

Tuesday, *December 12th.*—New York Academy of Medicine (Section in Neurology and Psychiatry); Medical Society of the County of Schenectady (annual); Medical Society of the County of Rensselaer (annual); Buffalo Academy of Medicine; New York Obstetrical Society; Onondaga Medical Society (annual); Medical Society of the County of Chautauqua (annual).

Wednesday, *December 13th.*—New York Pathological Society; New York Surgical Society; Alumni Association of the Norwegian Hospital, Brooklyn (annual); Schenectady Academy of Medicine; Medical Society of the Borough of the Bronx; Richmond County Medical Society (annual); Rochester Academy of Medicine; Medical Society of the County of Montgomery (annual); Brooklyn Medical Association.

Thursday, *December 14th.*—New York Academy of Medicine (Section in Pediatrics); Gloversville and Johnstown Medical Association; Physicians' Club of Middletown; West Side, New York, Clinical Society (annual); Brooklyn Pathological Society; Blackwell Medical Society of Rochester; Jenkins Medical Society, Yonkers; Society of Sanitary and Moral Prophylaxis, New York; Buffalo Ophthalmological Club; Jamestown Medical Society; Society of Physicians of Village of Canandaigua.

Friday, *December 15th.*—New York Academy of Medicine (Section in Orthopedic Surgery); Clinical Society of the New York Post-Graduate Medical School and Hospital (annual); New York Microscopical Society; Mount Vernon Medical Society; Saratoga Springs Medical Society.

Official News

United States Public Health Service:

Official list of changes in the stations and duties of commissioned and other officers of the United States Public Health Service for the seven days ending November 29, 1916:

Applewhite, C. C., Assistant Epidemiologist. Directed to proceed to Hillsboro, Texas, for duty in studies of rural sanitation in Hills County.

Bote, G. S., Field Investigator. Directed to proceed to Hillsboro, Texas, for duty in studies of rural sanitation in Hills County.

Irwin, F., Senior Surgeon. Directed to proceed to Reedy Island, Del., Quarantine Station on business relative to the construction of barracks.

Lavinder, C. H., Surgeon. Detailed to attend a meeting of the Philadelphia College of Physicians, December 6, 1916, to participate in a symposium on poliomyelitis.

McDevitt, C. J., Assistant Surgeon. Detached from Coast Guard cutter *Manning* and ordered to proceed to San Francisco, Cal., Quarantine for duty.

Saunders, Samuel, Field Investigator. Directed to proceed to Hillsboro, Texas, for duty in studies of rural sanitation in Hill County.

Schereschewsky, J. W., Surgeon. Detailed to attend a conference on social insurance at the U. S. Department of Labor, Washington, D. C., December 5th to 9th.

Scott, E. W., Assistant Surgeon. Granted one month's leave of absence from December 12, 1916.

Sharp, W. K., Jr., Field Investigator. Directed to proceed to Hillsboro, Texas, for duty in studies of rural sanitation in Hill County.

Stiles, C. W., Professor. Directed to stop en route under Bureau orders of November 7th, at Greensboro, N. C., to deliver an address at a meeting of the Eighth District Medical Society, December 5th.

Sydenstricker, E. L., Public Health Statistician. Detailed to attend a conference at the U. S. Department of Labor, Washington, D. C., December 5th to 9th, and participate in discussions on health insurance.

Witte, W. C., Assistant Surgeon. Directed to proceed to Hillsboro, Texas, for the purpose of conducting studies of rural sanitation in Hill County.

Boards Convened.

Board of which Assistant Surgeon General W. G. Stimpson is chairman, convened by Bureau letter dated September 9, 1916, reconvened to prepare questions and conduct the examination of applicants for appointment as assistant surgeon at the Bureau, Washington, D. C., Monday, December 4, 1916.

Boards of commissioned officers convened for the examination of applicants for appointment as assistant surgeon, Monday, December 4, 1916, as follows: Seattle, Wash., Surgeon B. J. Lloyd, chairman; Passed Assistant Surgeon E. Krulish, recorder; Cincinnati, Ohio, Passed Assistant Surgeon W. H. Frost, chairman; Passed Assistant Surgeon Paul Preble, recorder.

Births, Marriages, and Deaths

Married.

Hauser-Bodine.—In Danville, Pa., on Friday, September 15th, Dr. Raymond Jack Hauser and Miss Ethel Bodine.

Died.

Benjamin.—In Riverhead, N. Y., on Sunday, November 26th, Dr. John Halsey Benjamin, aged sixty-two years.

Covert.—In Perrysville, Ohio, on Wednesday, November 8th, Dr. Samuel J. Covert, aged sixty-six years.

Clark.—In Cleveland, Ohio, on Thursday, November 23d, Dr. Frank S. Clark, aged fifty-two years.

Garrett.—In Hope, Ark., on Friday, November 17th, Dr. Hosea J. F. Garrett, aged fifty-five years.

Green.—In Long Branch, N. J., on Friday, November 24th, Dr. James O. Green, aged seventy-six years.

Horsley.—In West Point, Ga., on Friday, November 17th, Dr. Joseph Stafford Horsley, Sr., aged seventy-four years.

Jones.—In San Francisco, Cal., on Monday, November 27th, Dr. Philip Mills Jones, aged forty-five years.

Kane.—In Minooka, Pa., on Monday, November 20th, Dr. John Frank Kane, aged thirty-two years.

Keany.—In Boston, Mass., on Thursday, November 23rd, Dr. Francis Joseph Keany, aged fifty years.

Lynde.—In Buffalo, N. Y., on Tuesday, November 21st, Dr. Uri Colvin Lynde, aged eighty-three years.

McGranahan.—In Youngstown, Ohio, on Saturday, November 18th, Dr. William H. McGranahan, aged sixty-two years.

Mason.—In New York, on Tuesday, November 21st, Dr. John James Mason, of Newport, R. I.

O'Hare.—In Rochester, N. Y., on Tuesday, November 21st, Dr. Thomas Augustine O'Hare, aged sixty-eight years.

Parrish.—In Memphis, Mo., on Wednesday, November 22nd, Dr. John E. Parrish, aged seventy-six years.

Penn.—In Omaha, Neb., on Saturday, November 11th, Dr. John H. Penn, of Ravenna, aged fifty-five years.

Peters.—In Walden, N. Y., on Thursday, November 23d, Dr. Jacob Brill Peters, aged sixty-three years.

Pitcher.—In Detroit, Mich., on Sunday, November 19th, Dr. Sheldon Pitcher, aged fifty-four years.

Ramsay.—In Newport, R. I., on Monday, November 27th, Dr. M. George Douglas Ramsay, aged forty-seven years.

Robbins.—In Trenton, N. J., on Thursday, November 30th, Dr George R. Robbins, aged seventy years.

Sanborn.—In Spencer, Mass., on Tuesday, November 21st, Dr. Frederick James Sanborn, aged fifty-five years.

Shepardson.—In Springfield, Mass., on Thursday, November 23rd, Dr. Oscar Jerome Shepardson, of Chester, aged sixty-four years.

Walker.—In Thomaston, Me., on Wednesday, November 22d, Dr. John E. Walker, aged fifty-eight years.

Whittleton.—In Webster, N. Y., on Monday, November 20th, Dr. Ellery J. Whittleton, aged fifty-seven years.

Woods—In Brookline, Mass., on Thursday, November 16th, Dr. Jonathan Henry Woods, aged sixty-six years.

Young.—In Johnstown, N. Y., on Sunday, November 26th, Dr. James Kilbourne Young, aged sixty-eight years.

MEDICAL FEES AMONG PRIMITIVE MAN.

Their Collection by Physicians,

BY JONATHAN WRIGHT, M. D.,

Pleasantville, N. Y.

The question of what is due the doctor comes up every day, at least the first day of every month, and it often gives rise in the grave judicial councils of innumerable medical societies, to many wrathful or tearful remarks. I cannot see why this matter should not be investigated in the light which the history of the evolution of medicine can cast upon it. I have selected from a pile of manuscript certain indications of the way the primitive physician treats the problem, which I hope will not be devoid of interest to his cultured brother. Such information may be vastly extended, but, at the cost of its quite fragmentary nature, I am compelled here to economize space. In what follows there will be found illustrated about all the ways in which physicians are or have been, in historical time, paid for their services, not forgetting the imponderables of life. At least, all the ways that occur to me at the moment of writing, I have sought to illustrate in the accounts of medical practice observed among primitive men. Doubtless, if any principle of recompense has been neglected by an oversight, its exemplification also could be found among the records. It will be noted that, through contingent fees, the principle of accountability for mistakes was much more prominent in primitive tribes than in the cultured state, but scarcely more so than appears in the Assyrian code of Hammurabi. Indeed, this is a very vital point today, not only in practical ethics, but in the administration of justice concerned with the modern relations of physicians to the public. It excited the virulent invectives of Pliny the elder and of Petrarch and the witty thrusts of Molière's rapier. *Soit qu'on fasse bien, ou soit qu'on fasse mal, on est toujours payé de même sorte,* exclaims Sganarelle. A shoemaker has to pay for the leather he spoils, but the doctor's slips, says our critic, are unpunished—ascribed to the will of God. We are still attempting to meet this criticism, which for thousands of years has rolled down the ages, by raising the standard of medical education in the foolish hope that man can be brought to that point of perfection by virtue of which he can escape error. We are liable to remain the butts for mocking wits and the victims of vicious legislation, if nothing but that is to be done. Much more efficacious is it to lay aside the arrogance of pedantry, and the bluffing tactics with which attempts are made to patch out the robe which covers our own ignorance. This is what we may lay to our own hearts before we can hope that the better educated public, recognizing that the doctor is made, like themselves, of common clay, and liable to err even in the tragic circumstances of life and death, will be more disposed to cast the mantle of charity over the manifold sins and shortcomings of their medical brothers. Not only contingent fees, but fees in advance, State subvention, that is, tribal support for the doctor, special fees for special work, mock modesty in exacting payment for that which God has brought about—these and many other aspects of the returns the doctor expects from the social organization for his services are to be seen in embryo or in full bloom among the wild tribes of men.

The rewards a man reaps from the practice of his profession, we all acknowledge, are not to be measured in dollars and cents; the interest we feel in it as a science, the joy of work, the avoidance of idleness, but above all things which figure in the platform inducements held out to the young student, is that of ministering to the Lord's poor. This, it is true, has rather an antiquated look. It did very well, perhaps still does, for those intending to go into missionary medicine, but perhaps it is just as well to alter the phrase a little in order to give it a quite modern turn and say: It is a noble altruistic calling to benefit our fellowmen. We remember Miss Kingsley's frank avowal that the savage in his wilds knows not these things. So perhaps a little analysis of what we ourselves mean is desirable. Indeed, it has seemed to me the chief difficulty in getting at the back of the mind of primitive man lies in our not getting first to the back of that of his civilized offspring. Every age has its ideals, and he who clings the closest to those of his own day is apt to rank in the opinions of his fellowmen where his ambition would place him—not always first in peace, not always first in war, but always first in the hearts of his countrymen. The social tie that binds man to man is at first weak. It may seem strong as between small units, the family or the clan, but the periphery of altruistic devotion is small and enlarges slowly. It does not fire the enthusiasm of the savage to see his doctor staunching the wounds of a strange man, much less of an enemy. In a state of society where a man feels it absurd not to sell his

sister's children when he is hungry, we cannot expect much enthusiasm for altruism. So these rewards are not apparently to any marked degree valued by those members of our profession who practised among the cave men. Safety first—sought through fear—then admiration by the weak for the power secured through fear, the favor of the gods, or in any other way by the sorcerer—it is quite a long way we have traveled up to the 1916 ideals of our "noble profession"—and at each mile post, be sure the imponderable fees, those not beneath the cow's skin nor in the cowskin pouch, were always at hand, but always a little different—thank Heaven. So in speaking of fees, let us not forget those imponderables for which man has fought and cheated and killed and drugged all the way along the road. Unless we keep these in mind we shall understand the motives of primitive man as little as our own. Safety first, and then the admiring glances of men and women, acquired by poison if practicable, but when that is crowded out owing to increasing prejudice—by altruism. After this somewhat disagreeable discourse it will not be necessary to obtrude the instincts of vanity, ambition, pride, or the "pride which apes humility"—or altruism. Man's passions, instincts, emotions have remained the same from his home in the cave to his house in the choicest of modern situations.

We do not know exactly how prehistoric man collected his fees, but from the study of modern primitive races we may draw inferences in regard to him which we have every reason to believe are warranted. In Northwest America the Ten'a medicine man is rich because his services, when he is summoned or when they are accepted, though uncalled for, are generously remunerated, for he is listened to on account of the superior knowledge imparted to him by the spirits. He is feared on account of his power to do evil—to cause the death of a person, to render him unsuccessful in the hunt by driving away the game from his path, to cause the loss of his property, of his strength, of his health, of his faculties (1). We see the scope of the doctor's power was wide and we readily understand the source of his wealth, but even in the narrower fields of legitimate medicine he had an entrenched position; we soon perceive, however, that he had his troubles. Among them contingent fees were by no means the most serious.

Primitive man had occasionally to bid high for the favor of a diagnosis or a cure. Among the Minnesota Indians Mr. Nicollet (2) heard the voice of the turtle speaking through the medicine man, "Well, old miser, you should have sugar, too, only speak!" begging the spirit for a diagnosis, and "when the case is grave the father or the mother, in consulting about a child, or a relation, will go so far in their offerings as to say, 'if you cure him or her, I will give you my daughter.'" With the California Indians (3) "if a patient dies, then the medicine man is forced to return his fee; and if he refuses to attend any one and the person dies, then he is forced to pay to the relatives a sum equal to that which was tendered to him as a fee in the beginning of the affair." With the Koniagas, "if the patient recovers, the physician is paid, otherwise he receives nothing." In British North America the doctor of the Carriers "before commencing his operations in the sick room, must receive a fee, which, if his efforts prove unsuccessful, he is obliged to restore." This was very largely true of the North American Indians generally. The modern surgeon's advance fee is no innovation in America. With the Nootkas he is not paid if he fails, "but if successful, does not fail to make a large demand." Among the Haida (4), "in cases of serious illness chief reliance was . . . . placed upon . . . the medicine men, who were paid liberally, if the patient lived, or if he died, were compelled to restore the goods they had previously received on account." In India, among the Naga tribes of Manipur (5) when they are sick "all their goods and chattels may be expended unavailingly, and when nothing is left for the inexorable gods, I have seen their wives and children sold as slaves to provide the means of propitiating them. In sickness, therefore, the speedy recovery or the speedy death of the patient is desirable."

The Zulu medicine man's *ipsissima verba* (translated), are, when invoking the spirits: "'Here is a bullock I may gain, ye people of ours. I dig up this medicine, trusting in you, that you will give it power to take away the disease from the sick man, that I may become celebrated among the nations, as a great doctor, by your power, ye people of ours.' He digs up the medicine, then, with a pure heart, expecting the man to get well. He obtained many cattle from people for doctoring their cattle. He became a celebrated doctor. If the cattle got well he had one given him" (6).

The poor in our dispensaries we do not expect to give us as much trouble, nor do we sugar coat their pills quite so thick as we do those for our office patients. In North America, "among the Ohyahts, a few years ago there was a young woman, deformed and of diminutive stature, who had a high medical reputation. A native presented his leg to her, which she grasped at the knee, and rubbed, as would a Malvern doctor. On its being remarked that she did not cry nor groan, as usual with native practitioners, the patient explained aside that she was quite skillful in her work, but that if in his case she cried or groaned during the operation of rubbing, her charge would be a blanket, instead of a fathom of small beads, and he could not at that time afford the blanket (7). This sort of privilege for the rich is much more marked in Thibet. Contract medicine, with regular days for salaries, though these apparently varied in kind, is a feature among some African tribes, and we see its faults—tips. "Celebrating the victory over disease, the day of *hondlola* is considered as a fête day. Beer is prepared as a mark of gratitude to the doctor and 'to rejoice his heart.' It is also the day of reckoning: the physician must be paid: this personage has not, however, waited until now to ask for a 'refresher.' From the commencement of the case, it has been necessary to *pfula hwama*, that is to say, to lift the cover of the medicine wallet by means of a sixpence or a shilling. At times he has been very anxious to change the medicine, in order to produce a greater effect; on such occasions he has been presented with a chicken as an encouragement; but on the day of the *hondlola*, when his skill is joyfully attested, and the cure an accomplished fact, accounts must be definitely

settled with the *nanga,* who will henceforth discontinue his visits"(8). Still more primitive, but practically the same custom, is found in Australia(9). "It goes without saying that the wizards and doctors in all these tribes did not exercise their power gratis. Presents were given them by people who had benefited by their art, and also by people who feared lest they should suffer from it. They received presents of weapons, rugs, implements—in fact, of all those things which are of value to the aborigines, not forgetting a share of the game caught. Especially did they reap a harvest at the great gatherings. The Bunan gatherings of the Coast Murring may be taken as an example. Before the people separated to return home, a sort of fair or market was held, to which people brought the weapons, rugs, implements, etc., which they had brought with them for the purpose. From these 'fairs' the gommeras went away loaded with gifts."

As an example of doctors paid by the State, Bartels (10) says that among these Australians there seem to be no fees from the patients, but the doctors are supported by the contributions in services and food, by the other members. Among the Australians they may also receive in addition gifts from the patients, which for the most part are paid only when there is a successful issue to the illness. In Central America(11), it seems, the natives are not only more altruistic but more tolerant. It is well to note these variations, for did they not occur social evolution would have no material for selection. "No reward of any kind is given, or expected, nor is any blame attached in case of nonsuccess, the latter being attributed to the malignant action of superior magic on the part of some hostile spirit or individual." In Malaysia the doctor's superior freedom from the consequences of his ignorance or maladroitness does not interfere with his fees, though success increases them. Among the Dyaks of Borneo, "whether the patient lives or dies, the *manang* is rewarded for his trouble. He makes sure of this before he undertakes a case, as he is put to a considerable inconvenience by being fetched away from his home and his own work. He takes up his abode with the patient, and has his meals with the family, and in other ways makes himself at home. If a cure be effected, he receives a present in addition to his regular fee (12).

In some places in West Africa (13) the doctor takes the matter into his own hands as to whether the patient is benefited or not, though if he dies I suppose there are ways of explaining it at least. "'If it should be a case of undissembled sickness, and the patient becomes worse by this unnatural treatment, the witch doctor is removed, and the ceremonies are suspended, and it is concluded that it was not a real possession, but something else. The priests have certain tests by which it is known when the patient is healed, and the whole transaction is wound up when the fees are paid. In all cases of this kind it is impossible to say whether the devil has really been cast out or merely a better understanding arrived at between him and the person he has been tormenting. The individual is required to build a little house or temple for the spirit near his own, to take occasional offerings to him, and pay all due respect to his character, or to be subject to renewed assaults at any time.'" Abbé Proyart, with that broadmindedness which has always distinguished the French, even ecclesiastics, speaks with respect of the natives of Loango, at the early date at which he lived among them. He described nothing approaching the contingent fee. "As soon as the patient is dead or when he is cured, his relatives take up a collection for the benefit of the physician who has treated him through his illness. When they go to the missionaries for contributions, they ask them ordinarily for European brandy, telling them that that is the thing which is most pleasing to the doctor." Contingent fees we often note, but in the following quotation a new item is added to the bill, which is a compliment to the audacity and the resourcefulness of the primitive medicine man. It far surpasses adding a cipher because a man is rich. In the Aaru Islands (14) the evil results are sometimes excused by the attending physician with the assertion that the patient's ancestors were in debt to the doctor's ancestors. This debt is collected by the doctor three or fourfold.

For deprecating modesty, yet with an eye to the main chance, the following may be commended: "Having now described the general principles and manner of treatment employed by the African practitioners, it is proper in the next place to say something of the fees which they receive for their services. Being generally very modest, they do not take all of the credit to themselves, as doctors elsewhere do, for their wonderful works. They frankly admit that they are aided by certain powerful spirits that reveal valuable secrets. In many cases the practitioners make no charge at all for their own services, requiring only that the patient pay a fee to the cooperating spirit. For example, in the Cape Coast district, a certain doctor, in case of sickness, orders his patients to bury in the ground a few bottles of rum as a suitable recognition of the services of the spirit that has been brought into consultation" (15). This reminds us of the nonmercenary nature of practice in some countries where the gold piece is to be put carelessly on the mantel or table without the absorbed scientist seeing it. The doctress in the wilds of the Argentine (16) wished some cocoa buried in the ground for the spirit of disease she was contending with. "If I had done so," says the author, probably acquainted with disinterested physicians across the water, "I am quite sure that Petrona would have returned to the spring upon the following day, in order to take possession of the cocoa which we were to bury there." In Sinaugolo (17), where there is also a prejudice against abortionists, the lady who mutters incantations, with other procedures more practical, to drive the fetus from the uterus, is shy about fees. The patient "in paying, passes the fee behind her own back to the operator without looking around, and she is asked not to mention her name or see her again."

In the island of Nias, to keep off a dreaded epidemic, we find a practice of paying the doctors, somewhat akin to burying the rum in a place familiar to the African doctor who loves it. Money is collected and tied "in a bundle, and the priest holds the bundle up toward the sky and down toward the earth to satisfy the god of the upper and the god of the nether world that justice has now been done.

After that he either flings the bag of money into the river or buries it in the ground beside the idol. In the latter case the money naturally disappears, and the people explain its disappearance by saying that the evil spirit has come and fetched it" (18).

In relating with admiration the story of the conquest of Mexico, an old Spanish chronicler becomes reminiscent of practices at home which he has perhaps heard charged against our maligned "noble profession." The surgeons who were placed over the Aztecs in the civilization which the Spaniard destroyed "were so far better than those in Europe that they did not protract the cure in order to increase the pay" (19). We have an example among the modern Egyptians (20) which I relate here, but whose "civilized" origin I suspect, which shows how a bloated capitalist increases his hoards by exploiting secret remedies. "A rich man will sometimes buy a powerful fetish as a speculation, and make a good profit by hiring it out for a fee, and the poorer man will pay the fee, hoping to reap good results to his bodily health or to his prosperity by having the undivided interest of the fetish at his service." Something of the kind is related of some of the North American Indians, who retain as private capital in the family the secrets of medicine handed down to them by a celebrated medical ancestor.

In Tonquin (21), "when a rich man is ill, it is customary to propose a reward to whoever cures him; doctors and surgeons crowd around him; each in his turn gives him medicines, which are immediately paid for; and the reward is given to him whose medicine has been found to have operated a considerable alteration in the patient. They often succeed. What is most surprising is, that these multiplied medicines do not increase or fix the disorder; they cannot be dangerous, and their composition must be very simple. The doctor to whom they attribute the cure acquires great reputation; and yet those of the same profession who have been consulted . . . entertain no jealousy, . . ." which is more surprising still. In another one of the accounts in Pinkerton's *Voyages* (22), Bosman, describing the customs of the coast of Guinea, speaks of a method of charges scarcely more consonant with the most approved modern system of fees, and he does it with much uncharitable reviling customary to observers in the early days of sociological investigation, and "civilized" sects do not escape his criticism. "In sickness (in which they agree with all the rest of the world), they first have recourse to remedies; however, not thinking them sufficient alone to preserve life and restore health, they apply their false and superstitious religious worship, as more effectual to those ends; and what contributes to the promotion of this custom, is, that he who here acts the part of a doctor, is also a feticheer or priest, who consequently does not find it very difficult to persuade the patient's relations that he cannot be recovered without some offerings made to the false god in order to appease him; and they being strongly bent to superstition, and immediately ready to follow the priest's advice, accordingly desire him to inquire of their god what he would please to have. The priest, to be sure, is not negligent in this affair, where the profit accrues to him, but as soon as possible puts his cheats in practice; and after his pretended inquiry, he informs them that they must offer a sheep, hog, cock, dog, cat, or whatever he likes best; which sometimes may be gold, cloth, drink, and other such like good things beside, which are always proportioned to the ability of the person to be served; for that alters the measure of these cheats, who always consider whether the man be in condition to bear this charge; and herein they are indeed to be preferred to some Romish priests, whose undistinguishing exorbitant price of soul masses ruins several families."

As to the connection here intimated between the reward of the doctor and the fee of the priest, we may cite a remark from another author (23) of the same period which illustrates the blending of sacrifice to the gods and the doctor's fee. "In the kingdom of Achem, the priests called Raulins, are called in to the sick. They blow at them, at the same time pronouncing some mysterious words. They offer up to the god of the four winds a sacrifice of fowls, hogs, and the fattest animals, which must be repeated four times, unless the patient dies or recovers before that time. The Raulins feast on the food thus offered to their gods." It may be thought difficult to find a counterpart to this sort of remuneration in modern life. The same principles are brought into play when the "grateful patient" is invited to donate to the winning doctor's hospital, with which much of his material interests are associated.

It will be noted in the account of the way the Zulu collects bad debts that he depends on his standing well with a Higher Power for doing so. It being gods or demons who send as well as cure disease, their minister among mortals takes advantage of the disease producing powers of his master to get his pay for having exercised the disease curing powers which have been delegated to him by virtue of his ministry. In the absence of a legal collecting agency whose advertisements reach us through the mails this is not a bad substitute. In Africa, it is reported, the Zulu doctor needs a helper to detect the dishonest practices of his patients, preparing to cheat him of his contingent fees. In the words of a native, "When he has applied his medicines, the people try to eat him up by craft, and say, 'Let us tell him that I took his medicine, but gained no relief. It was as though I had taken nothing but corn.' For it is common among black men to conceal the power of medicines; they are but few who praise them. In consequence of this craft there came to be appointed secret spies. The doctor says to a man, 'So-and-So, do you go and listen for me. There is my medicine. I know that the people will conceal its efficacy, and say it was useless, for they are slow in giving me a bullock. I therefore appoint you to look out for me.' So then, when he has treated the patient, he waits to hear what happens, that he may know how he is. And then he hears him say, 'O, Son of So-and-So, I am still ill; as yet I am in pain all over; and as to that medicine of yours, it was as if I had only eaten corn.' So the owner of the medicine wonders, who understands its action in the human body, when he hears the man denying that it ever brought anything away, saying, 'No, there came away nothing but water.'

But his spy tells him that his medicine worked well in the man; that the people deceive him, and the man now goes to wedding dances and to beer drinkings; that he is quite well. But it is hard for him to give a bullock; he makes more of the disease which remains than of the health which has been restored." The sequel reads: "At length the doctor says, 'So-and-So, since you refuse to give me a bullock, I shall now remember the holes where I dug up the medicine which has cured you; and cry there. Something will happen to you, if you eat my bullock deceitfully. Do not say I am a sorcerer. Keep the bullock. I no longer wish to have it.' If he is really deceiving him, he refuses, saying, 'O, Son of So-and-So, for my part I do not say the disease has beaten you; I say you are my doctor, although I took your medicine without feeling any effects from it; yet it feels as if my body was about to be that of a man, if you persevere in getting medicines for me. I am your bullock. How do you think, if I get well, I can hide myself? Do not talk about crying at the holes where you dug up the medicines. You will kill me if you do so. Just doctor me. Your bullock is ready for you.' If he does not agree with him, the doctor awakes in the morning with his heart much pained because he hears from witnesses that he has really helped the man; but he will not allow that he has been helped. So he goes to the holes where he dug up the medicines, and scrapes away the earth and sheds tears, and tells the Amatongo (the spirit of medicine to whom the bullock is supposed really to belong) of his trouble, saying, 'Why are you eaten up by a man that I have cured? Let the truth appear. Let not my bullock be eaten by a living man; let the power of my medicines be evident, and not be a mere vain thing. I tell you the medicines were yours.' I cured him by your power. Is it pleasant to have your cattle eaten? He says this weeping. For it is said if the holes where the medicines were dug up are opened, and the doctor weeps there, the man will be ill and die, if he has really concealed the power of the medicines. Thus it is. With us it is a fearful thing that the doctor should go to the holes to cry; and it is said if he does so he calls down death on the patient. This, then, is what is meant by crying at the holes."

We may know more of etiology and pathology and therapeutics, but down in Zululand and in many another heathen land the natives could give the wisest of us much useful information about human nature. They may be given to fleshly lusts and they may go around naked, but these so called children of nature seem not infrequently to be clothed in guile.

ANORECTAL INJURIES.*

By Samuel Goodwin Gant, M. D., LL. D.,
New York,

Professor of Diseases of the Colon, Sigmoid Flexure, Rectum, and Anus, New York Post-Graduate Medical School and Hospital.

Minor injuries are frequently observed at the anus and lower rectum, but extensive, dangerous, contused, lacerated, and perforated intestinal wounds most frequently involve the abdomen, small intestine, and colon. The rectum and anus are less often subjected to trauma, because of their position within the buttocks, and protection of the surrounding bony structures (symphysis pubis, sacrum, coccyx, iliac bones, and their tuberosities). The rectum may be injured from above through contusion, bullet or knife wounds, or from below, particularly when the subject is bent forward when the injury is received.

Types of wounds and injuries. Wounds of the anorectal region may be classified as contused, lacerated (ruptured), incised, perforating, pneumatic, and miscellaneous.

Contused wounds are encountered less often about the rectum than the colon, and are usually induced by being run over, kicks, blows, falling from a height upon the buttocks, divulsion of the sphincter, evacuation of hardened feces, careless instrumentation, and pessaries.

Laceration and rupture of the rectum and anal canal are common, and may be slight or very extensive. Most often laceration results from the discharge of impacted fecal matter, or careless introduction of the finger, hand, or speculum, proctoscope, bougie, or other instrument.

The author has treated many diminutive, moderated, and extensive lacerations of the mucosa, and other rectal coats, caused by enema tubes that were rough, sharp, pointed, or which had been forced into the bowel tunics, or broken, following which hemorrhage, abscess, or peritonitis was a complication. He has treated other patients where injury was induced by a kick or blow on the anus, pederasty, divulsion of the sphincter, or strictures caused by dilators or bougies, tearing of the gut during operations on the bladder, prostate, or pelvic or abdominal organs, evacuation through the rectum of a large vesical calculus, or of foreign bodies, viz., fish and chicken bones, enteroliths, safety pins, nails, fish hooks, fragments of glass, and triangular pieces of metal.

Cases have also been reported where the patient had been run over, or run into by a wagon tongue, had fallen from a height, sat down on or had been thrown against a blunt or ragged object, viz., a

*Read before the American Proctologic Society, Detroit, 1916.

stone, stump, paling, scissors, door knob, pitchfork, or dashboard of a wagon, had been crushed by machinery or hit by flying missiles.

The rectum has been ruptured in several patients, where bougies were forced through strictures above the peritoneal attachment, and similar injuries have been caused by the careless or forcible introduction of the sigmoidoscope, and passage of instruments or bougies by experienced surgeons, where the bowel was strictured, extensively ulcerated, or involved in a cancer. Ruptures have also followed distention of the bowel by air or gas for diagnostic purposes, stretching and massaging the gut with inflatable rubber bags (for constipation), and the introduction of compressed air in a spirit of fun. Similar injuries have followed introduction of the hand during examination, and employment of large operating specula, and where the subject had been squeezed by machinery, caught between colliding cars, or injured by shrapnel.

Incised wounds. Accidental, clean cut wounds of the rectum and anus are usually made by the knife or bayonet, but may be the result of sitting or falling upon a pointed or edged instrument or object, evacuating bones, pieces of glass, nails, tacks, burglar files, or other foreign bodies having an angulated or sharp edge. The rectum is also frequently injured during operation upon the bowel and adjacent organs.

Rectal tears are occasionally induced by the head during labor, escape of skull bones through the anus, bursting of abdominal, pelvic, and spinal abscesses, encroachment of a displaced coccyx, introduction of sounds and catheters, and crushing operations for vesical calculi.

Perforating wounds, by penetration or puncture Perforation of the small intestine and colon are more frequently caused by typhoid ulcer and infectious types of colitis, than by accidental injuries.

Perforations of the rectum may be induced by a bullet, knife, or bayonet thrust, or pointed or sharp edged foreign body (pin, needle, knife, piece of glass, etc.), swallowed or introduced through the anus. Occasionally prisoners and insane persons swallow or conceal foreign bodies in the rectum, and the author has treated two men who swallowed nails, glass, needles, pins, and open knives for a living, that died from perforation and peritonitis. Frequently the surgeon's knife, needle, or scissors accidentally punctures the bowel during rectal, pelvic, vesical, prostatic, or urethral operations, and occasionally scissors, knives, forceps, needles, gauze, ligatures, and other foreign objects or substances, left in the abdomen, perforate and are evacuated through the rectum. One of the most frequent and unnecessary causes of perforation is the careless introduction of imperfect or glass enema tubes, which readily break when force is used.

The author has treated four patients for complete bowel laceration, made by careless surgeons who used unsuitable instruments while packing wounds, and has seen another case where injury was caused by distending the rectum with gauze, during an attempt to control hemorrhage.

Ischial abscesses nearly always point in the rectum, but pus from pelvic, spinal, and coccygeal abscesses occasionally discharge into the bowel.

Pneumatic wounds. Distention of the rectum and colon with air or gas is a diagnostic aid in certain cases, but when carelessly practised, rupture may ensue from overdistention. Several times, perforation has followed employment of the pneumatic sigmoidoscope, owing to high air pressure or to forcing the instrument through the bowel. Lacerations and rupture of the rectum have also followed dilatation, massage, and stretching the rectum with air filled rubber bags, in the treatment of chronic constipation and stricture. Pneumatic rupture of the rectum most frequently happens as a result of joking, and recently several cases have been reported.

Many factories employ compressed aid to blow away filings, shavings, and dust, cleaning flues, motor power, and riveting bolts, and employees often use it to clean their clothes; the air being permitted to escape through a narrow nozzle at a pressure of from forty to 125 pounds. When a new employee enters the factory, he is sometimes initiated by having the air turned upon him, which causes a sharp stinging sensation. In ninety-five per cent. of rectal and colonic ruptures from this source, the victim is bent over, and the tube is placed at or near the anus, and the air turned on in a spirit of fun; in nearly every instance the air penetrated the clothing, entered the anus, and ruptured the small intestine, colon, sigmoid flexure, or rectum, which was immediately followed by an outcry, and fainting or collapse of the victim. The rupture usually occurs in the sigmoid flexure, but in some instances the bowel tears at several points, or throughout its entire length, and the blowout is complete; but sometimes the peritoneal and muscular tunics give way and the mucosa extrudes through them.

Other wounds and injuries. Injury to the rectum and submucous and subcutaneous tissues is frequently caused by the injection of carbolic acid in the treatment of hemorrhoids. The author has handled cases where ignorant employment of this agent led to violent inflammation of the anorectal region, abscess, fistula, terrific sloughing, embolism, and pneumonia. Several times he has treated extensive burns, resulting from the improper use of acids, turpentine, zinc paste, silver nitrate, and electric or Paquelin cautery, and has frequently been consulted by patients who suffered from painful injury, induced by the snapping of the blades of a speculum, or a sharp edged proctoscope. Finally cases were encountered where the buttocks and anal canal had been slightly or extensively lacerated by the patient's finger nails, while scratching to relieve pruritus ani.

SYMPTOMS.

The manifestation of anorectal injuries varies with the extent, character, and site of the wound, time elapsed between occurrence and operation, and whether or not the wound drains freely.

Traumatic lesions of the upper rectum and sigmoid flexure are more serious than lower rectal, because they are often complicated by peritonitis. Contused and lacerated injuries induce dangerous manifestations less frequently than punctured wounds, because they are larger, frequently superficial, and drain freely.

Blow outs or pneumatic ruptures of the rectum or colon are the most serious of intestinal accidents, since the gut is torn through, and blood, gas, feces, and pathogenic organisms escape into the abdominal cavity, to cause peritonitis, abscess, or fecal fistula.

Superficial injuries and foreign bodies in the anal canal, through irritation, induce pain, tenderness, soreness, tenesmus, and spasmodic contraction of the sphincter and levator ani, and occasionally incontinence of urine or frequent micturition. Deeper wounds similarly situated cause the same symptoms. When they do not drain freely, infection ensues, then the patient has a chill, high temperature, fast pulse, throbbing pain, furred tongue, and the usual symptoms of abscess.

Extensive ruptures and tears below the peritoneal attachment cause little suffering, after the initial pain subsides, because they drain freely, and the sphincter muscle is often severed. Exceptionally, infection takes place or sloughing ensues from injury to the vessels or tissues, and septicemia or toxemia is troublesome, and continues until drainage is perfected or necrotic tissue has been removed.

Shock. Minor and major injuries of the rectum below the peritoneal attachment cause little or no shock, except when considerable blood has been lost, but contused, lacerated, and pneumatic wounds, affecting the abdomen, upper rectum, or colon, are usually accompanied by profound shock, and the patient remains in a state of collapse until the injury has been repaired.

Hemorrhage. Bleeding often complicates intestinal wounds, and is slight, moderate, or profuse, depending upon the size of the vessel injured. Clotted blood in the abdomen evidences extravasation, and favors peritonitis when it is not removed. Occasionally, alarming secondary hemorrhage from sloughing occurs where vessels have been severely traumatized.

Sepsis. Primary union is obtained in clean cut wounds, but infection resulting in peritonitis, abscess, or fistula is a frequent complication of injuries involving the peritoneum, and penetrating, ragged, and uneven wounds that are not drained properly.

Abdominal distention and tympanites quickly follow perforation, laceration, or rupture of the small or large intestine or rectum, above the peritoneal attachment.

Urinary incontinence or difficult micturition is observed where the bowel and the external sphincter and levator ani have been severely traumatized. Abdominal pain and tenderness complicate complete tears in the large bowel, and intense colic is characteristic of pneumatic rupture of the gut. The pulse and temperature remain normal when the lower rectum has been injured and properly drained, but are disturbed when the wound is infected, or involves the colon or sigmoid.

Complications. The following are the chief complications of anorectal wounds: Abscess, rectovaginal, rectovesical, or rectourethral fistula, fecal incontinence, stricture, hernia, fecal fistula, urinary or fecal extravasation, sloughing of the mesentery, peritonitis, phlebitis, pneumonia, and necrosis of the sacrum, coccyx, or pelvic bones.

DIAGNOSIS.

Anorectal injuries are comparatively easy to diagnose when a history has been taken, the manner in which the accident occurred is learned, external evidences of trauma are observed, symptoms are studied, and the degree of bruising, ecchymosis, swelling, edema, and laceration of the perianal skin and abdomen are noted. Following inspection of the lesion, digital and proctoscopic examination is practised, where the rectum is involved, so that the tear or perforation can be seen or felt, to determine its extent. Promiscuous probing is dangerous and unsatisfactory.

When the upper rectum, sigmoid flexure, or colon is apparently injured, the abdomen is opened, and the intestine examined, until the wound is located. Perforations and tears in the rectum or lower sigmoid are also diagnosed through the sigmoidoscope and by infiltrating the gut with air, which escapes into the abdomen when it is lacerated.

TREATMENT.

The treatment of anorectal injuries is simple or complicated, but under all circumstances the wound is immediately cleansed and bleeding arrested, so that the character of the wound may be determined. Incised or clean cut injuries are closed with deep and superficial catgut stitches, the suture line is protected by collodion or gauze, and a drain is inserted in the dependent extremity of the injury to prevent infection. Contused, lacerated, and pneumatic wounds in the lower rectum are drained at one or more points after hemorrhage has been arrested, ragged edges have been removed, and the wound irrigated. Dressings are not applied until the wound has been levelled, so that cuplike depressions are not left to catch infective agents. In extensive injuries sections of the wound are sutured with catgut before the drain is inserted, in order to shorten convalescence.

During postoperative treatment the patient suffers less, and the wound heals more quickly when the patient eats full meals, and the evacuations are kept normal or semisolid, for fluid stools cause pain and favor infection, and nodular feces traumatize the wound.

Where the bladder or urethra is perforated or ruptured, in suitable cases the tear is immediately repaired, and the rectal injury treated according to the plan outlined above, but when this is not feasible, the bladder is drained, and the urethral or vesical wound heals by granulation.

Abdominal rectovesical wounds are difficult to close, but when this has been successfully accomplished, with through and through Lembert sutures, results are good, except in delayed infected cases.

Diminutive and large rents in the colon and sigmoid are repaired by a purse string, or by double infolding sutures; but where the mesenteric vessels are injured, or the rectum, sigmoid, or colon is extensively damaged, the bowel is resected, excluded or sutured, or an artificial anus is established by suturing the gut in the abdominal incision.

In rectovaginal perforations and tears, better results are obtained when closure of the vaginal opening precedes approximation of the rectal edges of the rent. Sutures employed in closing deep wounds

are severed when signs of infection appear, and the necrotic tissue is excised or dusted with calomel.

In abdominal injuries, where blood, feces, or urine is found in the abdomen, it is wiped out, the cavity irrigated with saline solution before the rent is repaired, and drained to lessen the danger of infection and peritonitis. Following repair of recto-abdominal injuries, patients do better when they are kept in Fowler's position, and on fluid diet for a few days. Continuous cold antiseptic applications are agreeable, prevent infection, minimize the danger from infection, and facilitate the healing of contused skin and abdominal wounds, associated with anorectal and colonic injuries.

Miscellaneous injuries. When the rectum and skin are burned with acid, zinc, silver nitrate, or turpentine, antidotal agents are immediately applied to the injured area, followed by a bland ointment containing morphine or cocaine, to relieve pain, diminish sphincteralgia, and prevent contractions of the levator ani. Later, when the patient is comfortable, mild stimulating applications to the wound facilitate healing.

AURAL COMPLICATIONS OF GRIPPE.*

By Edward B. Dench, M. D., F. A. C. S.,
New York.

In considering the aural complications of epidemic influenza, the first point which I wish to emphasize is, that the aural manifestations do not differ essentially from the aural manifestations which we find occur when this constitutional disease is absent. Much has been said in recent years about the unusual prevalence of middle ear suppuration complicating epidemic influenza. This is undoubtedly true. At the same time, I doubt whether any other epidemic disease of equal severity, and involving the upper respiratory tract, would not be followed by aural complications quite as frequently as aural complications occur in epidemic influenza. In other words, influenza otitis presents few characteristic points peculiar to itself. It presents general characteristics depending upon the lowering of body resistance due to a severe constitutional disease. Given this lowered body resistance, the aural condition, in my opinion, would be exactly the same whether the constitutional disease was epidemic influenza or some other constitutional condition of equal severity.

The most simple aural complication which we have in epidemic influenza is a mild congestion of the tympanic cavity and of the Eustachian tube. The only way that this differs from a similar condition following an acute coryza, is in the rather sudden appearance of the aural symptoms and the rapidity with which they advance. Seen early and treated properly, these symptoms disappear as readily as if they were complications of a simple cold in the head.

When we come to the acute inflammations of the middle ear complicating epidemic influenza, they may be divided into two classes.

First, those which are characterized by a sudden accession of the symptoms, such as severe pain, abrupt rise in temperature, and rapid changes in the tympanic mucous membrane, these changes occurring very rapidly—much more rapidly than they would occur as a complication of a simple cold in the head. These cases are easily recognized, and prompt local measures for their relief are usually followed by satisfactory results. There is one type which is rather characteristic of influenza otitis. I here refer to what we may call the hemorrhagic type of acute otitis. In acute inflammation of the middle ear characterized by a sudden onset of the constitutional symptoms, we frequently find on speculum examination a hemorrhagic condition in the external auditory canal, involving, not only the walls of the canal, but also the superficial layer of the drum membrane. In other words, an acute otitis externa hæmorrhagica is a frequent complication of acute otitis media complicating influenza.

There is, second, another type of influenza otitis far more dangerous than this presenting the acute symptoms, and that is, the so called latent otitis media. We have a history of an acute influenza with moderate constitutional symptoms. There is also some pain in the ear, and speculum examination may show a simple congestion of the tympanic membrane, in other words, a mild middle ear inflammation. The aural symptoms may continue mild in character for a few days, and then suddenly there may be an abrupt rise in temperature and all the symptoms of constitutional infection due to absorption from the local focus of suppuration in the middle ear. In one case of this kind which I saw this winter, an otitis of only five days' duration was followed by a sinus thrombosis necessitating excision of the internal jugular; the blood culture, five days after the inception of the otitis, showed streptococci.

Mastoid complications following an influenza otitis are, perhaps, not more common than mastoid complications following an otitis of equal severity and depending upon other causes. In mastoid involvement following influenza, however, a hemorrhagic type is not infrequent. Hemorrhagic mastoiditis is characterized by severe mastoid pain from the onset of the acute attack, also by more temperature elevation than we ordinarily find in a simple aural mastoiditis. On opening the mastoid we find the cells filled with dark blood or black clotted blood. The septums dividing the pneumatic spaces are ordinarily intact, but the hemorrhagic condition extends throughout the entire mastoid process. Most cases require early operation. In the majority, convalescence is prolonged, and in only a very few cases is any treatment other than the open method admissible. In other words, given a case of hemorrhagic mastoiditis, the infection is usually so widely spread throughout the mastoid, while at the same time no limiting membrane has been developed, that suture of the superficial structures means simply secondary wound infection. If these wounds are treated by the open method and are simply packed, convalescence is rapid. If nearly complete closure of the wound is employed, convalescence will be very much prolonged. The hem-

*Read before the Medical Association of the Greater City of New York, March 20, 1916.

orrhagic type of mastoiditis is perhaps more common as a complication of influenza than of any other constitutional disease. Where the mastoiditis is of the ordinary variety, as characterized by a breaking down of the intercellular substance of the mastoid and the formation of pus, the influenza cases do not differ from the cases of ordinary suppurative mastoiditis, except that the progress of the disease is apt to be more rapid owing to the lowered resistance of the patient.

The points that I should like to bring out, therefore, are as follows:

1. Aural complications of influenza are severe chiefly from the fact that the constitutional infection lowers the general bodily resistance.

2. The hemorrhagic type of inflammation, both in the middle ear and in the mastoid process, occurs probably more frequently as a complication of influenza than other constitutional diseases.

3. Operative interference in these cases must depend upon the otoscopic appearances and the local symptoms. In other words, the actual local lesion determines the character of the surgical interference.

To be certain that the aural complications of influenza are not confined to this particular constitutional disease, we have only to look at our large general hospitals, where a comparatively large number of cases of epidemic influenza are treated each year, and to note the relatively small number in which severe aural complications occur. Also, in special hospitals the occurrence of an epidemic of influenza does not increase the demand for attention, as would be the case were the aural complications so exceedingly common in this disease as many give us to understand. In other words, epidemic influenza, when it occurs, is exceedingly widespread. Naturally, a certain number of these cases will suffer from aural complications, but that a very large proportion will suffer from aural complications cannot certainly be proved by statistics.

That this view regarding the nonspecific character of the otitic complications is correct, is borne out by the bacteriological findings. In cases of so called influenza otitis, the infecting organism is almost always a streptococcus. This organism, as we know, is the organism most frequently found in severe middle ear inflammation. I have yet to see a single case of mastoiditis and, as I remember it, a single case of middle ear infection, due to the specific organism of influenza.

The mild cases of middle ear inflammation which complicate epidemic influenza are most frequently seen by the general practitioner, and many times by him alone. It is important that every general practitioner should be able to recognize a beginning acute inflammation of the middle ear and should understand what measures he may safely take for its relief. He should also recognize his limitations; and where the condition demands it, or where he is in doubt, he should remember that prompt measures in the early stages may do much to prevent serious complications later. I am inclined to think that a large proportion of the medical profession temporizes with beginning acute inflammation of the middle ear; at least, I know that not infrequently I am called in consultation and receive a history somewhat as follows: The patient had a mild attack of influenza. There was some discomfort in the ear, not amounting to severe pain. The temperature elevation was only slight, and otoscopic examination revealed but slight changes in the drum membrane—probably slight congestion along the long process of the malleus. This condition may mean much, or little. Not infrequently, the general practitioner commits the blunder of ordering the ear irrigated with a warm solution to relieve the slight pain, or I am afraid this irrigation is ordered because he feels that something must be done. It should be remembered that while irrigating an ear with warm water is practically harmless, the mere introduction of water into the external auditory canal will cause a temporary congestion along the long process of the malleus and about the periphery of the membrane. If such irrigation is ordered frequently, and then the symptoms increase, the otoscopic appearance will be somewhat masked by the irrigation. Particularly, I think, the general practitioner should remember that no water is to be introduced into the external auditory meatus for the relief of pain, unless there is a discharge from the ear. If the case is one of acute otitis in its early stages and is going to resolve spontaneously, the application of moist heat will not aid the process of resolution, while its use has the disadvantage of masking the otoscopic picture. If spontaneous resolution is not going to take place, then free incision of the drum membrane is demanded. It is this temporizing in the early stages—delaying incision of the drum membrane unnecessarily, and trusting to the supposed advantages of moist heat—that I think is responsible for many of the more serious complications which follow acute otitis media.

Coming now to the operative treatment of the aural complications of influenza, I have stated that operative interference in these cases will depend upon the otoscopic appearances and the local symptoms. Much misunderstanding has occurred among the laity by the indiscriminate use of the word, mastoiditis, and the limitation of this term to cases where the aural complications are of great severity and where operative interference has been undertaken sometimes as a last resort. The general practitioner should aim to make his patients understand this fact—that the mastoid is a part of the middle ear and that every acute inflammation of the middle ear is undoubtedly accompanied by certain changes in the mastoid process. In other words, every acute otitis media is an acute mastoiditis. In the milder cases, an external operation upon the mastoid is unnecessary. The pathological condition within the mastoid process is relieved by free drainage of the middle ear through an incision of the drum membrane. In certain cases, either due to the severity of the infection, or to the fact that some remote portion of the mastoid becomes infected—either at the same time that middle ear infection occurs or at a subsequent period—middle ear drainage is not sufficient to relieve the condition resulting from invasion of the mastoid. In such cases it is necessary to drain the focus of inflammation posteriorly; in other words, to perform the mastoid operation. It is not so many

years ago that the laity were extremely timorous regarding incision of the drum membrane and looked upon this procedure as one of great gravity. They have been educated gradually to understand that a free myringotomy is not only often a life saving measure, but that it is almost always a measure of the utmost value in preserving the function of the auditory apparatus. In the same way they should be taught that where tympanic drainage is not sufficient to relieve a pathological condition within the mastoid, an early mastoid operation is devoid of danger and offers the best opportunity for conserving the function of the organ of hearing.

NOSE AND THROAT COMPLICATIONS AND SEQUELÆ OF GRIPPE.*

With Suggestions for Preventive Treatment.

By William Ledlie Culbert, M. D.,
New York.

Each succeeding year brings its own particular type of infectious troubles, usually classified as grippe; but as a matter of fact even a cursory review of the literature for the last fifteen years shows that there is nothing especially new in the manifestations of the disease. Moreover, it is probable that the specific organism produces a specific effect, modified by the resistance of the victim and the point selected for attack.

Atypical and unusual cases are probably due to a more or less mixed infection. The *Weekly Bulletin* of the board of health, issue for February 26th, states that of fifty cases diagnosed as grippe, and diagnosed by Doctor Williams, both microscopically and culturally, the influenza bacillus was found in only nine, while the streptococcus was found in twenty-six, and the pneumococcus in nineteen. In many of the cases a number of different organisms were noted; that is to say, in the majority of cases we were dealing with a mixed infection.

To enumerate the complications and sequelæ of grippe and allied conditions in the upper respiratory tract, would involve the naming of practically all the anatomical structures of this region with their inflammatory affections, both acute and chronic. It is not necessary to attempt to draw a fine distinction between the manifestations of the disease proper and of its complications. For practical purposes, we may consider that the ordinary cases of grippe are manifested at first only as severe acute rhinitis, with extensive involvement of some or all of the accessory sinuses; but when the process extends, for example, into the lacrymal duct, the Eustachian tubes, the tonsils, or the deeper part of the respiratory tract, it may properly be considered as a complication or sequel.

Stated simply, influenza bacilli generally obtain their first foothold in the nasal mucous membrane, giving rise to the manifestations of an ordinary acute coryza, with consequent swelling of the membrane, interfering with drainage from the nasal cavity itself, and the small ducts which drain and ventilate the nasal accessory sinuses, any or all of which may be attacked. With such an involvement, the constitutional symptoms may be very pronounced—rise of temperature, aches and pains in the head, back, and limbs—with local symptoms of a blocked up nose, more or less pain, and profuse serous secretion.

The process may remain simply catarrhal in its nature until the disease is checked or runs its course; but when the organisms are unduly retained in the cavities by abnormal anatomical structure of the nose, they develop rapidly, and the symptoms are more or less severe, depending upon the virulence of the organism and the resistance of the victim.

The ethmoid, with its inadequately drained cells, called by the older anatomists the ethmoidal labyrinth, forms a peculiarly favorable site for the reception and propagation of these bacilli. Loss of smell is usually one of the first results of ethmoidal infection. Sometimes the pus in the posterior ethmoidal cells invades the optic nerve, and causes scotoma, thereby producing partial or total blindness. The proximity of the ethmoid to the brain cavity and its connections therewith by numerous small foramina transmitting bloodvessels and lymphatics, accounts for the not infrequent cases of meningitis that develop as a sequel of this affection.

The first attack of grippe usually subsides under ordinary treatment, but in cases where there have been repeated attacks, followed by ethmoidal disease with the formation of polypi, the most severe complications generally develop.

Case I. Some time since I was asked to see a young man who had had several attacks of grippe, and was then suffering from another severe attack. He had a temperature of 104.5° F., severe frontal headache, and his left eye was protruding. Examination showed pus in the left nostril and nasopharynx, with intense congestion of the mucous membrane and turbinate bodies. A diagnosis of suppurative ethmoiditis perforating the orbit, complicating grippe, was made. The patient was removed to the hospital, and skiagraphs were made which showed a pansinusitis on the left side. All attempts at treatment failing to drain the sinuses or relieve the pain, a radical Killian operation was performed. Pus was found in the frontal and sphenoidal sinuses, pus and polypi in the ethmoid and antrum. After opening the orbit, pus and gangrenous fatty tissue were removed. For a time it was doubtful if the sight of the left eye could be preserved, but a good constitution enabled the patient to recover normal vision and health.

The drainage from all the inflamed area of mucous membrane naturally follows the line of least resistance, and usually flows into the nasopharynx, irritating and swelling the mucous membrane of the pharynx, and causing more or less cough, often persistent and aggravating; or, reaching the tonsils, it may infect them and through them produce an acute cervical adenitis; or localizing itself around the tonsils, may form a peritonsillar abscess; or it may even burrow through the mucous membrane of the posterior pharyngeal wall and cause a retropharyngeal abscess. This later complication is more common in children than in adults.

From the buccal cavity the bacillus may gain access to Stenson's duct and thus set up an inflam-

*Read as part of symposium on grippe at a stated meeting of the Medical Association of the Greater City of New York, March 20, 1916.

mation of the parotid gland. This complication is not more common in influenza than in other infectious diseases, but it is a point to be remembered with parotiditis coming on during or after grippe, particularly in adults. The writer had a case in which the sublingual gland was attacked through its ducts in the floor of the mouth. Doctor Bane, of Denver, has reported a case of Ludwig's angina due to Bacillus influenzæ, in which a pure culture was obtained from the pus escaping from a spontaneous evacuation, from which an autogenous vaccine was made and administered. The patient recovered. (*Trans. Am. Lar. Rhi. and Otol. Soc.*, 1914, p. 338.) When the discharge is profuse, often consisting largely of pus, the patients not infrequently are unaware of it as it passes into the pharynx, and it may flow either into the larynx and set up an irritation or infection there, or into the esophagus and so cause stomach or digestive troubles.

We must not be misled into thinking, however, that the grippe organism must of necessity manifest itself first through nasal symptoms. It may localize itself and attack other portions of the respiratory tract primarily, with marked virulence.

Case II. For example, a patient was first seen by his family physician on a Saturday morning, at which time he complained simply of a slight cold and sore throat. The doctor could see nothing special in the throat. The next morning, he was called in early to see the patient, who then had marked stridulous breathing. The writer was called in consultation and found the margin of the glottis very edematous, the sharp outlines of the arytenoids and adjacent structures being almost obliterated. Remedial measures failed, and within twenty-four hours it was necessary to do a hasty tracheotomy, as the patient was cyanosed and the glottis entirely closed. Six hours later, a pneumonic patch was found in the right lung; the next day the lung was entirely solid. The sudden appearance of this pneumonia could not have been due to the tracheotomy. The third day, the kidneys ceased action, and the patient died. A blood culture taken on the second day showed a severe pneumococcus bacteriemia. This case is cited to illustrate an acute clinical grippe infection, with the selective point of attack in the mucous membrane at the entrance to the larynx, developing into a general pneumonic process.

For a considerable time after attacks of grippe, patients frequently complain of difficulty in breathing, and examination of the nares reveals a hyperemic condition. Kyle, of Philadelphia, has shown that the occlusion is not an edematous swelling, but a true thickening of the membrane, due to an albuminous exudate in the perivascular spaces, which exudate, he believes, is formed in the blood by the action of the specific toxins of the bacilli. This possibly explains the persistence of grippe infections in the sinuses, and their tendency to become chronic or to recur, especially when they are not treated effectively after the initial attack.

In the preventive treatment of infectious grippe, three main points must be considered: 1, The condition of the mucous membrane and the anatomical structure of the nose; 2, the resistance of the subject; 3, the environment, which in our crowded cities is a most important factor.

As is well known, the nose has three main functions to perform in regard to respiration: moistening, warming, and filtering the inspired air. It is therefore of the first importance that this natural filter be kept clean and unobstructed, in order to prevent the development of germs within its confines or their further penetration into the respiratory tract. Deviated septums or enlarged and unhealthy turbinated bodies, especially with points of contact, should receive proper attention. The main point, however, consists in the education of the patient. Children, especially, can be readily taught how to blow the nose properly, and keep it clean. Grease in some form—plain petrolatum, perhaps as well as anything—may be instilled into the nose at stated intervals, to soften secretions and render cleansing easier. Furthermore, it seems reasonable, especially in children, that breathing exercises persistently carried out, would develop and improve the function of the nose.

The systemic resistance of the body must be maintained and improved by attention to diet, exercise, and general hygiene, avoiding overfatigue, exposure, or undue strain. Where repeated attacks of grippe have occurred and the system is greatly debilitated, the mixed vaccines may in some instances aid in restoring normal balance.

A healthy out of door life is, of course, the ideal, and is rarely attainable. When grippe is epidemic, patients should be instructed to avoid crowded assemblages, and to protect themselves as much as possible from known sources of infection.

16 East Fifty-fourth Street.

THE FAUCIAL TONSILS IN SINGERS.

Should We Remove Them?

By Irving Wilson Voorhees, M. S., M. D.,
New York.

In the entire realm of surgery no other operation is so frequently performed as that for total or partial removal of the faucial tonsils. Removal is universally regarded as an extremely simple procedure, and the public has come gradually to the belief that any one holding a degree in medicine is perfectly capable of "doing tonsils." Nevertheless, those of us who see a large number of postoperative cases are frequently brought face to face with ineffectual and untoward results. In many instances the operator never learns of the final outcome, and acquires the belief that all of his patients obtain one hundred per cent. cures whatever results his neighbor may be willing to confess. Recently we have been surprised to learn that at least five children operated upon by qualified tonsil surgeons at a recognized nose and throat hospital during the past six months have languished for some weeks in a large general hospital with foreign body pneumonia or empyema or both. One of these, a girl of seventeen years, came to my office for another condition, and the fact that she had had a resection of some ribs for empyema came out in the course of taking a history. She said that while having her tonsils removed she had "caught cold" and had almost lost her life, but was saved by a skillful thorax operation at the hands of the general surgeon who referred her to me. At the special hospital no knowledge of this complication had ever reached the ears of any of those who would be most interested to know about it.

However, considering the thousands of patients

who go through tonsil procedures, the number who suffer from any complication worthy of mention is surprisingly small. This fact does not absolve us as specialists, however, from keeping an ever watchful eye on our technic. On the contrary, it should make us cautious about advising operation when it might be avoided. In no class of patients is this more to be borne in mind than in our dealings with singers, whose requirements are so very special that the slightest relaxation in our vigilance might spell disaster. Disorders of the nose and throat which in other persons mean little or nothing in the daily round of existence, are in singers fraught with consequences that are sometimes surprising considering the paucity of discoverable symptoms. Therefore, when we advise removal of the tonsils in singers we must weigh carefully all the known factors making for a successful result, and must not forget that unknown factors can bring about a failure.

Whatever may be said for or against tonsillectomy in other persons, in singers it is a matter of vital importance. During the past few years the laryngologist has been confronted daily by the eternal question, Doctor, if I have my tonsils removed, do you think there is any danger of my losing my singing voice? The patient who frames this interrogation usually has a long story to tell of some one who knew some one who had the tonsils removed and was never able to sing thereafter. It is nearly always a hearsay story. Seldom indeed do we find any one who has seen a "before and after" demonstration of this disability. Many singers, when questioned, acknowledge that they can recall no specific instance of lost singing voice following tonsil removal. Nevertheless, feeling that this subject is worth sifting out, and in order to get first hand information, a questionnaire was sent out to 500 physicians and to 500 singing teachers. A surprisingly large number of answers were received, and it was gratifying to note the interest that the matter seemed to inspire. Many of the busiest and best known men not only answered the questions, but took the trouble to write a personal letter as well. This personal element has added greatly to the interest of compiling and classifying the necessarily varying opinions. I shall present the evidence adduced seriatim:

TO PHYSICIANS.

Question 1. How many singers approximately have you tonsillectomized? One hundred and eight men reported 3,427 tonsillectomies. Of these some could not spare the time to look up records, others kept no records, and five were against operating on singers at all.

Question 2. Did cicatricial contraction of the pillars and soft palate result in any case? Out of 341 cases only forty-six showed cicatricial contractions, which is truly an excellent operative record. On the other hand, one gentleman said he had "observed" two hundred cases, operated in by other surgeons, "many" of which showed such contractions. Another surgeon had "treated" 100 postoperative cases, in twenty-two of which (twenty-two per cent.) he found cicatricial contractions in the fauces. It is fairly impossible to form any accurate judgment of this matter owing to the guesswork with which many physicians seem to be laboring. The words "many," "few," "several dozen," "great number," etc., show the mental haziness which descends on our horizon when we try to collate facts for scientific purposes. However, in order to strike the average, we may say that cicatricial contractions seem to be present in about one sixth of the total number of cases reported.

Question 3. What were the effects of tonsil operations on the singing voice? A, good, B, bad, C, no change. This is the salient question in the inquiry, and yet it was frequently answered in slipshod fashion or overlooked entirely. One hundred men reported good results in approximately 2,849 cases; while twenty-nine men reported no change. Four physicians declared absolutely bad effects, but did not go into particulars as they were especially requested to do; therefore, we are in the dark as to what these bad effects were. Two of these four men had never operated and the other two had done "very few" operations. Both declared their observations to be based on a "large" number of postoperative cases sent to them for inspection.

Question 4. Were these effects temporary or permanent after one year? In all cases the *good* effects were permanent. In cases where untoward or bad effects were noted, they disappeared within from one to three months after operation. No bad effects seem to have persisted after the third month A great many men expressed dissatisfaction in not being able to follow up their cases in a proper manner, since pupil singers migrate to the larger towns and to Europe. In general, singers as a class are fond of consulting many different specialists in the cities where they visit.

Questions 5 and 6. What bad effect, if any, was complained of, and what do you think was the cause of this bad effect? Ninety-five men reported no bad effects in a total of 2,904 cases. One holds the proud record of 300 tonsillectomies without a single bad effect of any kind. Thirty-eight men reported bad results in 172 cases. These were in outline about as follows:

Vocal stiffness for a few weeks. Decreased volume and impaired quality.

Difficulty with the flexibility of the top voice.

Voice lowered and range limited.

Difficulty in placement or loss of placement.

Loss of purity and sweetness of tone.

Metallic quality.

Vocal fatigue after vocalization.

Dryness of throat and sensation of a feather tickling the throat.

"Catch" in the voice.

The causes of these untoward symptoms as viewed by the specialist, were: Faulty technic whereby the pillars and soft palate were injured, changes in the faucial contour due to cicatricial contractions, involvement of fibres of the glossopharyngeal nerve, temporary incoordination of vocal musculature, lost lubricating function of the tonsils, relaxed pillars, necessitating a rearrangement of the resonating influence of the pharynx and nasopharynx, using the voice too soon after operation.

One surgeon reports 3,500 tonsillectomies. Of the subjects about fifty were singers, and in none

was there any difficulty except "stiffness of the throat" for a few weeks.

Question 7. What type of tonsil (buried, small, hypertrophied, pedunculated, etc.) in your opinion gives the best chance of voice improvement after removal? All are practically agreed that the hypertrophic tonsil offers the best hope of improvement. The best answer probably is that any diseased tonsil, whether large or small, should be removed if such disease and resulting symptoms have been established beyond a peradventure. Some years ago, Professor O. Chiari, of Vienna, showed that greatly hypertrophied tonsils may be removed with impunity only if we calculate beforehand how to prevent relaxation of the palatoglossus and palatopharyngeus. Removal of such a mass of lymphoid tissue leaves a large fossa which must be filled in by granulation tissue and a subsequent cicatrix. I have always felt it wiser in such a case to do a tonsillotomy and to treat the cryptic stumps with chromic acid or the electrocautery after healing is fairly established. This brings us to the crucial question.

Question 8. Do you know of any case in which the singing voice was apparently destroyed by a tonsil operation? Only fifteen men out of 133 confessed a knowledge of any case in which the singing voice had been destroyed by operation. The inquiry was intended to apply to patients who had been obliged to give up all effort to sing after tonsillectomy. One man replied, "Lots of them, as a result of injuring the pillars during radical extirpation. I consider enucleation *with the capsule injurious* to the voice because of resulting prolapse of the pillars, and I apply the old rule, to remove only diseased or hypertrophied tissue." In one case "harm was done to the voice by a bungling operation."

Doctor ——— reports two patients "who stated that they were never able to sing after tonsillectomy," but adds naïvely that he doubts whether they could sing before the operation either!

Sifting down the "evidence" of these fifteen laryngologists who align themselves against tonsil operations in singers, such evidence is intensely vague, uncertain, and seems, after all, to be based mainly on hearsay.

Question 9. To what circumstance or technical fault do you attribute this destruction? There seems to be a unanimity of opinion that faulty technic is at the bottom of any postoperative difficulty. The phrase, faulty technic, occurs again and again, while injury to the pillars, laceration of the uvula and soft palate, too extensive cutting or tearing of parts adjacent to the tonsil, and ignorance of anatomy and function of the tonsils are other ways the reporters have of describing the causes of vocal impairment as they view it. A certain physician complains of those "who operate without anesthetics in sensitive throats which patients cannot control during operation." Surely any one who attempts, without anesthesia, any kind of operation on the highly strung, supersensitive singer is guilty of a serious offense.

Thus far we have considered only the reports coming out of the experience of the laryngologist. Let us now take up the replies to the questionnaire set for singing teachers only. There was a great deal of difficulty in reaching the teachers, because their national organization has few members and there is no roster of the States such as the *American Medical Directory* affords. A large number of those addressed replied, but the writer regrets that he was unable to secure a longer list.

Question 1. How do diseased or enlarged tonsils affect the singing voice? The general opinion among singing teachers is that the tonsils muffle or deaden the voice, take up space needed for perfect vocalization, interfere decidedly with the amplification of tone, make the voice thick and throaty and limit its compass, diminish the pharyngeal and nasopharyngeal (head) resonance, affect the general health, cause liability to colds and weak throat, and prevent the expansion of the throat necessary for high voice.

Question 2. How many of your pupils approximately have had their tonsils removed? About ten to twenty per cent. of vocal students some time in their career undergo tonsil operations. One teacher says that a large percentage of so called throat trouble is caused by diseased tonsils, and recommends all such persons to undergo the operation before beginning vocal work.

Question 3. Was the removal total or partial? The consensus is that total removal is preferable; for after partial removal "the tonsils grew again" and the pupil went through the same series of "sore throats every few days" as before. One teacher says that the question of total or partial removal depended, in his experience, on the skill of the operator.

Question 4. Was there any bad effect on the singing voice? If so, how manifested? Nearly all of the reporters say that no bad effect was noted. One teacher found it "hard to bring into the voice any softness or color." Another thinks the operation does not benefit "since it makes the focusing of tone impossible." "Natural conditions are changed," says one, "and the fine adjustment of the pharynx is interfered with. In some cases the voice was lowered; in others heightened from a half to a full tone. In at least one case lack of resonance was complained of, and in another the voice was weak and there was difficulty in focusing and holding the pitch.

Question 5. Do you know of any case in which the singing voice was apparently destroyed by tonsil operation? (If so, a detailed report would be most acceptable.) The majority of reporters answered *no* emphatically. One voice was damaged (not lost) "by cutting a pillar of the fauces." Another teacher complains of "careless cutting of ligaments," but does not say what was the result to the voice. Still another teacher finds that "in all cases emptiness of tone was the result, and in many cases the tonsils grew again, causing more operations." One reporter calls attention to the alleged fact that Campanini never sang after removal of his tonsils.

Question 6. What percentage of good results have you found? Fourteen teachers have seen 100 per cent. of good results; a few, only fifty per cent. Some found no effect, good or bad, and one thinks the operation "helpful in some cases, harmful in others." At least one is enthusiastic about the results, and would have every pupil operated upon regardless of the indications.

Everywhere throughout the long list of answers

there is evidence of an ignorance which ought not to exist. The vocal teacher is often out of sympathy with the laryngologist, and the laryngologist quite as surely fails to understand what the teacher is driving at.

For example: "In all of my work as a teacher, I have never had to send a student to a throat specialist. The tonsils, if there has been any difficulty, have, through correct use of the throat, voice, and breathing with the aid of proper systematic remedies, gone back to a natural, normal size, etc."

By contrast, a Chicago teacher writes: "If more singers would consult a skilled throat specialist, we should have more real singers. No matter how perfect the method, it does not count unless throat and nose conditions are normal."

Another teacher thinks that "bad tonsils can be corrected by proper habits as applied to food, air, breathing exercises, and sleep. They are an indication of a poisoned system. Removal does not touch the cause." In a personal letter a physician writes his opinion that "much tonsil trouble is caused by bad teaching."

In my own experience twenty-five singers have been tonsillectomized with uniformly good results. That is, the range has been improved a half to a full tone, and there has been no difficulty in adjusting voice placement to the new conditions. Vocal power and resonance have both been increased. In one case, that of a very large man, hemorrhage occurred four hours after operation. This was controlled by grasping the bleeding point with a special kind of artery clamp, and recovery was uneventful. There was no contraction of the fauces in this case, and his teacher declared that the improvement in vocal work was very noticeable. However, in one baritone whose course of healing was complicated by an infection of unknown origin, there seemed to be a greater tendency to attacks of acute bronchitis. Whether this was really so I cannot say, as it was necessary to rely on the testimony of an extremely introspective patient who magnified his ills whenever possible. Nevertheless, in spite of this apparently untoward result, he was glad that he had gone through the operation, and his vocal range and power were undoubtedly increased thereby.

In certain selected cases it is undoubtedly better to temporize than to operate. Every specialist of experience will know and recognize the special considerations which afford a basis for this judgment. Occasionally it is better to do a tonsillotomy (partial removal) and follow the procedure at a later date by treatment of the cryptic stumps by applying a bead of chromic acid deep into the interior, or using the electrocautery point as already mentioned. Undoubtedly, the small, cheesy tonsil should be removed *en masse*, as nothing is to be gained by simply puttering with it. The sooner it is out the better.

Dr. G. Hudson Makuen, of Philadelphia, whose work on voice and speech defects is known the world over, writes me that "it is safe to say that no tonsillectomy has ever injured the voice when the operation was really indicated and properly performed, but that many voices have been injured by ill advised and careless operations I have no doubt whatsoever."

Dr. J. Solis Cohen, of Philadelphia, thinks that "where hypertrophied tonsils impair the singing voice, improvement should follow operation. Where the contour of the tonsil is essential to the timbre of the voice, interference will impair it."

Finally, Dr. Justus Matthews, of the Mayo clinic, Rochester, Minnesota, who has performed an enormous number of tonsil operations, answered the questionnaire and added the following opinion: "I believe that most of the cases (of loss of singing voice following tonsil removal) are purely imaginary and are due to some other cause. However, I have seen several cases and feel certain that the cause is to be found in the cutting of the nerves."

CONCLUSIONS.

1. An analysis of 5,000 tonsil operations in singers shows that in the hands of skilled operators there need be no special fear of bad results.

2. It is the consensus that bad results are most often due to cicatricial contractions occurring from careless dissection or from neglected aftertreatment.

3. Pain in the tonsillar region, neck, and larynx, is probably due to section of some of the larger branches of the glossopharyngeal nerve (Justus Matthews).

4. Loss of singing voice after tonsillectomy might be due to a nerve lesion, but is probably due to adhesions and cicatricial formations in the fauces.

5. Loss of singing voice occurs very rarely after tonsillectomy. Impaired voice is possible, but most cases show an increased range of from one half to a full tone.

6. The singer's problem is a very special one, and no laryngologist should undertake to operate on these patients unless he has some knowledge of the art of singing.

7. At operation the greatest care and skill must be exercised in securing a clean, free dissection. Injury to the tissues surrounding the tonsil may prove disastrous.

8. Postoperative care is of special importance. The patient should be seen daily until full healing occurs.

THE EXPERIMENTAL PATHOLOGY OF GOITRE.*

By Ernest Zueblin, M. D.,
Baltimore,
Professor of Experimental and Clinical Medicine, University of Maryland.

A review of the literature on the etiological causes of goitre reveals a great variety of influences which according to the different authors are important. Owing to the short time available for discussion, only the most important can be briefly mentioned. According to Heydenreich, we must consider, 1, exogenous, and, 2, endogenous causes.

Among the exogenous factors, conditions of the *atmospheric air*, lack of sunshine, humidity, lack of oxygen or excess of oxygen; astronomical influences, such as the different phases of the moon, changes in the distribution of electricity and of heat

*Read at the seventeenth annual meeting of the American Therapeutic Society, Detroit, Mich., June 9, 1916.

have been mentioned; although formerly the social and economic position and the hygienic surroundings of the patient have been emphasized. Many exceptions to this rule could be named which tend to show that goitre is encountered all over the world, and is not restricted to a certain race nor to certain social and hygienic surroundings.

Among the many theories advanced and disputed there are four which are accepted as possible: 1. The soil; 2, the water supply; 3, microbic infection; 4, toxins. A considerable amount of literature has been accumulating; the majority of the contributions have been made by European authors; a small percentage by American writers.

1. I allude briefly to the geological strata to which a goitrogenous influence is ascribed. It may not be necessary to cite a long list of contributors who, basing their assertions upon a comparison of geological formations with statistics and personal investigation, are in favor of the soil theory. Views which admitted the influences of altitude, humidity, amount of sunshine, on the frequency of goitre, can no longer be accepted.

To McClelland's first and thorough study (1835) several contributions from France, Spain, Italy, Germany, Switzerland, and Norway have been added; they all confirm the opinion that goitre is to be encountered on soil composed of marine sediments, particularly from those formed during the paleozoic, the triassic, and tertiary periods. Free from goitre is the soil formed by the eruptive rocks, the crystalline rocks of the archaic period, the sediment of the cretaceous and the quaternary sea, as well as all deposits from sweet water.

Since Hirsch, in 1881, called attention to the influence of geological strata upon goitre formation, H. Bircher in Switzerland, Johanessen in Norway, Höfler in Bavaria, Sormani Tommasi Crudeli in Italy, Mayer in France, Kocher and Lorenz in Switzerland, and many others have added further proof of the relationship.

In the United States different epidemics of goitre have been described by Munson among the Indians; by Springle in Montreal; by Morris in Hambleden; by Dock in Michigan; by Ashmead in Pennsylvania; by Holder in Montana; in Dakota, along the Mississippi River; in the Rocky Mountains by Marine; in the region of the great lakes; in Montreal, Buffalo, Detroit, Cleveland, Lake Erie, Portland, Oregon, and in Seattle, but so far little attention has been paid to the geological formation of the soil upon which these epidemics occurred. The possibility cannot be denied that further inquiry concerning these factors would furnish interesting information.

2. The second theory, which renders the water supply responsible for the production of goitre, has been admitted by many authors. Different facts were adduced in support of such an argument; for instance, that a change in the water supply reduced the number of goitres, that by the use of goitrous water a goitre could be produced in formerly normal human beings as well as in animals; that rain water does not produce the disease. Such an influence being admitted, the experimental reproduction of goitre by furnishing water to animals and human beings was required, as suggested by the following experiments:

Klebs obtained goitre by giving a dog goitrogenous water and injecting it into the thyroid gland. Lustig and Carle in their report to the Tenth International Congress, in Berlin, referred to positive results in a horse and three dogs supplied with goitrogenous water. The direct implantation of goitre into a healthy thyroid gland, the injection of goitre extract, the feeding of feces from goitrous animals to healthy animals, however, were all negative as observed by Grassi and Munaron and Kolle. The human experiments of MacCarreson (1911) in Gilgit on thirty-three patients are of interest. He found that the fresh sediment of goitrogenous water produced goitre in six cases out of the thirty-three; no enlargement was obtained with the boiled sediment in twenty-three instances and in seven who were kept on filtered water alone. E. Bircher's observations on white rats at the clinic in Basel are of interest. After six to nine months of feeding with goitrogenous water, not only macroscopically but histologically goitre was produced. In the course of further experiments it was found that the fresher the water and the shorter the distance of the spring, more certainly were the animals exposed to goitre. Conversely, a long transportation, boiling, and filtration of the goitrogenous water reduced the positive results.

Confirmatory facts were obtained by Wilms in Heidelberg, Lobenhofer, Eiselsberg, Breitner, Schlagenhaufer, Wagner van Jauregg in Austria, Répin and Roussy in Maurienne, France. In all instances of macroscopic enlargement the characteristic histological changes were encountered. In such experimental tests it must be remembered that not only individual susceptibility according to the species of animal chosen is a deciding factor, but also that the water should be fresh, since transportation results in speedy loss of its goitrogenous properties.

These experimental results, however, were not generally accepted. In a careful canvass of the goitre problem in Switzerland, Dieterle, Hirschfeld, Klinger, and Montigel, reached the conclusion that goitre does not necessarily depend upon the water supply, nor upon the geological nature of the soil in the region in which the disease is encountered.

3. The microbic origin of the disease was suspected by several authors, among whom Virchow and Lücke are mentioned. First, Klebs found Diatomea navicula and Monades in the goitrogenous waters. H. Bircher, later Maggi, confirmed the statements of Klebs, a further species, Encyonema auerwaldi being added to the list of organisms found in such waters, while Tavel could not report any definite results by the infection of dogs and rabbits with such organisms. Jaboulay's findings of staphylococci in freshly extirpated goitres, and his later assertions of Sporozoon myxosporidium as the cause of metastatic and malignant forms of goitres are of interest. Such findings were confirmed by Rivière. Different cultures inoculated into mules and dogs, even by injection into the thyroid gland itself, however, remained absolutely negative. Bérard and Thévenat found staphylococci in six cases

out of ten goitres, four being sterile; a mere hyperplasia, but no goitre was obtained. Whether fluorescent bacteria can produce goitre, an opinion advanced by Proca, remains doubtful. Kolbe's search for protozoa, bacteria, and antigens was negative. No immunity was obtained by injecting goitrous tissues, goitre extract, blood, and fecal extract obtained from goitrous patients into animals.

Feeding goitre tissue, intravenous injection, direct transplantation gave negative results. Goitrogenous water injected intravenously for months into rabbits produced no specific rabbit serum. Complement fixation with rabbit blood and goitrogenous water as antigen, however, was positive, also Weichhardt's epiphanin reaction (Schittenhelm and Weichhardt). The discovery of Chagas in Minas-Geraes, of trypanosomata in goitrous patients as the cause of goitre symptoms is of interest. The parasitic origin of goitre is far from being generally accepted and the argument is still pending.

MacCameron encountered amebas in the feces of his goitre patients; he was successful in the cultivation of a bacterium akin to the colon group, and resorted to the use of an autogenous vaccine leading to a reduction in the size of thirty-three goitres. This author's hypothesis of a neutralizing action of the thyroid gland upon intestinal toxins may be mentioned. Such a possibility is admitted by Kutschera von Aichbergen, McGarrison, and R. Farrant. Sazuki succeeded in the experimental reproduction of goitres in rats by feeding and injecting them with feces from goitrous rats.

4. As already mentioned, in the toxin theory of goitre the following subdivision must be remembered:

A. Inorganic toxins caused (*a*), by lack of certain substances; (*b*), by an excess of certain substances.

B. Organic toxins represented by (*a*), an organic ferment; (*b*), by colloid substances.

A. (*a*). The lack of oxygen as advanced by Boussingault; the lack of sodium chloride (Demartin, Eulenberg, Schwalbe), lack of phosphate (Ackermann), lack of iodine, and of bromine (Chatin, Marchand, Fourcault, Maffoni, Provost) are theories of historical interest. So many exceptions were found, that this explanation fails to be satisfactory.

A. (*b*). The excess of the following substances: Lime, plaster of Paris, magnesia, soluble chlorides, dissolved carbon, sulphide of iron and copper, of the fluorine compounds (Maumené), of the silicates, and of the mercury compounds can no longer be held responsible for goitre.

B. (*a*). Kocher, investigating organic ferments as causes of goitre, had already reached the conclusion that the disease must have a certain etiological relation to certain admixtures and impurities in the soil, which must be of an organic or organized nature of short life, since the disease increased only as long as the suspected water was used.

Wilms advanced the following theory, based upon the experiments of Bircher: He admitted as cause of goitre a toxic substance, not of parasitic nature, but containing the dried animal residues found in the geological layers characteristic of the periods of marine submersion. The water passing through the layers becomes polluted by these substances and goitrogenous. The following reason for such a theory may be mentioned. Goitrogenous toxin passes the Berkefeld filters; it is inactivated by heating to 70° C. (158° F.), just as the albumins lose their effect. The goitrogenous toxin does not survive concentration by the vacuum method, while marked deposits of sodium chloride are formed. It is possible that the lime compounds favor the precipitation of the toxin and so explain the contention that in certain lime districts, formed in the Jurassic and Cretaceous periods, goitre is not found. Sazuki's animal experiments were made with the following substances:

TABLE I.

	Animals	Administered	Result
Boiled rice contaminated with feces from goitrous rats	Rats	Feeding subcutaneous	Diffuse moderate enlargement of thyroid gland
Fish deteriorated		Feeding	Negative, quick fatal results, general abnormal development
Deteriorated meat		Feeding	Negative
Sweetbread of veal		Feeding	Negative
Cadaverin		Subcutaneous	Negative
Tyrosin		Subcutaneous	Negative
Acetonitril		Subcutaneous	Negative
Pot. iodide + rat feces		Feeding	Negative
Iodothyrin + rat feces powdered		Feeding	Negative

Such experiments show that organic poisons are not responsible for goitre, while feeding and injection of feces produce goitrous changes (already mentioned by MacCameron). Iodine compounds have an inhibiting influence upon goitre.

B. (*b*). The goitrogenous substance is supposed to be a colloid; this is the theory of Bircher. He demonstrated that the goitrogenous qualities of water are unchanged by filtration through paper and the Berkefeld filter, and that the filter residue fed to animals is innocuous. He gives the table of his experiments. (Table II, page 1189.)

Space unfortunately forbids me either to enter into the complex theories of Bircher about the goitre toxin which he describes as emulsoid and lyophil hydrosol, or to discuss the colloid nature, the crystallized appearance, or the possible absorption of toxin, by certain geological layers. Bircher does not discard entirely the possibility of a microorganism retained in certain layers, furnishing the toxin. Histologically Bircher's experimental goitres are represented by two types, namely, nodular adenomatous forms and parenchymatous hyperplastic processes, with desquamation and degeneration of the follicular elements also encountered in human species. It must be remembered that the feeding of the dialyzing membrane itself, and of the residue led to most pronounced degeneration of the epithelial cells and their nuclei.

The radioactive quality of goitrogenous waters is discussed by Répin. The complex process, how water becomes goitrogenous, is a problem of great scientific interest, but cannot be discussed here. Répin confirms the opinions of Bircher showing

how quickly a goitrogenous water can lose its pathogenic qualities by long transportation, careless handling, etc.

Vicard's theory of the importance of the calcium ions in the cellular metabolism by their action as an excitant upon the thyroid gland, leading to goitrous degeneration and hypothyroidism, to changes in the metabolism of nitrogen must be followed with interest, although more time and experiments will be required before this theory can replace other theories of the etiology of goitre.

In addition to the preceding opinions, we must be considered; also age, since we know that at the age of puberty goitre is most frequent, suggesting the influence of an internal secretion through the activity of the sex glands. It is a well known fact that females are more frequently affected by goitre than males; frequent menstruation, conception, and parturition have undoubtedly an influence upon the size and function of the thyroid gland.

Among the laity other views are expressed about the endogenous causes of goitre, such as repeated congestion of the head and vessels of the neck in carrying heavy loads; direct or indirect pressure

TABLE II.

Spring		Treated	Animals	Results
Rupperswil water	Old spring	Genuine		Strong positive
Rupperswil water	Old spring	Filtered Berkefeld	Rats fed during 18 months	Strong positive
Aarau water	Old spring	Genuine		Strong positive
Rupperswil water		Genuine		Disturbance of growth (epiphyseal line) moderate enlargement of thyroid gland
Muschel Kalk water				Strong positive
Asp water				Strong positive
Hundwil water		After long transportation		Negative
Aucnstein water goitre free		Allowed to pass through gravel of Rupperswil water		Negative Experiments not lasting long enough
Goitrogenous water		Allowed to pass through Jurassic-Malm	Given 5-8 months after 10-14 months filter became permeable	No goitre Slow goitre formation
Goitrogenous water Goitrogenous water		Dialyzed Inner cell Outer cell		No goitre Positive goitre

also mention contact infection as a possible cause of goitre. Such an hypothesis has been brought forward by Grassi and Munaron; Kutschera von Aichbergen also maintains a similar standpoint.

Taussig, after his observations in Bosnia, concluded that immigrants affected with goitre transmitted the disease to others. Since Flinker's studies of that problem, refuting the theories of Kutschera and Taussig, it must be conceded that in his instances an intimate relation to cretins was observed without immediate contact infection.

Endogenous causes of goitre. Heredity and disposition play no doubt a role in endemic cases of goitre, while changes in the internal secretion must be thought of, particularly in sporadic, to a lesser extent in endemic goitre. The suprarenal bodies, ovaries, pancreas, etc., no doubt influence one another in their functions, and a diseased condition of these organs must have a disturbing influence upon the general functional equilibrium. As regards the influence of heredity, opinions differ considerably. Italian authors, Cerletti and Perusini, for example, consider heredity the most important factor, while Bircher admits heredity to be a predisposing influence. Weichhardt and Schittenhelm, in a careful study of families with goitre, have refuted the general opinion that people immigrating from goitre immune countries into districts where goitre prevails will not be affected by the disease. Beside hereditary influences, individual predisposition must upon the vessels of the neck, from cardiovascular and respiratory disturbances, or violent physical exercise. Whether these factors aid directly or indirectly in the production of goitre remains still open for further investigation. Although the presence of a goitre heart is closely connected with goitre etiology, I must refrain from further discussion of this important point, as space will permit only a short review of the past and present ideas accepted and refuted as to goitre etiology.

The general impression gained from the present knowledge of the goitre problem is that we have not yet reached a satisfactory understanding of it. At a time when American investigation has contributed so much to medical science, a nationwide investigation into goitre etiology would certainly be desirable. Further contributions on the possible influence of geological strata, of colloid substances, of the water supply, of altered internal secretion, and of other possibilities would certainly help our understanding of this complex problem.

Latrobe Apartments.

The White Blood Cells after the Removal of the Thymus.—A. E. Selinow (*Roussky Vratch*, July 9, 1916) states that he determined experimentally the effect of the removal of the thymus on the leucocytes. His experiments on guineapigs showed a slight and temporary increase in number.

INFANTILE PARALYSIS TREATED WITH IMMUNE SERUM.

By Orlando H. Petty, M. D.,
Philadelphia.
Instructor in Medicine, Jefferson Medical College; Pathologist, Germantown and St. Timothy's Hospitals.

In estimating the therapeutic value of immune serum in poliomyelitis, certain facts must be considered. There is in all cases of disease an indeterminate and unmeasurable force, *Vis medicatrix naturæ*. This force must be acknowledged as an aid in all therapeutic measures, and it must be recognized in connection with the administration of immune serum in poliomyelitis, whether the serum is administered intravenously, intramuscularly, or by the subdural route. It is only through this force, in many of the practically untreated cases of poliomyelitis, that the maintenance of life and the restoration of power can be explained.

When the serum is administered by the subdural route, we must not lose sight of the fact that the simple withdrawal of spinal fluid in meningeal inflammation is followed by an amelioration of some of the most prominent symptoms; the temperature drops temporarily, the respiratory rate is lowered, irritability or sopor is lessened, and not infrequently, as in Case III of this series, lost function is to a great degree restored.

From a study of eleven cases of poliomyelitis treated in private homes with immune human serum administered by the subdural route since August, 1916, and in which no unfavorable symptoms were noted, I would draw the following conclusions:

Immune serum, to be of curative or prophylactic value, must be administered early, preferably in the preparalytic stage, preferably by the subdural route.

Subdural administration should always be by gravity, less serum in amount being introduced than the total amount of fluid withdrawn, except in rare instances where the pressure is so low that not more than one or two c. c. will flow through the needle. It must be remembered that the withdrawal of ten to twenty c. c. of spinal fluid will reduce the pressure in children from ten to fifteen mm. Hg. The dose in children probably should not exceed ten c. c.

Many adults have a cellular immunity, and it is probable that the immune qualities of adults, who have had an attack of poliomyelitis during infancy, is of this type. A serum, not inactivated, from those who had an attack not over ten years previously, would be the one of choice.

Case I. M. M., aged three years, serum administration twenty-six hours after parents noticed child to be sick. There was at this time slight ocular and evident respiratory disturbance. Within a few hours there was loss of power in right deltoid, but the respiratory disturbance cleared up only to reappear about twenty hours after injection of serum. Second dose of serum, six c. c., was then given, followed within a few hours by a drop of two degrees in temperature, regular respirations, and finally recovery with slight ocular and right deltoid paralysis.

Case II. D. M., age three and a half years. Serum administered within forty-eight hours of beginning of attack. Patient had marked weakness of left leg, which disappeared six hours after receiving serum. The temperature fell from 103° to 99.2° F., and child became bright and cheerful. Fourteen hours after first dose of serum, child had a marked irregularity of respiration, and died just seventeen hours after first dose.

Case III. M. S., aged two years, spinal puncture fourth day of disease. Both arms and legs paralyzed; breathing irregular; within twenty minutes of the withdrawal of thirty-five c. c. of spinal fluid, the child could use its arms and move the legs. Paralysis returned within a few hours, so five c. c. of immune serum were administered, and were followed by so much improvement that the patient was considered out of danger for two and a half days, when it suddenly manifested respiratory failure and died.

Case IV. L. M., aged five years, sick eighteen hours when five c. c. of serum were administered in the preparalytic stage; this was followed by a reduction of temperature and the lessening of irritability and pain. Ten hours later, there was difficulty in deglutition, ocular and facial paralysis, followed later by respiratory disturbance and left leg involvement. This increased involvement indicated the introduction of more serum, which was followed within four hours by a disappearance of all paralysis, except in eyes and left leg. Patient recovered with no evident paralysis, except after overexertion, when the left leg dragged and one eye turned inward.

Case V. N. O., aged nine years, sick thirty hours. Both legs involved and marked meningeal symptoms, when five c. c. of serum were administered. Six hours after serum was given, the temperature had dropped from 103.6° to 100° F., the child could move its legs and was much brighter. A second dose of serum was given, followed by no marked improvement. Eight weeks later, child could walk unaided, but there was a noticeable loss of power.

Case VI. O. P., aged four months, sick six days, temperature 104° F., paralysis of arms and legs and left rectus, and respiratory disturbance. Five hours after the administration of serum, temperature was 99.4° F., and the patient could use arms. The second dose within twenty-four hours showed no improvement. The child recovered with both legs paralyzed.

Case VII. P. R., aged three months, sick thirty-eight hours, respiratory disturbance, both legs and abdominal muscles involved. Infant was cyanotic, but parents insisted upon the use of serum, the child dying just six hours afterward.

Case VIII. R. S., aged three and a half years; ten c. c. of serum administered thirty-six hours after initial symptoms, the respiratory centre showing the only involvement, followed by slight improvement. The second dose of fifteen c. c. did not seem to change conditions, there being a gradual increase of symptoms, the child dying in the fourth day of the disease.

Case IX. S. T., aged seventeen years. Thirty hours after the beginning of the attack there was ocular and facial paralysis, when six c. c. of serum were administered. Within five hours paralysis had disappeared, temperature lowered, all of these symptoms returning in twenty hours. Twelve c. c. of serum were administered, the temperature soon reaching normal and the paralysis disappearing permanently.

Case X. T. V., aged five years, sick thirty-four hours with paralysis of both legs, and unconscious, when five c. c. of serum were administered, followed by slight improvement. Second dose, within twenty-four hours, when temperature of 102.2° F. fell to 99° F., child making slow, but almost complete recovery.

Case XI. W. A., aged five years, serum administered in the preparalytic stage, sixteen hours after beginning of disease. Temperature and respiration improved for a few hours only, when both legs were attacked and there was some respiratory involvement. More serum was given, and the respiratory trouble disappeared; the temperature fell 2.5° F., there being a slow, yet steady increase of power in the legs.

In all the foregoing cases, serum was administered subdurally, and the spinal fluid carefully studied.

6215 Ridge Avenue.

Three New Signs in Sciatica.—D. de Sandro (*Revista Critica di Clinica Medica*, October 21, 1916) names three new diagnostic signs in sciatica, gluteal pain over the suprapopliteal point, external rotation of the leg, and dorsal flexion of the toes.

COMPULSORY HEALTH INSURANCE.*

From the Point of View of the General Practitioner,

By Eden V. Delphey, M. D.,
New York.

The subject of compulsory health insurance is one of the most important which has ever come before the medical profession. Its adoption will revolutionize the general practice of medicine so that instead of being an individualist, the physician will be merely a cog in a great medical machine. Are we ready thus to lose our professional identity? Will it not be better to make haste slowly, and approach the matter with a due consideration of the difficulty of the problem? Injudicious interference with the body politic is as likely to cause damage as undue interference with the body physical, and the result is much more likely to be a distortion than a development. More social movements have been wrecked on the reef of undue haste than in any other way. Great and desirable social reforms are the result, not of the will of this or that person, but of a gradual system of sane and natural evolution; and thus, and thus only, do we get that careful adjustment to conditions which results in a permanent, stable, and healthy progressive system. All evolution proves this. The development of the highest specimen of the animal kingdom, man, was not completed in a day. What we may decide today to be best, we will know three months from now to be very imperfect; and the same result will obtain in six months and a year later. Therefore it will be much better to delay action on this matter until we have had sufficient time to study the subject thoroughly, and to come to certain definite conclusions as to just what kind of a health insurance law will be best for all concerned: the employee, the employer, the physician, and the State. Although all these four parties are concerned, the physician is the one who is most vitally interested, and in a position to lose the most unless a proper law is enacted.

In order to learn whether, and to what extent the physicians in this country have studied compulsory health insurance, I sent the following letter to the secretaries of all of the State medical societies in the United States.

New York, *November 2*, 1916.

My Dear Doctor:

I am preparing a paper on the subject of Health Insurance to be read at a mass meeting of the combined County Medical Societies of the lower part of this state and will be very grateful to you if you will kindly furnish me with the following information:

1. Has the matter of compulsory, or any other kind of health insurance ever been formally brought before your State Society?
2. Has your State Society ever taken any action, either pro or con, regarding it?
3. Did your State Society instruct its delegates to the American Medical Association—annual meeting held at Detroit, June 12-16, 1916—either pro or con, regarding health insurance?
4. Do you know what is the sentiment of the medical profession in your state regarding health insurance?
5. Do you consider the second "tentative draft" issued by the A. A. L. L. to be just and fair to the medical profession?
6. What do you consider to be the best form of health insurance, providing some form of health insurance is inevitable?
7. Do you think that inasmuch as the State must pay the expense eventually, that it would be better to have the State take over the matter of health insurance, and insure every man, woman, and child, earning under a specified sum per annum, whether they paid any assessments or not, on the same principle that the State furnishes common school education? Would this plan be better, simpler, and cheaper than the various plans so far promulgated?

Very sincerely yours,
Eden V. Delphey, M.D.

The replies may be summed up as follows:

1. Yes	9	5. Yes	3
No	23	No	5
2. Favorable	2	Doubtful	1
Committees	6	Don't know	23
No	24	6. By employer, employee and State.	2
3. No	32	Like compensation insurance	1
4. Favorable	2	Free choice, good compensation	1
Unfavorable	4	Don't know	28
Doubtful	1	7. Yes	4
Subjudice	1	No	3
Don't know	24	Probably	2
		Don't know	23

The foregoing indicates that the physicians all over this country with few exceptions have not studied the subject sufficiently to be able to come to any just and proper conclusions regarding the various plans and provisions for incorporation into a health insurance law. We are not yet ready to say just what is the best law to enact, and we believe that we should study the subject carefully for some time to come before we arrive at a proper solution of the problem.

The great mass of the general practitioners of medicine are in severe straits, as indicated in an editorial article in the *New York State Journal of Medicine* for August, 1915, as follows: "Fifty per cent. of the general practitioners of medicine of New York city at present find it difficult to meet their current expenses, economize as they will." The truth of this statement may be questioned, but fifteen months have elapsed since its publication and so far I have seen no contradiction of its verity in any of the medical or lay journals. But will the establishment of a compulsory health insurance law improve this condition? Will it not be jumping out of the frying pan into the fire? In my humble opinion, it certainly will be unless the medical profession awakes to the danger which is besetting it, and takes proper and adequate measures to protect itself. Since our professional financial life is assailed, we must fight for our rights just as our English brethren did when they were compelled to do so. We must disprove the idea quoted by A. S. Comyns Carr in his work on *National Insurance* (Health Insurance): "The community has been accustomed to regard medical men as amiable weaklings in business matters, easily gulled by piteous tales, or flattering remarks about the magnanimity of the profession."

This question is *not* an altruistic one. It is not a question of medically looking after the poor unfortunate and needy sick; because according to the provisions of the health insurance bills so far proposed it is a serious question whether the very

*Read before the Committee on Medical Economics of the Medical Society of the State of New York, at a meeting held at the New York Academy of Medicine, November 23, 1916.

poor are not entirely or almost entirely left out of consideration, since there are a large number of persons who will not be able to pay their assessments in order to be entitled to the benefits of the insurance, and the extension for nonpayment is but one week for four weeks of paid up assessments. Every health insurance plan so far advocated includes within its scope only wage earners who make less than a specified sum a year and who are able to pay their share of the cost of the insurance. Such plans include the steady workers, a picked group, and not those who most need the insurance. The lot of the casual laborer is grievously hard. Many cannot spare the amount necessary to pay the premiums continuously in order to deserve the benefits, because a large number of workingmen's families live upon a very narrow margin. It is an axiom that the less a man earns a day the fewer days he works. Therefore those who are unable to pay the assessments on account of previous illness, general incompetency, shiftlessness, alcoholism, or from any other disabling condition, will be left to the tender charity of the general practitioners as heretofore.

If we must have health insurance, to get the best results the State or Federal Government should insure every man, woman, and child whether they pay any part of the cost or not on the same ground and for the same purpose that the State furnishes free schooling, free water and free fire, and police protection. This obviously does not include a monetary sick benefit. If that is desired, it can easily be arranged that only those who pay assessments shall be entitled to share therein, but not the others; or the monetary benefits can be left to the benefit societies now in existence. Universal health insurance is the only way to reach those who are most in need of it. In any case, the best results will be obtained by having the sick insurance plan instituted, operated, and managed by the State and from a State fund. Under the Compensation Law the State fund is insuring the employers for twenty per cent. less than do the casualty insurance companies, and there is no reason why a State fund cannot insure under a health insurance law quite as economically. If necessary, the machinery proposed for some of these various schemes might be used in part.

All the proposed plans for compulsory health insurance institute a middle man between the patient and the physician, and the experience of many competent observers is that such an arrangement tends to debase the quality of the medical service as well as the remuneration of the physician who does the work. Unless there is provision for *collective bargaining by the physician as well as by the patient,* the insurance carrier will try to grind down the panel physician to the lowest possible pecuniary point, as is now done in "lodge practice," with the result that the medical service will be very inefficient. The farmer finds it is to his advantage to take good care of his horses and implements, the mechanic of his tools, the manufacturer of his machinery, and nowadays the employer of his employees, in order to get the best results and to make the most money. Therefore, under any scheme of health insurance whatever, and under any condition of medical service, unless the physician is sufficiently compensated so that he can be well housed, well clothed, and well fed, he cannot do his best work, and the sick insured person will suffer.

Whether we are in favor of compulsory health insurance, whether we are opposed to it, or whether we insist that we have more time to study the subject carefully in order to determine what is best, not only for ourselves but for the wage earner also, there are certain fundamental propositions which we should insist that the promoters and promulgators insert in every health insurance bill which they introduce into the legislatures, as follows:

1. Adequate and proper representation on the commission, councils, and on all other boards having to do with medical matters.
2. The formation of lists or panels of physicians, on which list or panel every legally qualified medical practitioner shall have the right to have his name recorded.
3. The sick insured wage earner shall have the right to choose any panel physician on any panel to attend and treat him, subject only to the acceptance of the patient by the physician.
4. The insurance carriers shall make all contracts for medical attendance and treatment only with organizations composed of the physicians of one or more panels in an insurance district, to which organization every panel physician must belong.
5. Impartial referees—medical officers—appointed by the Commission and paid by the State, who shall decide when an insured wage earner is incapacitated by illness, when he has recovered and can return to his work, whether he shall go to a hospital or remain at home. Also to determine the character and efficiency of the medical service, and act as experts to the commission and councils.

There are other matters which will come up for determination, among which are:

1. The maximum number of patients which any one physician can properly attend and treat.
2. The method of compensation to the physician, whether it shall be by a "capitation fee," a "visitation fee," or a "capitation fee" plus a small "visitation fee," to prevent trivial and unnecessary calls.
3. The arrangement for treatment of the sick wage earners by specialists, consultants, attendance by nurses, and for laboratory service.
4. The determination of the status and relation of the panel physician to the hospital caring for the sick wage earners, whether these hospitals now exist or are to be created.

The method of remuneration by "capitation, etc.," will be determined in the contract with each panel, but the others can well be left to the direction of the commission, as they are largely matters of administration; but the five fundamental propositions must be included in the law. The one which we must especially insist on, for it is the crux of the whole situation, is:

Collective bargaining by the physician as well as by the patient.

The following plan is suggested for the organization of commissions, councils, etc., to apply the compulsory health insurance law so far as it affects medical men:

1. Temporary Commission (4 members) appointed by the Governor of the State
   Chairman, representing the State.
   Member, representing the Employer.
   Member, representing the Employee.
   Member representing the Physicians from nominations made by the Medical Society of the State of New York; also must be a physician in general practice at the time that the law was enacted.

2. Permanent Commission (5 members) appointed by the Governor of the State.
   - Chairman, representing the State.
   - Member, representing the Employer from nominations made by them.
   - Member, representing the Employee from nominations made by them.
   - Member, representing the Physicians from nominations made by panels.
   - The State Commissioner of Health ex officio, who shall have a voice and vote in matters of sanitation and public health only.
3. Supreme Council, appointed by the Commission (7 members).
   - Chairman, representing the State.
   - 2 Members representing the Employers, from nominations, etc.
   - 2 Members representing the Employees, from nominations, etc.
   - 2 Members representing the Physicians, from nominations, etc.
4. Superior Councils (7 members each), (3 to 10 in the State) appointed by the Commission.
   - Chairman representing the State.
   - 2 Members representing the Employers, from nominations, etc.
   - 2 Members representing the Employees, from nominations, etc.
   - 2 Members representing the Physicians, from nominations, etc.
5. Panels of physicians in each insurance district.

The panel physicians shall organize and may, with the consent of the commission, perfect a complete State organization in order to weld themselves together for the purpose of better carrying out the purposes of the law.

All purely medical questions decided by the referees may be appealed to the panel, the superior council, the supreme council in succession, and when and if the decisions of the supreme council are approved by the commission, the result shall be final.

In all disputes between the panel physicians and the insurance carriers, appealed to the councils and the commission, the physician in the councils and commission shall each have two votes in order to equalize the voting power of the disputants.

The councils shall have the consideration of the disputes appealed to them; the approval of regulations suggested by the insurance carriers or the panel physicians.

The members of the commission shall have general administrative control and direction of the entire enforcement of the law; they shall be appointed for varying lengths of service so that the term of no two of them shall expire at the same time.

362 West Fifty-seventh Street.

GASTRIC AND DUODENAL ULCERS.

Diagnosis and Treatment,

By Samuel Weiss, M. D.,
New York.

It is now well known that the symptoms of gastric and duodenal ulcer are so nearly alike that only exceptionally can they be differentiated. It is evident that all medical men, surgeons as well as physicians, until within the last five or six years, were ignorant of much that is now known concerning peptic ulcers, especially duodenal ulcers.

The most striking feature in the great mass of statistics concerning peptic ulcers which has accumulated within the last six years, is the diversity of the figures showing the relative proportions of all such cases in the two sexes, and the ratio of duodenal to gastric ulcers. Reports of many thousands of cases seem to indicate that until within a recent date gastric ulcer was most common in women, and duodenal ulcer comparatively rare in both sexes. In the large series of cases recently reported in this country, so far as I have seen, a decided majority of peptic ulcers have been in men.

Kehr, of Germany, between 1904 and 1912 operated in 954 cases for cholelithiasis and found duodenal ulcer twenty-nine times in ninety-four operations that involved the duodenum. Only three of the twenty-nine were in women, while only one of sixteen operations for gastric ulcer was in a male.

A somewhat comprehensive study of the recent literature of gastric ulcer was begun by me while I was under the impression that the duodenal variety was more serious and dangerous, as well as more prevalent than the gastric, and that, therefore, it was highly important to make the differential diagnosis between the two varieties in order that when the presence of duodenal ulcer was made reasonably certain, there might be an earlier resort to surgery. But Mayo (*Annals of Surgery,* September, 1911) says: "A differential diagnosis between duodenal and gastric ulcer can be usually made without difficulty, but it is not essential." Moynihan, in his book, *Duodenal Ulcer,* is still more emphatic in asserting that this diagnosis is easy, and insists that it can be made from the history alone.

American and English statistics have proved that duodenal ulcer is certainly more prevalent than gastric ulcer, and more careful investigation leads to the conclusion that it is only in advanced stages of the unrecognized and neglected cases that duodenal ulcer is the more dangerous. In fact, 1,725 cases of peptic ulcer, from the report of Smithies, shows 1,225 cases of duodenal ulcer and 500 of gastric ulcer, or a proportion of about two and a half to one in favor of the duodenal ulcer, which is contrary to our previous impression.

The authorities now, with few exceptions, agree that in peptic ulcer, wherever situated, the antecedent, often associated, and probably causative hyperchlorhydria is generally curable at first by rest and medical treatment with the help of appropriate diet. Hence, the importance of an early diagnosis.

SYMPTOMS OF PEPTIC ULCER.

The peptic ulcer is usually single. Kemp states that the proportion is about eighty per cent. It is usually round or oval and funnel shaped and is of variable depth. The acute ulcer is usually small, punched out, with clean cut edges and a smooth floor, with no thickening of the peritoneal coat. The chronic ulcer is usually of large size, with calloused margins, and is often so indurated that if situated at the pylorus, it may, on palpation, feel like a tumor. Some cases present typical symptoms, when diagnosis is easy, other patients suffer apparently from a simple hyperchlorhydria, with no special symptoms pointing to ulcer, while in others the condition may be latent.

The most frequent symptoms are pain and a sensitive area in the epigastrium, hyperchlorhydria, the

vomiting of food, gastric juice, blood, or altered blood. In the typical case, the patient complains of actual pain in the epigastrium, which is cramplike, cutting, or boring in character. It usually begins anteriorly and radiates along the sternum or around both sides of the body, as low as the sacrum or as high as the left shoulder. The pain seldom occurs after swallowing food, but comes on usually from one half hour to four hours after eating.

The most striking clinical feature of the disease is comprised in the term, periodicity. By this is meant that discomfort occurs in spells or attacks and between such periods there is usually fairly good gastric health.

This epigastralgia occurring at a definite time after eating is the most positive sign of gastric ulcer. Gastric hemorrhage is even less diagnostic, as it may occur also in diseases of the liver, in passive congestion, and in disturbances of the greater circulatory system. The intensity of the pain may bear some relation to the food eaten. The coarser the food, the greater the pain. After liquid foods there may be no pain. Even without gross hemorrhage, anemia not uncommonly goes hand in hand with intermittent decrease in weight.

Hemorrhage may occur very suddenly. It is present in from one third to one half of the cases. There may be no vomiting of blood, but the symptoms of hemorrhage may be present, corroborated either by tarry stools or the finding of occult blood in the stool.

Less frequent symptoms seen in the later stages, especially of duodenal ulcer, are pylorospasm, hourglass stomach, and stenosis of the pylorus or duodenum.

As regards x ray findings of gastric ulcer, much prominence is given to the help afforded by the x ray examination after bismuth meals, when interpreted by experts. The bismuth lodges in the ulcers, forming shadows over them, and they are thus rendered visible, in the stomach especially. Hourglass stomach, which is most frequently a result of ulcer, is easily seen, and in both gastric and duodenal ulcer pylorospasm; also stenosis of the duodenum or pylorus in many cases. Several writers, Moynihan and the x ray experts especially, describe the striking picture made by the abnormally rapid passage of the bismuth meal through the stomach and duodenum in the earlier course of duodenal ulcer.

In the active stage of peptic ulcer, the patient usually has a hearty appetite, often an exceptionally sharp, canine hunger, accompanied and caused by the large excess of hydrochloric acid, which produces excessive appetite and thus leads to overeating, the latter having doubtless originally been the cause of excessive secretion.

DIAGNOSIS.

The diagnosis in uncomplicated and typical cases is usually easy, and it can often be made by a careful anamnesis. If, in addition to pain we have hematemesis, melena, and hyperacidity, it is practically certain.

Gastric ulcer must be differentiated from cholelithiasis, chronic gastritis, nervous gastralgia, appendicitis, gastric or intestinal cancer, from diseases of the pancreas, from hyperchlorhydria, and lastly the duodenal from the gastric variety.

From cholelithiasis. Jaundice, which is frequently present in gallstone attacks, is rare in ulcer, except when the disease involves the duodenal papilla. Epigastralgia is paroxysmal and sporadic. It comes on suddenly after errors in diet or nervous excitement. There is no periodicty. In ulcer the pain bears a definite relation to the meals. Vomiting of food or gastric juice is common in both affections. A tense right rectus may be present in both, and the pains in cholelithiasis radiate toward the back of the right shoulder more often than in ulcer, though pain in either condition may radiate in those directions. The x ray findings are totally different in the two diseases. The most important difference, however, is in the time and manner of the appearance of the pain with relation to the meals, and this is so marked that it often suffices by itself to settle the diagnosis.

In chronic gastritis, with hematemesis, the condition of the acidity of the stomach will do much to clear up the diagnosis; the pain is usually more continuous and there is no periodicity. In nervous gastralgia there is a history of neurasthenia or hysteria, and it occurs most frequently near the menopause; the paroxysms are more frequent when the stomach is empty. There is no tenderness on pressure; in fact, the pain is usually relieved by pressure; there is no hematemesis and the health is not so much impaired.

From appendicitis. The right rectus is usually tense in appendicitis, although it is sometimes rather tense in peptic ulcer situated near the pylorus where the stomach is prolapsed, especially during the pain from ulcer in the duodenum. Except for vomiting and pain and tenderness, the symptoms of ulcer are generally absent, but in appendicitis the two latter are usually felt lower down near McBurney's point, where there is often a plainly palpable tumor, and the pain may be referred to the region around the navel.

In acute and subacute attacks there is also fever, which is absent in ulcer. The picture given by the x ray is entirely different.

From cancer. In cancer of the stomach or intestine the pain is usually constant without regard to meals, though it is slight or absent in the beginning, and when the growth is in a position where it is not exposed to much pressure or irritation, it often gives little trouble for a long time. But there are rarely any notable remissions, and no relief follows vomiting, belching, or the administration of alkalies. Even when hydrochloric acid is present, the percentage steadily decreases, and the anemia, debility, emaciation, and cachexia are progressive; in gastric ulcer the nutrition is usually fairly good; while in duodenal ulcer there may be spells of emaciation there are usually marked remissions with often long periods of decided improvement in flesh, health, and strength, and free hydrochloric acid in both kinds of ulcer is nearly always excessive during the active stage, in marked contrast to its entire absence during the last year of cancer.

William J. Stone (*American Journal of the Medical Sciences*, October, 1907) emphasizes the fact that the leucocytes are moderately increased in carcinoma, averaging from 10,000 to 15,000, a very im-

portant point in the diagnosis, the leucocytosis being of the polymorphonuclear variety.

From diseases of the pancreas. In the acute forms of pancreatitis, the violent pain, vomiting, and rapid collapse may be mistaken for the perforation of an ulcer or the rupture of an abscess elsewhere, but in either case the only hope is usually in a prompt laparotomy. In chronic pancreatitis there are often no marked symptoms, and when palpable the long transverse swelling in the epigastric region is distinctive. Diagnostic also is the absence of acute pain at definite intervals after meals, and the results of examinations of stools, which in pancreatic disease show an excess of fat, and also the undigested nuclei of meat after a Schmidt meal, while in most cases of ulcer there is only the normal amount of fat and completely digested meat. High acidity in the stomach contents during active stages of the disease would be in favor of ulcer. A positive Cammidge reaction would exclude gastric ulcer, though in the opinion of Brinton (*American Journal Gastroenterology*, June, 1911) not duodenal ulcer.

From hyperchlorhydria. Pain felt regularly two to five hours after meals, and relieved by an alkali or more food is the most urgent and frequent symptom of both hyperchlorhydria and duodenal ulcer. Though exceptionally, it may sometimes appear very soon after a meal in the latter and very late in the former. If the pain is not severe, nor accompanied by sensitive points in either the epigastrium or lower spine, by occasional bleeding, occult blood, or frequent vomiting, it is probably merely the result of an excessive secretion of hydrochloric acid, but it should be regarded as threatening ulcer and treated accordingly if it does not yield promptly to diet and alkalies. As for the severe and persistently painful cases, I am inclined to agree with Moynihan that "recurrent severe hyperchlorhydria is duodenal ulcer," but to differ very positively with him in the opinion that the knife is the only hopeful remedy.

Differential diagnosis of duodenal from gastric ulcer. Duodenal ulcer is characterized by the usually much longer period of comfort after meals, and the marked periodicity of the attacks, which often come on during periods of apparent health and are of irregular duration, from a few hours to sometimes weeks or months, during which periods the pains recur ordinarily at certain regular intervals after meals, varying from one hour to five hours, or as soon as the patient becomes hungry, often awakening him from sleep in the night. These are relieved by more food, drink, or alkalies, while in gastric ulcer the pain is relieved also by vomiting or copious belching. Bleeding is common in both varieties, but hematemesis is more frequent in gastric and melena in duodenal ulcers. Painful pressure points in duodenal ulcer are generally a little to the right of the middle line in the epigastrium as well as in the lower spine, and the pains more frequently radiate toward the right.

Some authors hold that duodenal ulcer is aggravated more than gastric ulcer by cold, damp weather. The history carefully elicited is more often significant than the symptoms and signs, and there are unquestionably cases in which only an exploratory incision will decide the diagnosis. In all such doubtful cases, however, rest and dietetic treatment should be immediately instituted unless dangerous complications are present.

PROGNOSIS.

As regards prognosis, many gastric erosions and single ulcers have a natural tendency toward healing. It is also a commonly observed fact that a given ulcer will tend to chronicity and recurrence in spite of all known methods of therapy. Pyloric stenosis, with gastric dilatation, hourglass contraction, perforation, adhesions involving other viscera, or malignant degeneration, may occur without regard to treatment. In many cases of chronic ulcer the ulcer heals, but in healing leaves complications which require surgical treatment. It is generally realized, however, that chronic ulcers, owing to their frequent recurrence, not uncommonly degenerate into malignancy.

TREATMENT.

The treatment of gastric ulcer is principally dietetic and hygienic. Post mortem examinations show that a large number of ulcers heal completely, but the process is slow and tedious, often requiring months, and in severe cases years. In the medical treatment the following are the important points:

1. Absolute rest in bed for three or four weeks.

2. A carefully and systematically regulated diet. Absolute functional rest of the stomach and upper bowel for a week or ten days, the patient being meanwhile nourished exclusively by rectal feeding, or when the patients are fairly strong I have found a complete fast for some days at first to be still more effective. Theoretically, it is better to give the stomach an entire rest, but practically this cannot be done. When stomach feeding is resumed the diet should be limited for the first week to milk given in quantities of from four to twelve or even sixteen ounces, every two to three hours, with one sixth part of lime water or vichy water. Then, by the end of two weeks, it is safe to add to the daily ration one or two raw eggs, beaten thoroughly, instead of the alkaline water. Leube's ulcer diet is at the present time highly esteemed. Later the blander preparations of beef, mutton, etc., in the form of finely chopped meat rather than broths may be substituted for part of the eggs, and prunes and vegetables may be added. Still later, mashed or baked white potatoes and the other more digestible vegetables, better chopped at first, may be allowed. But all meats are very stimulating to the gastric glands, and the amount of such foods allowed should be strictly limited.

No ulcer patient should ever be dismissed without an emphatic warning that he cannot afford to risk relapse by again eating injudiciously, including pepper, mustard, and other condiments in his fare.

3. Medicinal measures are of little value. Bismuth and nitrate of silver may be given. From ten days to two weeks bismuth subcarbonate may be given in doses of from twenty to thirty grains three or four times a day in an emulsion with water and milk. If pain should persist in spite of these measures, sufficient bicarbonate of soda should be given to neutralize the hyperacidity. Opiates should not be given, since they all stimulate the secretion of hydrochloric acid, and thus tend to aggravate peptic

ulcer. Locally, either dry heat or hot poultices should be kept over the abdomen, except in hemorrhage, and then the patient should quickly be brought under the influence of morphine. This puts the parts at rest. Ice may be applied to the epigastrium and horse serum administered.

Practically, all internists and all except a few of the more radical surgeons, now concur that rest and dietetic treatment, with the help of bismuth and alkalies as required, should certainly first be given a trial, especially in simple cases which have not been neglected for many years.

There are many cases in which a cure is not possible, although they may have received the most careful dietetic, hygienic and medicinal treatment, and whenever there is uncontrollable vomiting or hemorrhage, or evidences of perforation, stenosis, or obstruction from any cause, there should be an immediate resort to surgery.

616 Madison Avenue.

Lectures and Addresses.

ADDRESS OF WELCOME,

To the Members of the American Therapeutic Society, at the Seventeenth Annual Meeting, Detroit, Mich., June 9, 1916.

By Charles G. Jennings, M. D.,
Detroit.

Mr. President and Members of the American Therapeutic Society: I assure you that I am very much gratified at the opportunity of meeting you as a society for the first time in Detroit. It has not been my profit and pleasure to meet up to this time the members of the society as a body. It is particularly interesting from one or two points of view that the American Therapeutic Society should meet at this time in the city of Detroit—a regenerated city greeting a regenerated science.

Detroit is one of the oldest cities in the United States, and therapeutics is certainly the oldest department of medicine.

Detroit has come to the notice of everybody in recent years. When I first came here, Detroit was a quiet, unpretentious, very delightful city, but little known outside of Michigan. We were on the map up in a corner. Within a very few years there has come a remarkable knowledge of Detroit, and this knowledge has been the result of efforts within the city. We were known not very long ago for our manufacture of drugs, perhaps to some extent for manufacturing stoves, but neither of these articles of manufacture attracted very much attention. About ten or twelve years ago, a half dozen young men, the sons of three of the social and financial leaders of the city, thought that automobiles were good things. They imported into the city the Packard manufacturing plant, and organized it upon its present basis. Being men of quality, their idea was to manufacture a machine of quality, the best automobile that could be made, and from that idea have developed the great Packard works. At the same time, a man in the humbler walks of life was planning an automobile on a different idea. He was a poor man and he thought of an automobile for a poor man; the result of that idea was the great Ford factory. From these two have developed the great and remarkable industries that characterize Detroit today and that are the cause of its regeneration.

Therapeutics has regenerated because of the developments in the elmentary sciences of medicine. It was impossible to improve therapeutics when we had simply post mortem pathology; it was impossible to improve therapeutics without a scientific symptomatology. It was not until it was realized that disturbances of function are many times more important than disturbances of structure that therapeutics could develop upon a scientific basis, and the great development of the next few years in medical science will be along the line of therapeutics, and accurate therapeutics, based upon a scientific knowledge of disturbances of function. So old regenerated Detroit welcomes a regenerated therapeutic science.

But Detroit needs an apology as well as praise. We have the distinction of being a great city, but we also have the unique distinction of being the only city of its size in the world, with the possible exception of some of the great Oriental cities, like Pekin, and I am not certain about that, that has no great institution of learning. Detroit in its development has been deprived of the enlightening and uplifting influence of a great university, and that is its great misfortune. We have grown up without having in the midst of us a body of men devoted to learning and to culture, and so we have developed perhaps a little too much along commercial lines. We have learned how to produce wealth, but we are so new that we do not know how to spend it. We need to learn that. That comes with a prolonged possession of wealth. We will learn some day, and will perhaps be an intellectually as well as commercially regenerated Detroit.

We are embarrassed just at the present time because we have so much of entertainment on our hands. We should love to welcome you in a more abundant way, but unfortunately we have this great American Medical Association meeting so soon; we have the American Academy of Medicine, the American Proctological Society; we have the alumni meeting of the Detroit College of Medicine and the graduating exercises, and all these burden us, and we are like a hostess with an overburdened house at a week end. Notwithstanding all this, we give you the liberty of the city, and permit you to enjoy yourselves in the best and most profitable way that you can.

RESPONSE TO THE ADDRESS OF WELCOME

To the American Therapeutic Society, June 9, 1916,

By Thomas E. Satterthwaite, M. D., Sc. D., LL. D.,
New York.

Gentlemen: We are today surrounded by an atmosphere of progress, in a part of our country where pioneer work of various kinds is being done; much of it, I feel, on enduring lines. In fact, I believe we may look to the Middle West confidently

for the most intelligent opinions on the great questions of the day.

Our sessions have heretofore been in New York and Montreal, in Boston and San Francisco, and intermediate points, but we have now invaded a section of our country which in some respects carries the banner in our march of progress. Certainly, Michigan, Illinois, Wisconsin, Missouri, and Minnesota are in the van as to medical legislation and institutions, for Ann Arbor and Detroit, Chicago, Minneapolis, and St. Paul, and Rochester, Minnesota, can now testify to medical achievements of the first rank in the history of American medicine. Was not the Northwestern University of Chicago the first in the Middle West to require preliminary education before entering on medical studies? And did it not, in 1859, institute a longer curriculum with graded courses? And in 1890 did not the University of Michigan introduce a compulsory four years' course, with a graded curriculum, making hospital experience an integral part of the medical course? And now, for more than ten years, Chicago, Ann Arbor, and Minneapolis have had four year graded courses; and they were, I believe, the first institutions of the country to introduce them. In fact, they were in existence, if I am correctly informed, as early as 1903.

Besides, it is here in your Middle West that you have succeeded in convincing the general public that the use of public hospitals is *primarily* for undergraduate medical instruction. We in the East have not been so successful in combining college lectures with hospital experience. It is true we had this in mind in starting the New York Post-Graduate Medical School and Hospital in 1882, as the name indicates, but we did not get our hospital until 1885. The New York Polyclinic followed, with an associated hospital. Our difficulty in the Post-Graduate School was trivial, because the medical men who founded it always owned it, and lay influences never had any part in directing its policies. As it enlarges—and it is always growing larger—the school and hospital will, it is hoped, always be under one roof. But these are graduate, not undergraduate institutions.

Going further to the west, I feel proud that one of my early students in the Post-Graduate School has been the founder of a medical institution which also shows what concentration of intelligent effort can accomplish. It may be said with truth that at Rochester some results obtained have surpassed those of any other locality in the world.

By looking over our membership roster, it will be seen that it embraces men in the more important specialties. At one time or other we have admitted specialists in every department of medicine and surgery. Their proportionate representation has varied from year to year. So far as the American Medical Association is concerned, we classify them somewhat differently, but actually, even with our small numbers, we recognize more specialties. For example, the stated sections of the American Medical Association are as follows:

1. General medicine.
2. Surgery.
3. Obstetrics and gynecology.
4. Ophthalmology.
5. Otology, laryngology, and rhinology.
6. Pediatrics.
7. Pharmacology and therapeutics.
8. Pathology.
9. Physiology.
10. Nervous and mental diseases.
11. Dermatology.
12. Preventive medicine and public health.
13. Genitourinary diseases.
14. Orthopedic surgery.

We have recognized all these in the American Therapeutic Society, and in addition: 15, Anatomy, 16, Bacteriology, 17, Immunology, 18, Medical jurisprudence, 19, Materia medica, and, 20, Climatology.

Most of our members are or have been teachers. Two years ago, I found that we had about fifty professors among our members. In the latest roster, of 1915-16, I have found by inquiry that of the hundred members sixty were or had been professors, twelve associate professors, and ten teachers, making a total of eighty-two per cent. These figures indicate fairly well the quality of our membership. The tables of 1916-17 will show a still further increase in the quality of the men.

Most of us are aware, I am sure, that we are being entertained by the medical profession of one of our oldest cities, on a river that not only transports more tonnage than any other river in the world, but has on it a beautiful island park, Belle Isle, one of the thirty of the City Beautiful. With a population less than a million, you of Detroit have made of late such giant strides in your industrial life, and have accumulated so much material wealth, that your future prosperity seems assured. Your Detroit College of Medicine and Surgery, founded in 1913, and therefore only three years old, is a proof of your pioneer spirit, with its preliminary entrance requirements, graded curriculum, five year course, clinical opportunities, and laboratory facilities. It is not to be wondered at that the proportion of medical students to the population is greater than that of any other city in the United States. Nor am I aware of any other place where hospitals and medical institutions are so open for clinical instruction. In this respect and in your laboratory facilities you have set an example for our more conservative laymen in the East.

Again, if I am correctly informed on these matters, your eleven hospitals, asylums, and homes offer 1,300 beds for medical instruction. If you are imbued with the university idea, as I have no doubt you are, you are already working for a closer affiliation of your medical bodies.

Apart from this, some of you will, I know, join with me also in thinking that you have with you one of those men whose name is to be remembered in history, as far sighted and great enough to throw his energies and soul into the diabolical caldron of hate and fury that has characterized the terrible European conflict. Even if his efforts have not been immediately successful, they have had a healthful influence.

John Brown failed in his mission, but his soul went marching on. Were Ford's efforts a failure? I believe not. He tried to secure peace at a time when his method was the only one that offered any hope of ultimate success. Fortunately I, and you who are my associates in the army of the United States, have prepared ourselves for any results of the jealousies of ambitious men, and of our own in-

ternal dissensions, if any such should arise. God grant we may not be called upon. Our preparedness spells peace, and we have been fellow laborers with Mr. Ford though our methods have been different.

As I have intimated, the field before us at this session is a broad one, for therapeutics necessarily includes all its branches, special as well as general, experimental and applied, pharmacal and nonpharmacal. It is true that apart from operative methods, and the application of mechanical contrivances, there has been a steady increase in our nonpharmacal remedies, of which hydrotherapy, massage, pneumotherapy, psychotherapy, phototherapy, electricity in many forms, and the application of cold and heat are good examples. We are forced to admit their powers, for each one of them has established a claim to be recognized as an important aid to our work. Yet after all, the administration of the organic and inorganic materia medica of our pharmacopœia plays such an important part in the management of disease, that pharmacology (taking it in the broad sense inclusive of materia medica) cannot be dissociated from therapeutics. If the aim of the science of medicine is the prevention, cure, or amelioration of disease, then therapeutics is its most important branch. The therapeutic nihilist may exist, and talk profoundly of the *vis medicatrix naturæ*, but the medical colleges of the United States will, notwithstanding, continue to believe that therapeutics is worthy of a chair; encyclopedias of medicine will recognize it as a distinct department, international medical congresses will dignify it with capital letters, and the section devoted to it will not be surpassed in practical results by any other.

In early times the application of remedies was empirical. Accident led to the discovery of mineral springs, and the virtues of Peruvian bark. It will always be helpful, but at the present time, new remedies are almost wholly the results of tests on the lower animals, corroborated by clinical experience. When Vesalius by his physical researches instituted a campaign of personal investigation that eventually led to the discovery of the circulation of the blood, and laid the foundation of scientific medicine, he opened the way for the therapeutics of today.

It is by research work in the fields of medicine and surgery that this progress has been made. Accident has played a comparatively small part in this work. It has for the most part merely given us clues by which to work out our problems. The late Dr. Carlos Finlay, of Havana, suggested, in 1881, that yellow fever might be communicated by the mosquito, but even before his time the Indians of Central America knew that by netting the entrance to their tents fevers were kept out. It remained for the United States Yellow Fever Commission to discover, some years later, that it was a single variety of mosquito, Culex fasciatus, that conveys the poison, and that protection from this mosquito gives immunity from the disease. We all know now that this discovery has reduced the incidence of yellow fever to a minimum; in fact, the fever has been almost eradicated.

In the case of the Loeffler bacillus of diphtheria and the plasmodium of malarial fever, the discoveries were due to intelligent, patient, laborious research. If we find that beriberi and pellagra are caused by the present milling processes, these discoveries also will have been the result of long and patient labor. What may be accomplished by such researches is shown by our successful handling of the hookworm disease, and by antityphoid, anticholera, and antiparatyphoid inoculations.

Only a confirmed antivivisectionist will say that therapeutics is not advancing. We know it is going forward by leaps and bounds; but many do not realize in figures how important the discoveries of late years have been, so far as the saving of life is concerned. We believe that in diphtheria antitoxin a remedial agent was introduced that has saved thousands of lives, and we know that it has practically done away with intubation in laryngeal diphtheria. But in many other respects we do not appreciate the full force of our advances; often, however, these matters may be reduced to figures. For example, in Rome the mortality charts show that, in 1887, malaria ranked in mortality with tuberculosis and other great infections, killing in Italy in that year over 30,000 persons (Osler). In 1906, less than 5,000 died of the disease, and in 1907 a few over 4,000. By protecting dwelling houses against mosquitoes, and by legislation for the gratuitous distribution of quinine, the great destroyer of the plasmodium, the fatality from malaria was reduced to the last named figures.

The American Therapeutic Society is not an organization devoted to materia medica; it is a society of specialists, embracing, according to the intention of its founders, every department of therapeutics in medicine and surgery. It has been no easy matter to gather these specialists together so as to get new light on therapeutic weapons. But our meetings have been fruitful in results. At one of them a discussion on the borderline diseases took up their surgical versus their medical side. From one of the surgeons present came the statement that the profession had learned much from medical men about the treatment of appendicitis, which only a short time previously had been declared by one of the best known writers on internal medicine to have no medical side. One distinguished member, now our president, was the first, I believe, to come forward and say that in certain forms of appendicular diseases surgical treatment is not called for. So the world moves; and so much for the scope and aims of the work of this society. It brings together a coterie of experts and general practitioners, able to discuss intelligently the prophylaxis and treatment of every affection in the whole range of our art and science, making possible a degree of progress impossible in special sections.

One of the dangers of the day is overspecialization. The modern tendency is to work in an ever narrowing field, and to lose our appreciation of what is being done about us. It is imperative, therefore, that we should at times come together, listen to one another's views, and compare results. In this way we lift the topic under discussion from the narrow rut in which it may have been placed

by specialization, and illuminate it by the white light of truth that comes only from a combination of all the different colored rays.

It was no small thing to start a national society with therapeutics as its object, especially as the founders would certainly and naturally be credited with commercial aspirations. But the principles upon which this society was organized, as stated in its constitution and by laws, soon showed the profession that commercialism could not exist in the organization, and that a member indulging in such practices would, *ipso facto,* cease to belong to it. We are quite ready to recognize the energy and intelligence shown by our great pharmaceutical houses, and realize fully that they employ the best medical talent obtainable, are certainly adding to the sum of human knowledge, and aid us in unnumbered ways in our combat with disease. But, though they enlist our interest and invite our admiration, we nevertheless draw a sharp line between the practice of medicine and commercialism. Established in these principles, this society has given expression to every phase of scientific therapeusis consistent with the ethical practice of experimental and applied medicine and surgery in all their branches.

Contemporary Comment

The Frequency of Hereditary Syphilis.—The frequency of hereditary syphilis, remarks *Pediatrics* for November, 1916, is a matter concerning which there has been a great deal of discussion but no general agreement. It is obvious that to trace accurately the frequency of any hereditary disease is by no means an easy task, and the reliability of such figures is dependent on many factors. Dr. Frank Spooner Churchill and Dr. Richard S. Austin, who wrote on the subject in the *American Journal of Diseases of Children* for October, made an inquiry as to the incidence of hereditary syphilis, drawing their final conclusions from an analysis of the literature, and an intensive study on their own part of 695 patients at the Children's Memorial Hospital, Chicago.

Their conclusions are as follows: Statistics as to the frequency of any given disease must be based on large numbers of patients, carefully and accurately studied as to diagnosis. The diagnosis must be made after judicious weighing of all the evidence, both clinical and laboratory. Study of the literature on the incidence of hereditary syphilis shows a wide range of results, it being variously estimated at from two to fourteen per cent. in Europe and America. Intensive study of a group of 695 patients in the Children's Memorial Hospital, during the winter of 1915-1916, the study embracing both clinical and laboratory methods of investigation, shows an incidence of 3.3 per cent. of hereditary syphilis. The amount of hereditary syphilis among the hospital infants and children in four large cities of the United States, New York, St. Louis, San Francisco, and Chicago, appears to range from two to six per cent.

War Hurts Attendance at the University of Toronto.—Figures recorded to date in the registrar's office at the University of Toronto, remarks the *Dominion Medical Monthly* for December, 1916, show the ravaging effects of war on the enrollment lists of all the faculties of the university. The registration of students in Arts, Applied Science, Medicine, and Forestry is practically complete, and the records show that in some cases the number of students now enrolled is less than half that of 1913-14. . . . Undergraduates and graduates of the University of Toronto serving with the colors now number 3,020. Over 140 University of Toronto men have given their lives for the British Empire.

The Book Agent Impostor.—Several months ago, remarks *Northwest Medicine* for November, 1916, we published a warning against a swindling book agent, who was reported to be working physicians of the far west. During the past month we have received letters from two eastern publishing houses, again sounding warning against this man who styles himself B. T. Little, and who is reported to have recently worked the physicians of Washington and Oregon. He states that he is a representative of one or more publishing houses in the east and solicits orders for medical books and subscriptions to various medical journals, beside collecting on accounts due various publishers. He tries to put over the old swindle of working his way through college, and says he represents a students' benefit association. It seems as if any physician in his right mind would have sufficient regard for his own finances not to pass out money for medical literature without assuring himself of the standing of the man he is dealing with, but it seems that doctors in both Oregon and Washington have reported themselves as victims of this impostor. A word to the wise should be sufficient.

Notification of Pregnancy.—The compulsory notification of pregnancy to the health authorities of every community is the plan suggested by a speaker at the recent annual meeting at Milwaukee of the American Association for the Study and Prevention of Infant Mortality, observes the *Lancet-Clinic* for November 11, 1916. The notifications are to be treated confidentially, and would be designed to furnish the necessary information to the health authorities, "who should be required to determine that proper prenatal and safe obstetric care are assured to each prospective mother," to quote the speaker, Dr. Arthur B. Emmons, of Boston. It savors much of coercive legislation, and recalls the methods in vogue in the paternalistic governments of Europe, which we are wont to decry; yet when one considers that forty per cent. of the infant mortality in this country is due to inadequate care at the time of parturition, stringent measures would seem in place. The scheme would bring to thousands of prospective mothers inoculated with syphilis or infected with the gonococcus proper medical attention. Perhaps the advantages of such a notification might be made so attractive that women would voluntarily acquaint the health authorities with their state. But whether voluntary or compulsory, the adoption of the plan would reduce infant and maternal mortality.

THE NEGLECT OF HYPNOSIS AS A THERAPEUTIC AGENT.

The days when hypnosis was first applied in a practical manner in the treatment of disease were days of argumentation as to the nature of this remedial method. Modern hypnosis had its origin in mesmerism; and because mesmerism was associated in most people's minds with mystery, the same attitude was in the beginning assumed toward hypnosis. In fact, the struggle which ensued right within the field of medicine proper among some of the foremost neurologists in France as to the exact nature and method of action of hypnosis, led to decided uncertainty and skepticism on the part not only of the lay people but of physicians themselves. even the neurologists, psychopathologists, and psychiatrists in no small number. Under such circumstances, with such theories as that of "magnetic fluid" floating in the air, and being disseminated and whispered far and wide, it is not at all astonishing that a general attitude of distrust was impressed upon the medical profession. Furthermore, the employment of advertising methods and quackery in the exploitation of the apparent mysteries of hypnosis for commercial purposes, strengthened this attitude. The profession looked with suspicion upon any one who employed hypnosis as a therapeutic agent.

In spite of this, however, in France, England, and elsewhere, and not least in the United States, certain workers in the field of psychopathology devoted themselves to the scientific study of hypnosis, so that it has been taken out of the realm of mystery, quackery, metaphysics, and the unknown, and its nature and method of producing results have been clearly and scientifically established.

Hypnosis as a therapeutic agent has come to stay. In fact hypnosis is employed by the foremost psychopathologists, and so firmly has its therapeutic value become established, and so well recognized is it by all who have had the good sense to employ the method in suitable cases, that it is truly astonishing to find how much ignorance on this matter exists, and how little used as an instrument of definite therapeutic value we find it among the rank and file. Boris Sidis, in his *Symptomatology, Psychognosis. and Diagnosis of Psychopathic Affections,* has expressed the idea we have in mind so well, that we cannot refrain from quoting him at length:

> From a practical therapeutic standpoint hypnosis is of the utmost importance. Whenever it is possible the hypnotic state should be used for the alleviation of nervous and mental suffering. Not to avail oneself of hypnosis in the treatment of mental troubles and claim the omnipotence of some other method as a panacea for mental affections is to show undue enthusiasm not justified by experience. Many psychopathic cases have been treated by me and cured permanently by means of hypnosis alone. Some of the cases were of severe character, and the employment of other states and methods would have required months, if not years of treatment with possibly no chance of recovery, on account of the dragging character of the treatment. Treated by hypnosis the patients became permanently well after a few treatments. . . . This can hardly be affirmed of any method no matter how enthusiastic one may be about it. Whenever, therefore, it is possible to obtain a deep hypnosis the latter should by all means be used. Hypnosis is a powerful instrument in the armamentarium of psychotherapy, and the medical man who wishes to get results should cultivate its use.

When a man of the scientific probity and standing of Sidis comes forward with such an unequivocal statement, it means something. But Sidis does not stand alone in this, since all broadminded psychopathologists here and abroad who have employed the method have come to the same conclusion.

Every medical man of average ability who will devote the time and effort to master hypnosis can apply it practically in his work. It behooves the average practitioner to take notice and to act accordingly.

OUR DAILY BREAD.

The importance of nutrition and the need for better regulation of our food supplies are urgent questions of the day. In the effort to improve these conditions we should not neglect the physiological aspect of the subject. The science of dietetics is rap-

idly changing our views on nutrition, and presenting helpful rules for dietary guidance. We are no longer wholly dependent upon our culinary art and the instinctive cravings of appetite. By applying the principles of dietetics, it is now possible to correct common errors in diet, to prevent waste, and to promote judicious economy. In this field of endeavor a great deal can be accomplished by giving simple advice regarding habits of eating and overeating. By these means many prodigals would be saved, and taught to invoke the three Graces of the table: Variety, simplicity, and moderation. We should remember the old Roman adage to take only so much of food and drink as to refresh and not oppress the powers of the body.

In discussing this subject before the Second Pan-American Scientific Congress, Professor Lafayette B. Mendel (*Changes in the Food Supply and Their Relation to Nutrition*) called attention to our modern conditions and referred to some remarks of Professor Rubner which are so pertinent that we quote them herewith: "The nutrition of the masses is to us a problem which may be approached from many sides. It is necessary that not only the hygienists, in the narrower sense, take up the struggle for betterment, but that also the great army of men who are truly humane in their hearts, shall take their places beside us. The battle which we have to carry on is not only against unavoidable and natural difficulties; we must not forget that human society includes many elements, unwilling to make the least concession to a humanitarian movement, persons whose prosperity is selfishly held superior to the welfare of their neighbors, and who will oppose such a movement with all the means at their command. Let us hope that our opponents will, at the last, rejoice with us in a triumph of the Humane Idea."

DEFECTIVE CHILDREN.

In civilized countries no problem is harder to solve than that of defective children. In industrial countries, in lands in which the population is massed together and living under unhygienic conditions, degeneracy advances and feeble mindedness is common. Of all the causes of feeble mindedness none is more frequent than syphilis, and feeble minded parents will beget children with similar mental defects. How can we deal with persons whose mental capacity is subnormal, or abnormal, so that they will be happy and even useful and, at the same time, not be a menace to the community? If they are allowed to be at large and to procreate and bear children, their mental defects are likely to be transmitted on a large scale. The criminal class is almost wholly recruited from the ranks of these defectives, as they are practically all potential criminals. Sixty per cent. of prostitutes are defectives; they constitute a social danger of the gravest character. Defectives supply the great majority of murderers, thieves, and social outcasts of every variety. They are responsible mainly for the spread of venereal infections which are the real origin of many of our physical and mental diseases. By permitting freedom to mental defectives a vicious circle is established which may widen until a whole race is compromised. Defective children cannot be properly educated along with normal children; they deter the children with whom they are associated, and tend to contaminate them. There is little or no difference of opinion among those who have studied the matter that steps should be taken for their own salvation and to safeguard the public at large. The entire question, however, simply bristles with difficulties. The most sensible plan is segregation, and undoubtedly the best way to segregate them is on farm colonies, where they are well supervised, educated to the extent their limited intelligence will allow, learn the trades best adapted to their deficient brain power, and lead healthy lives. This plan has met with success whenever it has been carried out; the obstacles, however, in the way of its universal adoption are many. Cost is frequently the stumbling block, State and city authorities being often so penny wise and pound foolish as not to appreciate the fact that as a menace to health and society the defective, left to his or her own devices, will soon be a greater expense to the community than the outlay of the few dollars required to put into operation the necessary preventive measures. The cost of crime alone is colossal. The cost in ill health due to these victims of heredity is even greater, and the harm they do to the cause of morality cannot be estimated in money. The cost is but one of the reasons why defective children are not dealt with in an effective manner. Before a mentally deficient child can be committed to institutional care, farm colony or what not, the case must be diagnosed by an expert and the permission of parents or guardians must be obtained. The psychiatrist cannot go to the defective child and although psychiatric clinics are established now in the hospitals of most big cities, it is by no means an easy matter to induce the parents of mentally deficient children to take them to such clinics for examination. Moreover, even when children are known to be below par, the parents are often averse to allowing them to go to an institution, especially when they are not very obviously defective. There is a certain amount of stigma attached to institutional life and, moreover, the defective offspring at home is often a source of revenue.

The best means of impressing upon the general public the menace of the defective is by education with regard to the whole matter. When the people at large comprehend the nature of the danger, they will insist that measures be taken at least to minimize it, and cost will not be allowed to stand in the way.

INJECTION OF NONSPECIFIC PROTEINS.

The response of a sensitized animal to the parenteral injection of the specific protein is a matter of common knowledge, although the precise mechanism of the response is still a subject of debate. Among other theories we may recall that of Vaughan, which postulates the liberation of protein split products, a fraction of which is toxic. It is also well known that the parenteral injection of a nonspecific protein in an unsensitized animal is followed by certain more or less constant phenomena, among them the tendency for the body temperature to rise and for the leucocytes in the blood to increase in number. Very recent observations made by R. Müller seem to show that in localized inflammatory processes the injection of a nonspecific protein is also followed by a local hyperemia and an increased transudation into the inflamed tissues. Good use was made of this reaction in the treatment of gonorrheal complications, buboes, staphylococcal, and other local inflammations.

Following this lead L. Müller and C. Thanner (*Medizinische Klinik,* October 22, 1916) tried this form of therapeutics in certain ocular affections, largely because many of these conditions have long been treated with agents which provoke local hyperemia. Their results were so favorable as to justify a brief summary.

Four cases of parenchymatous keratitis of hereditary luetic origin were thus treated, with immediate relief of the photophobia and pain, and marked shortening and reduction in the severity of the course of the affection. All of the cases had previously been treated with antiluetic remedies without effect. Eleven cases of iritis were also injected with protein with the most favorable results. In these the photophobia and pain disappeared on an average in twenty-four hours after the first injection. One case with an old history of gonorrhea was promptly relieved. Cloudy cornea and choroiditis also responded well, but the cloudiness was not totally removed in all of the cases. Finally, conjunctivitis was favorably influenced by the treatment, the edema being promptly cleared up.

The protein employed was that of whole milk, and for the purposes of treatment the milk was boiled for four minutes just before injection. The dose, from five to seven mils, was injected deep into the gluteal muscles, care being taken that no vein had been entered. The injections proved somewhat painful for a short time, but no ill effects were observed in any case.

IS PELLAGRA CONTAGIOUS?

The prominence with which pellagra has come before the profession in recent years has caused all aspects of the disease to be investigated; thus we are gradually amplifying our knowledge of it. Many beliefs and theories, at first held by occasional observers, have been rejected in the light of more complete data. Others still hold sway, although as more and more investigations are being made, the ground tends to crumble from beneath them. The impression, for example, seems to be fairly widespread, although countenanced by practically no direct proof, that pellagra is contagious. It is true that it bears certain superficial analogies to many infectious diseases which are also contagious. The only direct evidence of which we are aware which would seem to argue in favor of the contagiousness of the disease is the report of the successful inoculation of a monkey by Harris in 1913, with filtrate from pellagrous lesions. Later on, however, this same observer, in further experiments, got different results, as did Lavinder and Francis. The question then was still undecided until the recent work of Goldberger.

Goldberger determined to test the matter by actually subjecting human subjects to exposure. A number of persons volunteered, and fifteen men and one woman were selected. Thirteen of this number were physicians. The materials used were blood, nasopharyngeal secretions, epidermal scales from pellagrous skin lesions, urine, and feces. The blood was administered by intramuscular or subcutaneous injections, the secretions by application to the mucosa of the nose and nasopharynx, and the excreta were given by mouth. The pellagrous material was obtained from seventeen cases, varying in severity, and including three fatal cases. As insanitary methods of sewage disposals have often been alleged to be responsible for the transmission of pellagra, special attention was given to the excreta; the infectiousness of both urine and feces was tested six times. The blood was tested twice, the nasopharyngeal secretions twice, and the scales from lesions three times. No change was made in the subjects' diet or in their manner of living.

The experiment was carried on during a period of from five to seven months, and in none of the subjects did any symptoms develop to justify a diagnosis of pellagra. Goldberger (The Transmis-

sion of Pellagra, *Public Health Reports*, November 17, 1916) therefore concludes that pellagra is not a communicable disease, but one of dietary origin, brought about by faulty, probably deficient diet. The conclusion bears out the one at which he and Wheeler arrived in 1915, when a group of convicts received a diet deficient in certain elements, with the result that in a number of them the disease developed.

THE CLOTHES OF CANCER PATIENTS.

Ettie Sayer, of London, writes to the *Lancet* for December 2, 1916, on the possibility of the transmission of cancer along with discarded clothing. The letter speaks of two patients with inoperable cancer of the cervicothoracic region who have inherited and worn the clothes of relatives who died from similar growths in similar local positions, the one six years ago and the other eight. In the latter case the patient exhibits a striking replica of his late brother's growth. The absence of any weighty opinion in support of some definite interim procedure obstructs the carrying out of hygienic measures in dealing with cancer that are employed in conditions which are in many other respects the same. People are not willing to sacrifice the property of relatives who have died from a disease which they have been assured is solely due to "eating meat," or to "chronic irritation," or to a "birth cell gone wrong."

There is no bacteriological proof that "cancer" is actually associated with a microbe. But clinically one gets abundant evidence of a something which superimposes itself upon tissues that have become devitalized through having had to carry on a lengthy state of warfare with certain chronic bacteria, playing the role of forerunner to more virulent microbes. Not only has a bacterial preparing of the way (by some such herald as that which is responsible for fibrositis) been a feature in every case that has occurred within the correspondent's experience during recent years, but also every local alleviation that he has managed to obtain has been due to the help of a remedy possessing bactericidal properties. Sayer states that he has never seen a cancer case without sepsis somewhere.

News Items

Change of Address.—Dr. Alfred C. Reed, to 350 Post Street, San Francisco, Cal.

Yellow Fever.—Quarantine measures on account of yellow fever were instituted on November 21st by the Cuban quarantine service against arrivals from the Island of Martinique.

Philadelphia Medical Examiners' Association.—Dr. Lawrence Eisenberg was elected president of this society at its recent annual meeting; Dr. Howard M. Kuehner was elected vice-president and treasurer, and Dr. M. C. Neufeld, of Chester, secretary.

New Officers of the Eastern Medical Society.—At the annual meeting of the Eastern Medical Society of the City of New York, held on Friday evening, December 8th, Dr. I. Seth Hirsch was elected president and other officers were elected as follows: Dr. H. E. Isaacs, first vice-president; Dr. G. G. Fishlowitz, second vice-president; Dr. Joseph F. Saphir, recording secretary; Dr. A. A. Hilkowich, treasurer.

Leprosy in Newark, N. J.—It is reported that Newark has a case of leprosy in the isolation ward of the City Hospital. The patient is a Syrian rug peddler who arrived in Newark a week ago from Springfield, Mass.

Smallpox in Connecticut.—The health officer of Waterbury, Conn., reported by telegraph on December 4th to the United States Public Health Service that there were present in that city twenty-one cases of smallpox of a mild type.

Philadelphia County Medical Society.—The following officers were elected at the recent annual meeting of the North Branch of this society: Dr. Maximilian D. Bloomfield, chairman; Dr. Carle Lee Feldt, vice-chairman; Dr. M. P. Warmuth, vice-president of the County Society.

Poisonous and Disease Carrying Insects of Philadelphia.—At a meeting of the Philadelphia County Medical Society, held on Wednesday evening, December 13th, Mr. Herman Hornig, city entomologist, delivered an address on Poisonous and Disease Carrying Insects in and Around Philadelphia. The lecture, which was illustrated with over one hundred lantern slides, gave details regarding the many types of flies, malarial bearing mosquitoes breeding in the vicinity of Philadelphia, caterpillars, etc. The program was arranged by the Committee on Insect and Animal Transmitters of Disease.

Personal.—Dr. Henry Dwight Chapin, of New York, delivered an address on the Relationship of Pediatrics to General Medicine, at the twentieth anniversary meeting of the Philadelphia Pediatric Society, held Tuesday evening, December 12th.

Dr. Theodore LeBoutillier, of Philadelphia, has been appointed pediatrist to the Philadelphia General Hospital.

Professor Lawrence G. Henderson, of Harvard University, delivered the annual Samuel D. Gross Lecture of the Pathological Society of Philadelphia, Thursday evening, November 9th, his subject being Acidosis.

Dr. L. V. Heilbrun has been instructor in microscopic anatomy at the College of Medicine of the University of Illinois.

New York Geriatric Society.—The next meeting of this society will be held on Wednesday, December 20th, at the St. Agnes Branch of the New York Public Library, 444 Amsterdam Avenue, New York. The subject for discussion will be Surgery in the Aged. Papers will be read by Dr. Robert T. Morris, Dr. Parker Syms, Dr. Walter M. Brickner, Dr. Edward Wallace Lee, and Dr. F. C. Yeomans. Among those who will participate in the discussion are Dr. Howard Lilienthal, Dr. Gordon K. Dickinson, Dr. A. Sturmdorf, and others. Physicians are cordially invited to attend. Dr. I. L. Nascher is secretary of the society.

Meetings of Medical Societies to Be Held in Philadelphia during the Coming Week.—Monday, December 18th, Clinical Association, Medical Society of the Woman's Hospital; Tuesday, December 19th, West Branch of the County Medical Society, Academy of Stomatology; Wednesday, December 20th, Section in Otology and Laryngology of the College of Physicians; Thursday, December 21st, Section in Ophthalmology of the College of Physicians, Southeast and Northeast Branches of the County Medical Society; Friday, December 22nd, South Branch of the County Medical Society, Northern Medical Association.

Medical Association of the Greater City of New York.—A stated meeting of this society will be held in Du Bois Hall, New York Academy of Medicine, Monday evening, December 18th, at 8:30 o'clock. Dr. William P. Emerson, professor of pediatrics at Tufts Medical School and physician in charge of the nutrition clinics of the Massachusetts General Hospital and Berkeley Infirmary, will read a paper on the Faulty Food Habits of Delicate Children and will show a food exhibit demonstrating a simple method of checking up diet, which will apply to underweight and overweight in older patients; also to low protein, carbohydrate or fat as desired. The subject will be discussed by Dr. H. R. M. Landis, director of the Phipps Institute, Philadelphia, Dr. Graham Lusk, Dr. Charles Gilmore Kerley, Dr. L. E. La Fetra, Dr. Charles F. Bolduan, and others.

Fatalities from Street Accidents.—According to the report of the police commissioner, 65 persons lost their lives in New York during the month of November, 1916, as the result of street accidents. Of these 23 were killed by motor trucks, 19 by passenger automobiles, 7 by horse drawn vehicles, 7 by electric cars, and the rest by motor cycles, falls, and collisions. Thirty-two of the victims were children. The report of the National Highways Protective Association says that during the eleven months of 1916 in New York city 363 deaths were caused by automobiles, 74 by trolleys, and 71 by wagons, compared with 312 by automobiles, 69 by wagons, and 69 by trolleys in 1915.

The Sherley Amendment.—The Circuit Court of Appeals for the Third Judicial Circuit of the United States has upheld to a decree of forfeiture of a shipment of "patent medicine" on the ground that the labels contained false and fraudulent statements regarding the curative effect of the medicine. The suit was brought under the Sherley amendment to the United States pure food and drugs law. Judge Buffington, in the opinion, said that the purpose of the Sherley amendment was to "punish false and fraudulent statements regarding the curative or therapeutic effect" of drugs shipped in interstate commerce. The opinion is published in the December 8th issue of *Public Health Reports.*

The Yorkville Medical Society of the City of New York.—A stated meeting of this society will be held at Aschenbroedel Club, 144 East Eighty-sixth Street, Monday evening, December 18th. The principal business to be transacted at the executive session will be the election of officers and the reports of standing committees. The scientific program will consist of a symposium on diseases of the nose and throat. Papers will be read as follows: Acute Infections of the Nose and Throat, by Dr. Louis H. Schwartz; Chronic Infections of the Nose and Throat, by Dr. Max Marschark; The Nose and Throat as Portals of Entry in Contagious Diseases, by Dr. Louis Foscher; Complications and Sequelæ, by Dr. J. Davidson; Focal Infections from the Nose and Throat, by Dr. E. D. Friedman. The discussion will be opened by Dr. Wolff Freudenthal and Dr. Sidney Yankauer.

American Laryngological, Rhinological, and Otological Society.—The following officers were elected at the annual meeting of this society, to serve for the year ending June 2, 1917: Dr. Thomas J. Harris, of New York, president; Dr. John F. Culp, of Harrisburg, Pa., first vice-president and chairman of the Eastern Section; Dr. John E. Brown, of Columbus, Ohio, second vice-president and chairman of the Middle Section; Dr. James A. Patterson, of Colorado Springs, Colo., third vice-president and chairman of the Western Section; Dr. Richmond McKinney, of Memphis, third vice-president and chairman of the Southern Section; Dr. Ewing W. Day, of Pittsburgh, treasurer; Dr. William H. Haskin, of New York, secretary; Dr. H. Holbrook Curtis, of New York, librarian; Dr. George L. Richards, of Fall River, Mass., chairman of the publication committee. The next annual meeting of the society will be held at the Clifton Hotel, Niagara Falls, Ontario, June 1 and 2, 1917.

Dysenteric Epidemic in Alabama.—The health officer of Talledega County, Alabama, reports to the United States Public Health Service that during previous years typhoid fever and cases of diarrhea have been rather common in Talladega, particularly among new comers. Following a change in the water supply from a polluted spring to an artesian well, the typhoid and diarrhea were greatly reduced in prevalence. About October 20, 1916, the present outbreak began with about fifty new cases each day. These cases were characterized by an acute onset, a griping pain in the abdomen, diarrhea, and some nausea. Many had fever and were prostrated. The diarrhea persisted for from a week to six weeks and frequently reappeared after a few days' intermission. No deaths appear to have been due directly to the condition. On November 30th at least one fourth of the population is believed to have been affected. An officer of the Public Health Service has been detailed to make an investigation.

The Mississippi Valley Medical Society to Have an Official Organ.—Beginning with the January, 1917, issue, the Louisville Monthly Journal of Medicine and Surgery will become the official organ of the Mississippi Valley Medical Association, appearing with that issue in a new form and under the name of the *Mississippi Valley Medical Journal.* Dr. Henry Enos Tuley, secretary of the association, will continue as editor; Dr. H. H. Grant as business editor, and a special editorial committee, composed of the following, will assist in the editorial policy of the journal: Dr. William N. Wishard, of Indianapolis; Dr. Arthur R. Elliott, of Chicago; Dr. Willard J. Stone, of Toledo, Ohio, and Dr. Louis Frank, of Louisville. It is announced that a special epitome department will be established, giving each month a review of some special borderline topic.

Deputy Collector, Inspector, and Agent, Antinarcotic Act (Male).—The United States Civil Service Commission announces an open competitive examination for deputy collector, inspector, and agent, under the antinarcotic act, for men only, on January 3, 1917. From the register of eligible persons resulting from this examination certification will be made to fill about seventy-five vacancies in this position in the Internal Revenue Service, Treasury Department, at $1,600 a year, with actual traveling expenses and subsistence when away from post of duty on official business. There is opportunity for promotion to salaries of $5 and $6 per diem, with allowance of $3 per diem for subsistence and actual traveling expenses. The duties of this position will include the supervision and inspection of the sale of opium and coca leaves and their derivatives under the provision of the Harrison Antinarcotic Law approved December 17, 1914, and the detection of violations thereof. Graduation in pharmacy or medicine from a recognized institution, or the possession of a State license to practise pharmacy, is a prerequisite for consideration for this position. For full information regarding the examination address the United States Civil Service Commission, Washington, D. C.

Civil Service Examination for Psychiatrist.—The Municipal Civil Service Commission announces that applications will be received up to 4 o'clock in the afternoon of Friday, December 29th, for an examination, open to both men and women, for the position of physician for the examination of mentally defective children. From the list of eligible persons obtained from this examination certification will be made by the Department of Charities to fill a vacancy in the position of senior physician, at $2,520 per annum with full maintenance, and three positions of resident physicians at $1,500 per annum with full maintenance at Randall's Island Hospital and Schools for Children.

The duties of the position of senior physician in the Department of Charities are to assist the director of Randall's Island in the administration of the institutions and to directly supervise the clinic and the assisting physicians. The duties of the three resident physicians will be to assist in the care and treatment of mentally defective children.

The opportunities for exceptional experience in this specialty for the successful candidates are very great in view of the extensive field that New York presents for close association with so many prominent consulting physicians. The institutions at Randall's Island care for approximately 2,100 patients with an admission of 1,000 cases annually, including borderline psychopathic and delinquent cases. Owing to this active service, which is the largest in the United States, and the well equipped pathological laboratory, it is said that the opportunities for clinical, psychological, and pathological work with mental defectives and epileptics are unexcelled. Candidates for the position must have a license to practise medicine in the State of New York or must procure one prior to certification. They must also have had experience in the diagnosis of mental diseases and mental deficiency of such a character as would qualify them for the position.

The list resulting from this examination will possibly be used for the next four years.

Modern Treatment and Preventive Medicine

A Compendium of Therapeutics and Prophylaxis, Original and Adapted

THE THERAPEUTICS OF A PHARMACOLOGIST.

By A. D. Bush, M. D.,

Professor of Pharmacology and Therapeutics, University of Southern California.

Forty-eighth Communication.

CYSTITIS.

Excluding the treatment of such cases as require surgical interference mention may be made of the more important therapeutic means for combating cystitis, and the underlying pharmacological basis.

Two leading indications are present: 1. To render the urine nonirritating and antibacterial; 2, to soothe the inflamed mucosa and alleviate the accompanying symptoms. To accomplish the first result it is necessary that all predisposing factors be rectified; next, the diet must be limited strictly to substances giving a minimum of possible irritants to the bloodstream, using milk for requisite protein and a simple carbohydrate like rice for energy. The patient will usually improve more rapidly if all food, other than water in abundance, is cut off for two or three days; moreover this plan will largely if not entirely obviate the time honored custom of giving alkalies for acid urine and boric acid or a benzoate for alkaline urine, either of which procedures complicates the situation while accomplishing little more than can be brought about by the water treatment.

When, in addition to this means of reducing possibly irritating constituents in the urine, it becomes necessary to make the urine antiseptic, either one of two drugs is available—salol or hexamethylenamine. In the intestines salol is broken up by lipase into salicylic acid and phenol; compound salts of these two products appear in the urine and manifest considerable inhibitory effect on bacteria anywhere along the urinary tract; but some renal irritation is liable to be induced during the process of excretion, lessening to that extent the value of the drug. Hexamethylenamine, during the process of its excretion from the kidneys, forms formaldehyde in the presence of acid urine, and this substance exerts a strong inhibitory effect on bacteria present in the tract. But if the urine is alkaline, no formaldehyde is formed; hence it becomes necessary, in using hexamethylenamine, to change an alkaline urine into an acid one, and for this purpose acid sodium phosphate is recommended. Care must be taken not to raise too high the percentage of available formaldehyde, since this preparation is itself an irritant to mucous membrane.

The best means for soothing the inflamed mucosa, thereby relieving vesical pain and tenesmus, consist of bladder irrigations. If the urine is alkaline, the irrigating fluid may well be a half strength boric acid solution; if the urine is acid, four per cent. of borax in a normal salt solution, with a small amount of glycerin added, may prove beneficial. In markedly acute cases, either of these preparations increases the distress; under such conditions we may advisedly substitute normal saline solution containing cocaine to the strength of 0.5 per cent.; this irrigation may be followed in about five minutes with a *freshly* prepared normal saline solution containing silver nitrate to the strength of from 0.5 to one per cent.; though in some cases a more effective irrigant than the silver nitrate solution is mercuric chloride in a one to 15,000 solution. In all these cases, the liquid serves as a mechanical means for washing out bacteria and other irritating products, while the contained medicament serves to stimulate regenerative processes. The method of gravity injection with siphonage removal gives most thorough irrigation, but great care must be exercised not to overdistend the bladder.

Great pain and tenesmus is most gratifyingly relieved by morphine; but we should place no dependence on any assumed local effect from morphine suppositories. Morphine exerts its narcotic effect chiefly on the brain, with scarcely any anesthesia of the sensory peripheral terminations.

Principles of Treatment in Fractures and Joint Wounds.—R. Lataste (*Paris médical,* October 28, 1916) discusses the postoperative treatment of wounds of the extremities, as encountered in military practice. The operation itself has for its purpose by opening up the wound, removal of blood, foreign bodies, and bone fragments, and judicious disinfection, to establish conditions under which the system can carry the combat against the local infection to a successful issue. The subsequently necessary immobilization to be effectual must permit of constant inspection and palpation of the limb, and be readily established and interrupted. A simple plaster apparatus, made from a long sheet of tarlatan eight, twelve, or sixteen layers thick, impregnated with plaster and water and applied as a gutter splint, gives best results in most cases, and is far superior to metallic gutters, which often do not properly immobilize. The wound itself should be covered with a smooth, comfortable, rather voluminous, but not too extensive dressing, and the plaster gutter applied over the dressing, with its edges turned back so as not to enclose more than one half the circumference of the limb. The gutter is held in place with a roller bandage, carefully applied with the limb in good position. For wounds near the shoulder the gutter is forked at its upper end; for the lower extremity, the gutter projects beyond the toes, the dorsum of the foot, however, remaining uncovered; for the knee, an inverted L shaped gutter is used, the shorter limb being fastened in front of the lower abdomen and pelvis. Such gutters can be quickly made and removed. At each dressing of the wound a new plaster apparatus is required, but its production requires only a few minutes, and furthermore, infrequency of wound dressing is, with immobil-

ization, a cardinal principle of the treatment, all dressings tending to traumatize fragile tissues, to open the way to further infection, and to fatigue the patient—as illustrated in the temperature chart, which shows a rise after every dressing. If everything goes well without any redressing, he dispenses with it. The local and systemic conditions are, however, constantly and carefully watched. If the patient begins to suffer more, or the temperature rises, he is redressed, not for therapeutic, but for diagnostic purposes—to find out why the initial operative treatment has not been completely successful. Pus in the dressings is disregarded. If the patient is doing well, the pus is *ipso facto* shown to be innocuous.

Glycerin and Ichthyol in Septic Wounds.—Thomas W. A. Daman (*British Medical Journal,* November 11, 1916) reports that in septic wounds in which the circulation has been much impaired or in which there has been much hard crusting healing progresses very slowly under the usual measures. This can be overcome by the application of solutions of ichthyol and glycerin of varying strengths. This combination provides an effective antiseptic which also softens the tissues, stimulates the circulation, and, through its hygroscopic properties, stimulates the exudation of serum rich in antibodies. It also diminishes the tendency to excessive scar formation, and accelerates the processes of granulation and epithelialization. The dressings should be applied night and morning, or often only once daily. Effects nearly as good can also be obtained from solutions of magnesium sulphate in water and glycerin, but the presence of the water tends to diminish the osmotic action of this dressing.

Memorandum on Tetanus.—The War Office Committee (*British Medical Journal,* November 11, 1916) state that there is no question of the value of the prophylactic use of antitetanus serum, but the time of its use and its repetition are of great importance. It should be injected at the earliest possible moment and, since it has been shown that the passive immunity which the prophylactic injection confers does not last, the injection should be repeated at intervals of seven days as long as necessary. Three or four injections at such intervals should be given in long continued septic military wounds. The prophylactic dose should be not less than 500 U. S. A. units, and should be injected subcutaneously. Before performing an operation upon a septic wound, or at the site of such a wound, a prophylactic dose should also be given if more than seven days have elapsed since the last preceding injection. Such a preoperative dose should be given two days before the time of operation if possible. In the treatment of suspected wounds such antiseptics as hydrogen peroxide, potassium permanganate, chlorine water, or solution of iodine should be given the preference owing to their special antagonism to the growth of tetanus bacilli. In the therapeutic use of antitetanus serum so short a time as half an hour is of importance, and should not be lost in the presence of symptoms. In order to give the dose as soon as possible we should be on the alert for signs of local tetanus in the form of muscular stiffness in the region of the wound. The serum should be given intrathecally, intramuscularly, and subcutaneously, all at the same time. The first to reach the toxin at the site of its action, the second to attack the circulating toxin at once, and the third to continue the neutralization of the toxin for a longer period of time, owing to its slower absorption. Not less than 3,000 units should be injected intraspinally, from 5,000 to 10,000 intramuscularly, and 3,000 to 5,000 subcutaneously. The intraspinal injections should be given daily for three to five days, and then discontinued. The others may be given daily for longer periods of time. Symptomatic treatment with morphine, bromides, chloral, chloretone, and paraldehyde is a useful adjunct to the specific treatment. Phenol injections, and magnesium sulphate have not yet been demonstrated to have special advantages, and the latter is too risky for general trial.

A Rose Irrigator for Wounds.—Almroth E. Wright, H. H. Tanner, and Ralph C. Matson (*Lancet,* November 11, 1916) describe in detail several forms of a so called rose irrigator for wounds. This form of irrigator consists in a thermos bottle to supply the irrigation fluid at the proper temperature, a tube containing a drop counter, and a connection containing a number of openings to which rubber tubes can be fitted. Through each of the outlet tubes a piece of wire should be run, fastened above, so as to keep the tube in position in relation to the wound. Into the upper end of each of the tubes a piece of gauze should be inserted to conduct the fluid into it at a uniform and slow rate. By means of this form of irrigator it is possible to supply a perfectly continuous irrigation of physiological solution over the whole area of a wound, at a uniform rate and temperature, irrespective of the size, shape, or locality of the wound. The precise details as to each of these matters, and the methods for their regulation are set forth in detail in the original paper.

Exophthalmic Goitre. — Hector Mackenzie (*Lancet,* November 11, 1916) states that he has employed about all of the remedies advocated, and has had little result from most of them. Bromides proved useful where nervous symptoms were very marked; belladonna seemed to quiet the heart and soothe the nervous system; opium was found of value when there was looseness of the bowels; and calcium salts and the phosphates seemed to be beneficial when there was progressive loss of weight. None of the glandular preparations proved of any special value in the author's hands, and the same was true of the various other preparations of a similar type such as thyroidectin, the milk of thyroidectomized goats, etc. Contrary to the reported results of others, even the use of x rays did not very materially benefit many of the patients. One striking case was an exception to this rule, for after several repeated courses of intensive x ray treatments her hyperthyroidism was transformed into hypothyroidism which responded well to the use of thyroid extract. It is possible that the general use of x rays has not been sufficiently intensive to produce results. His experience with operative treatment of exophthalmic goitre has also been unfavorable, and he is not able to fully subscribe to it.

Congenital Clubfoot.—I. Reitzfeld (*Medical Record,* Nov. 18, 1916) gives a report based on twenty-six cases, and states that treatment consists of three fundamental principles; correction, retention, and supervision. Correction is obtained by manipulation, and then maintained by fixation first with adhesive straps, later on with plaster of Paris which is changed every two or three weeks, and the same process repeated. Special types of talipes require certain special modifications. When correction has been obtained, massage, especially of the calf muscles, is instituted. The average time required for cure in all types of clubfoot is four months, although constant supervision is necessary for two or three years to guard against relapse.

Indications for Operations on the Stomach.—Julius Friedenwald (*Maryland Medical Journal,* November, 1916) gives the following indications for operation on the stomach: Obstruction whether at the pylorus or cardia is an indication. Gastrostomy is to be done in impermeable strictures of the cardiac orifice or esophagus. In benign obstruction the operations indicated are pyloroplasty, gastroenterostomy, or pylorectomy, while in malignant disease pylorectomy is to be done for cure, and gastroenterostomy for relief. In gastric or duodenal ulcer operation is to be considered only where there are complications or where the condition has resisted medical measures, and the operations are excision of the ulcer, pylorectomy, pyloroplasty, or gastroenterostomy. In gastric carcinoma there is only one cure and that is early operation and in doubtful cases exploratory incision.

Relief of Dysmenorrhea and Sterility by the Intrauterine Stem.—H. A. Royster (*Virginia Medical Semi-Monthly,* October 27, 1916) discusses in particular the treatment of the anteflexion type of dysmenorrhea, in which the pain comes on a few hours to a day before the flow, and is relieved as soon as free flow has been established. This class constitutes the majority of all cases. The patients are either young girls clamoring for relief from excruciating pain, or barren married women. Having made a probable diagnosis of anteflexion dysmenorrhea, he selects a day immediately after a menstrual period and examines the patient under ether. If anteflexion and no complications are found, dilatation, and in some instances curettage are performed and a stem is inserted—all under the strictest surgical technic. The patient remains in bed about a week, during which time measures are taken to correct improper modes of living and unhygienic habits. He insists that the stem shall remain in place over three menstrual periods, or even longer if necessary. The first period is usually as painful as before; the second should be less painful, and the third almost or quite free from pain If pain persists the stem can be safely left for a longer time, until a painless period occurs. Six months was the longest period in the series. Use of the stem for one or two weeks, as heretofore, is useless. Where the pain recurs some months later, the stem may again be introduced, perhaps without an anesthetic, after dilating the canal gradually with bougies. The Wiley stem, with distinctly bulbous tip and somewhat straighter than most other stems, gives best results. The author usually heats it in boiling water to bend it quite straight, thus correcting the anteflexion, slight anteflexion being normal. Of fifty-nine cases, treated in five years, forty-eight reported permanent relief from pain; in ten of these the procedure had been repeated. Of the remaining eleven cases five were improved and six unimproved. Cure of sterility resulted in sixteen women who had been married without issue for two to sixteen years before the beginning of the treatment.

Curative Treatment of Tetanus.—Bacri (*Bulletin de l'Académie de médecine,* October 24, 1916) reports that he has had such excellent results from repeated, massive doses of antitetanic serum, all patients recovering in his series of thirteen cases, that he is convinced of the curative power of this serum in all stages of the disease, irrespective of whether a prophylactic injection has previously been given. In eight of his cases no such injection had been made. The treatment recommended consists in daily subcutaneous injections of fifty to sixty c.c. of serum at one dose for six successive days. The total amount used in his own cases ranged from 160 c.c. in a case diagnosed early to 420 c.c. No marked serum symptoms, early or late, were noted. In nine cases a slight recrudescence of trismus was noticed in the twelve hours following the injections. The fever due to tetanus passed off by the sixth or seventh day at the latest. Generally by the third day after the beginning of treatment the course of the disease became much milder. Massive, repeated doses shortened the affection, enabled the patient to take food, and reduced or almost eliminated the period of convalescence. Although the serum proved curative at all stages, its use should preferably be started as soon as trismus appears and persisted in in spite of an apparently mild nature of the disease.

Malignant Edema.—F. McKelvey Bell (*Canadian Med. Assoc. Journal,* October, 1916) states that the treatment of malignant edema, or septic gangrene, must be radical and immediate in order to be useful. The term malignant edema seems to be unfortunate, for it may suggest anthrax to some minds, while the condition under discussion really is one of septic gangrene. Every hour lost increases the chance of death, out of all proportion to the apparent danger. Deep incisions four to six inches long are made down almost to the bone, avoiding the main arteries and nerves, and kept wide open. Several such incisions are made. The wounds are then irrigated with hydrogen peroxide, followed by a combination of this and of carbolic acid in equal parts, and packed lightly with gauze, left in just long enough to check bleeding. Dressing and irrigation are repeated every three hours. After the first dressing no gauze is left in the wound, but a thin layer is laid over the opening to exclude dust and flies. Closure of the wounds has to be prevented. While this disease is very rare in civil life it has proved to be comparatively common in military hospitals at the front. For rapidity of onset and disastrous effects it has few equals. Treatment should be instituted the moment the disease is suspected, without waiting for a bacteriological examination.

Red Mercuric Iodide Insoluble.—G. Frank Lydston (*Journal A. M. A.*, November 11, 1916) states that this salt is becoming widely used for intramuscular injection in solution in oil, but the fact is overlooked that when injected it is precipitated and is then no more soluble than calomel, or the salicylate of mercury. It apparently undergoes slow solution and absorption later. Athough it is precipitated by blood serum it may be injected intravenously in solution with potassium iodide, apparently without harm.

Tonsillectomies in Poliomyelitis.—Joseph C. Roper (*Long Island Medical Journal*, November, 1916) calls attention to the finding in the recent epidemic of a considerable group of cases in which there were localized foci of pus in the tonsils, from which the typical organisms could be isolated. In these cases the progress tended to be slow with more or less prolonged fever, and at times late development of paralysis. On the strength of the pathological and bacteriological findings the tonsils were removed from a group of such cases. In some of the removed tonsils similar foci were found, but not in all. Several of the patients thus treated showed marked benefit after the operation. The tonsils were never removed during the acute stage of the disease, but usually after the end of the third week.

Results of Auditory Reeducation with the Vowel Siren.—Marage (*Bulletin de l'Académie de médecine*, October 24, 1916) points out the advantages of treating traumatic deafness with the vowel siren rather than by the ordinary vocal method of auditory reeducation. This series of one hundred cases comprised twenty-one cases of traumatic cicatricial otitis media, all of which were relieved by his method; eleven of labyrinthine concussion, with nine relieved; fifty-nine of combined cicatricial otitis media and labyrinthine concussion, with forty-six relieved, and nine of nontraumatic organic deafness, with eight relieved. With Marage's instrument one physician unaided can treat in three months two hundred patients, whereas by the vocal method only six could be handled during this period.

The Internal Administration of Iodides and a New Albumin Combination of Iodine; Iodolactin.—M. A. Girshovitch (*Roussky Vratch*, July 30, 1916) calls attention to the fact that the internal administration of tincture of iodine is without therapeutic value, since very little iodine is absorbed. This fact he established by testing the urine for the presence of iodine. The urine is shaken with chloroform and nitric acid. In the presence of iodine the chloroform becomes pink, occasionally red. The urine of persons taking ten drops of the tincture three times daily for two weeks failed to show the presence of iodine. In an experiment on a cow, forty grams of metallic iodine suspended in oil was injected subcutaneously, and while marked local and constitutional symptoms appared, the milk was found free from iodine. This explains why the administration of tincture of iodine is not followed by iodism—a supposed advantage which is emphasized by the advocates of the internal use of the tincture in preference to the salts of iodine. As to the latter, absorption takes place very rapidly, as shown by the urine test. The author discusses the advantages of the various combinations of iodine with albumins or oils, and calls attention to a new combination of iodine-iodolactin, which is a product possessing all the qualities of the other organic combinations, but containing a larger proportion of iodine (fifteen per cent).

Intravenous Injection of Hypertonic Solutions of Glucose in Septicemia.—G. I. Boradulin (*Roussky Vratch*, August 27, 1916) states that he found by experience that intravenous injections of collargol and electrargol are more effective in the treatment of septicemia than polyvalent antistreptococcic serum. While overcoming the infection it is necessary to support the patient, particularly the heart's action. For this purpose he found that a thirty per cent. solution of glucose in water answers much better than the isotonic salt solution usually employed. From 250 to 300 c. c. may be injected at once, the fluid being introduced very slowly. This he regards as essential, and states that the operation should consume not less than one hour. The injection may be repeated two or three times a day for three or four days. The glucose acts as nutriment to the muscles, particularly the heart muscle, by supplying the glycogen which seems to be used up in the course of septic infection. This fact he demonstrated by experiments on two dogs in which suppurative peritonitis was induced. One of them received an intravenous injection of glucose solution. On the following day the dogs were killed, and the livers examined for glycogen. The dog that received the glucose showed glycogen in the liver, while the liver of the other was free from glycogen.

Treatment of Paralysis Following Acute Poliomyelitis.—John Joseph Nutt (*Long Island Medical Journal*, November, 1916) states that after the thirty-fifth day of the disease measures should be instituted for the care of the resulting paralysis. These should consist chiefly in the proper adjustment of braces which support the affected member, relieve the strain on the paralyzed or weakened muscles, and yet permit a certain amount of motion in the normal planes with adequate limitation of excessive motion caused by an unopposed normal muscle. The brace should be worn continuously with the exception of a period of two hours each day, during which it should be removed, and the child allowed freedom to move about on the floor or bed. At night a hot bath should be given, with or without the addition of sea salt, and while in it the child should be encouraged to move the affected member. The full range of each motion should be completed by the attendant at this time to prevent the formation of contractures. After the bath a session of muscle training should be given, and the brace then applied for the night. Massage should be employed with great caution, since if applied incorrectly or excessively it may do great damage. The various forms of mechanotherapy should not be used, and no surgical operation should be considered during the first two years after recovery from the acute attack.

Unsatisfactory Treatment of Chronic Bone and Joint Disease.—The treatment of tuberculous joint disease, observes the *Medical Press* for November 29, 1916, in children is sufficiently prolonged on occasion to break the heart of even the most enthusiastic surgeon. The patient is always an unwelcome arrival in the hospital ward, and it is precisely this fact that makes the disease so hard to treat properly. Many a little sufferer is sent home discharging copiously from sinuses who really should be kept for two years properly to eradicate the infection. In London the great infirmaries which stud the city are the homes where these poor victims can be always under medical care; but in Dublin, with its huge number of hospitals, there is no place, save the Unions, where a bed can be promised for an indefinite period. The awful scourge of tuberculosis is so foul a blot upon some of the fairest spots in the country that one cannot but wonder why, in the efforts which have been so perseveringly made in the last ten years to cope with it, provision has not been made for an aspect of the disease which every surgeon dreads. It would be the greatest of practical charities to institute hospitals, not for incurables, but for cases which cannot be thoroughly treated under the present system of hospital work. No one can blame the authorities in a hospital for looking askance at a case which meets the eye month after month, and sometimes for even a year. The institution of a proper refuge for a large and altogether pitiable part of our population is a work which should invite the sympathy and hearty cooperation of all who really mean to help in the fight against consumption. Till we have such a place no surgeon can even venture to predict a fair result to treatment of hips and bones.

A Treatment for Burns.—In this age of new methods for old troubles it is only fitting that the burn, that old enemy of dressers and nurses, should also have something new as regards its treatment. Dr. Barthe de Sandfort, of the St. Nicolas Hospital, Paris, has for some years been using paraffin, melted and at a temperature of from 80° to 100° C., in the treatment of ulcers and burns, and he now describes the method again and in more detail. It is quite simple, and consists in spraying the liquid over the burn and allowing it to cool. The paraffin, which may be mixed with some resin to give toughness, dries quickly, and a mask is thus formed under which the most surprising lymphocytosis occurs. This is followed, according to the *Medical Press* for November 29, 1916, by the appearance of small islets of epithelium, and the most gratifying result of the treatment lies in the rapid healing without the hideous scars which our more accustomed methods permit. The wound must be dressed at intervals determined by its severity, and the dressing consists in raising the wax from the wound and allowing a stream of peroxide to flow over the surface. The paraffin is again applied as before. The method has already been employed for some years, but it has not been heard much of in Great Britain. It presents no difficulties to surgeon or patients, and its painlessness is in strong contrast to the usual agony of the dressing of a large burn. The result is ideal from the cosmetic standpoint, and altogether the method deserves a trial at the hands of those who have been taught by bitter experience to dread above everything the familiar bad burn. The yellow stains of picric acid which ultimately bestow themselves all over the bed and clothes of the sufferer are no great attraction to the esthetic mind of the nurse, and by her as well as by the patient will the treatment be welcomed if its results are what they seem to have been in the St. Nicolas Hospital.

Prophylactic Immunization with Bacillus typhi exanthematici.—Harry Plotz, Peter K. Olitsky, and George Baehr. (*Journal A. M. A.*, November 25, 1916) state that although it has not been possible for military reasons to give actual figures concerning the epidemics of typhus fever in Serbia, Bulgaria, and Volhynia, they have been able to prove the marked protective value of prophylactic vaccination with Bacillus typhi exanthematici. Thus among a total of 8,420 persons vaccinated there were only six who manifested the disease, although those chosen for the vaccinations were hospital workers and others most exposed to the disease. In one town complete vaccination was carried out in four of the five military hospitals, and in these four no cases of the disease developed intramurally. In the one hospital in which no vaccinations had been made there were thirty-four house infections in the same period of time. The vaccination does not offer complete protection, but the degree of protection which it does give seems to be very great. The vaccine was of such strength that each mil contained about two billion killed organisms of fifteen different strains, and the doses were of half, one, and 1.5 mil at intervals of five or six days.

Course of Spread in Experimental Tuberculosis.—Kurt Ziegler (*Medizinische Klinik*, October 8, 1916) reports that by using strains of tubercle bacilli of very low virulence, and injecting them into different portions of the body in experimental animals he was able to follow the routes by which the disease spread, and found these to be the lymph channels and glands in all cases. He also found that the spread did not always occur in the same direction from a given primary focus, a fact which confirmed the belief of some investigators that lymph does not always flow in the same direction, but that its direction of flow is largely dependent upon the function of the several organs. When the inoculation was intraperitoneal or into the omentum the glands about the pancreas first took up the bacilli and the disease extended thence toward the liver or spleen, or both, and upward along the lymph vessels and glands, passing through the crura of the diaphragm into the chest. From there the bronchial glands were next involved. The infection of the parenchymatous viscera and the lungs occurred by the lymphatic channels, and never by way of the blood stream. Infection by way of the tonsils and cervical lymph glands passed upward to the submaxillary region, and downward to the mediastinal and hilum glands, or along the glands about the aorta down to its bifurcation and to the kidneys. Careful autopsy in a human case confirmed these findings, and he holds that spread of the disease through the blood stream occurs only in acute miliary tuberculosis.

Miscellany from Home and Foreign Journals

Effect of Salvarsan on the Blood Wassermann Reaction.—John T. King, Jr., (*Journal A. M. A.*, December 2, 1916) gives the quantitative effects of intensive salvarsan treatment in the different stages of syphilitic infection upon the Wassermann reaction in a series of cases, using a uniform technic. One primary case in a series of twenty in various stages showed a reduction in the strength of the reaction from the use of salvarsan, the others showing no change. Even in cases not previously treated there was often little tendency for the reaction to be weakened by salvarsan, although such cases often showed pronounced clinical improvement. Only one instance of an increase in the intensity of the reaction was observed to follow the administration of salvarsan. This increase appeared one hour after the administration, but the titre returned to the original level on the following day. This throws some doubt on the validity of the use of the so called provocative dose of salvarsan, and the results recorded in the literature may have been due to faults in the Wassermann technic employed. No marked spontaneous changes in the intensity of the reaction were observed to occur over short periods of time.

Experimental Endocarditis.—H. K. Detweiler and W. L. Robinson (*Journal A. M. A.*, December 2, 1916) report that from blood cultures taken by a modification of Rosenow's method strains of streptococci were obtained from cases of endocarditis which were of a lower degree of virulence than any heretofore described. These strains were then cultivated and found to belong to a Streptococcus viridans variety. Their cultural characteristics and morphology are described. They were employed for inoculation into rabbits to determine their virulence, and selective localizations. With these organisms it was possible to produce all grades from simple bacteremia without localization up to the most malignant forms of infective endocarditis. Some form of heart lesion due to the organisms was produced in nearly fifty-seven per cent. of all rabbits. Endocarditis provided forty per cent. of the lesions, pericarditis thirteen per cent., myocarditis six per cent., and aortitis three per cent.; there was absence of lesions of the heart in thirty per cent. These results indicated the marked property of these organisms to localize selectively in the heart tissues. The clinical picture and post mortem findings in the rabbits in which developed cardiac lesions were very closely similar to those observed in the human cases infected with the same organisms. Fever was seldom more than slight, often absent, and one animal showed subnormal temperature. The cardiac lesions were almost identical with those from human cases. It was observed in the experiments that, not only could this Streptococcus viridans produce all grades of endocarditis, but also every grade of endocarditis could be produced in different animals by the same strain of the organism. Some of the experimental animals successfully infected recovered, and the belief is expressed that the finding of Streptococcus viridans in the blood of a human patient should not be taken as a certain indication of a fatal outcome. Coupled with these observations made on organisms isolated from the blood of human patients there was an extensive series of similar observations made with strains of Streptococcus viridans isolated from the mouths and tonsils of normal persons. These strains were found to be of very low grade of virulence and to locate specifically in the heart tissues to almost as great an extent, but in four instances they also showed an affinity for the joint tissues. This phenomenon might be explained, either on the hypothesis of the organisms having a dual affinity, or upon the theory that in some instances two types were present in a single culture. These observations, taken together, showed that the organisms isolated from the oral cavities of apparently normal persons have the same selective affinities, and the same degree of virulence as those obtained from the blood of persons ill with endocarditis.

Laboratory Diagnosis of Typhoid Infection.—A. Demolon (*Paris médical*, October 21, 1916) asserts that while the practice of antityphoid vaccination undoubtedly complicates the interpretation of the typhoid laboratory diagnostic tests, our aim should be, not to discard these tests, but to ascertain precisely the significance of the results they yield under different conditions. The blood culture method should be applied early in the case. In subjects previously vaccinated against typhoid it will usually give a positive result in the serious cases, though often negative in mild ones. The practitioner can easily carry it out himself by providing himself in the laboratory with a sterile syringe for venous puncture and a special receptacle containing an appropriate culture medium. Demolon uses a culture tube containing ten c. c. of ox bile (previously heated to boiling); to this five or six c. c. of the blood obtained from the patient are added. No peptone is used. To get rid of the skin staphylococci sometimes contaminating the culture because of insufficient skin disinfection, he passes the product of the blood bile culture through phenol bouillon at 37° to 38° C. for six or eight hours before transferring the culture to an agar slant. The blood culture failing to solve the diagnostic problem in certain cases, he resorts also to the Widal agglutination test, having previously carefully ascertained, however, the results obtained by a definite agglutination procedure in healthy vaccinated subjects. The usual one hour microscopic method is always used. In performing the test he much prefers to employ a young, virulent culture of typhoid bacilli rather than an old, heated, or attenuated culture, the results being much more definite with the former. In many vaccinated typhoid cases an immediate diagnostic conclusion can be reached from the agglutination reaction Thus, where a positive reaction in a one in fifty dilution is obtained, in conjunction with clinical signs of typhoid, a diagnosis of typhoid is warranted—especially if, after a negative test at the outset, the second test a week later is positive. When

a paratyphoid condition exists, agglutination of one of the paratyphoid organisms in a suggestively high dilution, such as one in five hundred, will usually be noted; if not, the discrepancy may appear a few days later. When a mixed typhoid, paratyphoid A, and paratyphoid B vaccine has been administered, the physician will often be left in doubt by the agglutination test until a new, more accurate system of interpretation has been developed.

Renal Function in Pernicious Anemia.—H. A. Christian (*Archives of Internal Medicine*, October, 1916) reports observations in fourteen cases showing that in a severe anemia renal function, as measured by the dietary test of Hedinger and Schlayer, is disturbed in much the same way as in advanced chronic nephritis. The disorder of excretion seems to be either a nutritional or a toxic disturbance in renal cellular activity. There is no other evidence of chronic nephritis in these cases, and the disturbance decreases with improvement in the anemia, unless the latter is so persistent as to lead to a permanent disturbance of renal function.

Two Cases of Splenectomy for Banti's Disease.—W. F. Cholmeley (*British Journal of Children's Diseases*, November, 1916) reports two cases in which he performed splenectomy for Banti's disease in children. One case presented the typical lemon yellow tint of the skin with slight icteric tinge of conjunctivæ. These symptoms, which in an adult suggest pernicious anemia, usually point to Banti's disease in children. X rays and arsenic, which seem to help cases of lymphadenoma and leucemia, do not benefit Banti's disease, whereas splenectomy acts like a charm. The huge blood destroying organ is removed, and excessive hematolysis stops at once.

Acute Mammary Carcinoma.—S. C. McCoy (*Lancet-Clinic*, November 18, 1916) believes this condition is less rare than was formerly supposed. Both scirrhous and medullary varieties of carcinoma have been observed. The condition begins suddenly, usually as a diffuse process, the entire gland being enlarged, firm, and painful, though occasionally as a small nodule, or indurated mass. Fluctuation may or may not be noticed on palpation. The skin is edematous, reddened, and usually assumes the orange or pigskin appearance; the subcutaneous veins are sometimes enlarged, the nipple is sometimes retracted, and local and general elevation of temperature is the rule. The infiltrated skin may show small abscesses and necrotic areas. Early axillary and supraclavicular gland involvement, with general or regional metastases, occurs. Cachexia and toxemia are likewise promptly manifested, and death may ensue in a few weeks or months. The greatest diagnostic difficulty lies in the differentiation from acute suppurative mastitis. This may even be impossible before operation, unless a section of tissue is microscopically examined. The temperature is usually lower in acute cancer than in mastitis, the inflammation more diffuse, and the skin more extensively involved, brawny, and adherent. Early lymphatic involvement may occur in either affection. In his case, that of a robust woman aged fifty-two years, the condition was, for a time, mistaken for mastitis. Profound toxemia developed and death—operation being inadvisable—took place within ninety days. Brief accounts of twelve cases previously recorded in the literature are given. Apparently pregnancy and lactation have no especial relationship to the condition. He issues warning that whenever a diagnosis of mastitis is made, if the inflammatory symptoms fail to improve under appropriate treatment, acute carcinoma should be suspected. Even where the clinical diagnosis of acute carcinoma has come to appear certain, prompt radical excision may still offer some hope for prolongation of life.

The Teeth in Rickets.—J. Lawson Dick (*British Journal of Children's Diseases*, November, 1916) reports that in an examination of 1,000 school children in the East End district of London he found eighty per cent. of them showed evidence of rickets in their teeth. The great majority of the children were of Jewish parentage. Rickets is due to a defect in calcium metabolism and shows itself particularly in the teeth. Like syphilis, the condition is found especially in the permanent teeth. The teeth commonly affected are the central and lateral incisors, the tips of the canines, and the crown of the first molars. Of cases showing caries of the teeth, the lower first molar was decayed in eighty per cent., the upper first molar in thirty per cent., one or more lower premolars in thirty per cent., and one or more upper premolars in 12.5 per cent.

Rapidity of Hormone Formation in the Thyroid Gland.—David Marine and J. M. Rogoff (*Journal of Pharmacology and Experimental Therapeutics*, October, 1916) report a study of the psysiological effects on tadpoles of thyroid tissue removed from dogs at definite intervals after the intravenous injection of fifty mgm. of potassium iodide. A comparison of these results is made with the changes in the dogs' thyroid tissue following such injections, viz., an increase in stainable colloid material and a shrinkage in the gland cells, usually quite evident thirty-six hours after the iodide administration, and sometimes beginning within twenty hours. It was found that differences in the effects of the control and iodized thyroid lobes on the tadpoles could be detected as early as the eighth hour, but became marked only by the twentieth hour. Thus, the thyroid tissue changes observed seem closely related to the elaboration of the iodine containing hormone of the thyroid. Whereas the storage of iodine in the thyroid from iodides is, as has been already shown, practically instantaneous, the production of the hormone is relatively slow. After thirty hours only a small fraction of the iodine taken up in as many seconds is transformed into the specific hormone. Variations in the rate of hormone formation in different patients, and the normal occurrence of iodine in the thyroid in both an active and an inactive form, not only explain the varying reactions of exophthalmic or simple goitre cases to iodine administration, but also suggest the importance of the chemical nucleus or mother substance with which iodine, in becoming activated, is combined in the thyroid. This mother substance is known to contain an aromatic nucleus, and may be a tyrosin or tryptophane derivative.

Proceedings of National and Local Societies

MEDICAL SOCIETY OF THE STATE OF NEW YORK.

Stated Meeting, Held November 23, 1916.

COMMITTEE ON MEDICAL ECONOMICS.

Chairman's Address.—Dr. SAMUEL J. KOPETZKY said that this meeting had been called for a discussion of the insurance bill introduced in the New York Legislature by Senator Mills and in other States, notably in Massachusetts and California. The medical aspect had been so much revised and improved over what was in the original bill that it was time to submit the plan to the medical profession for study and amendment. The medical provisions of the proposed act were fully outlined in a booklet issued by the Committee on Social Insurance of the American Association for Labor Legislation at 131 East Twenty-third street, New York, in November, 1916. In this scheme medical supervision and representation were adequately presented.

If the proposed panel system was chosen, any legally qualified physician could join and the insured were to have free choice. In some districts the funds could provide medical care through other methods, such as salaried physicians among whom there should be reasonably free choice. The limitation of the number of insured patients whom a physician might treat went far toward preventing the larger part of the population of a town being treated by any one physician; moreover, it prevented overwork of the physicians. It was desirable to separate the duty of certifying persons as eligible for cash benefit from that of treating him, and for this and for supervisory purposes a fund might employ a medical officer.

There were two proposed methods of paying the physicians, the capitation payment, or so much a person per annum, and the payment by salary. A third method was possible; a compromise between salary and capitation, by which a total sum, calculated on the per capita basis, was distributed among physicians in accordance with the services rendered by each. A fee schedule could be made whereby a physician was paid pro rata for office or house visits. Whichever system was adopted, all medical service to the insured would be paid for including the dispensary practice which today was unremunerated.

Representation of the medical point of view was accomplished by the presence of a physician on the Social Service Commission, and by provision for consultation with representatives of the medical profession on medical matters. This secured a hearing to the medical point of view on both State and local problems. The necessary supervision could be obtained through medical officers employed by the funds, while matters in dispute might be referred to special committees, both State and local. To these committees, representing the various interests, power might be given to remove undesirable physicians from insurance practice, subject to an appeal to the commissioner. The minimum benefits to the insured were hospital, medical, surgical, and nursing attendance for twenty-six weeks, medicines and surgical supplies, not exceeding $50 in any one year, cash benefits, maternity benefits, and funeral benefit.

The proposed act provided for local medical committees. The Commissioner of Health, or local health officer, appointed a member of his staff, who would be a physician, as a member of the local medical committee of each district within his jurisdiction. The other members of the committee would be elected by the physicians on the panel of the funds of the district and by the staffs of the hospitals which had made agreement with a fund in the district to treat the insured members. The committee would elect its own officers and serve without compensation. It would pass on all matters affecting medical benefit made by the boards of directors of the funds of the district, also on any dispute in regard to the medical benefit, or any charge made against a physician because of his work for a fund. If the committee and the board of directors did not agree, the matter would be referred to an arbitration committee. One or more medical officers would be appointed by each fund which would pay them; they would be removed only upon charges and after hearing by the board of directors. The medical officer alone would have authority to issue a certificate of disability, and only after personal examination of the applicant, and after being recommended by the attending physician.

Health Insurance and Preventive Medicine.—Dr. B. S. WARREN, of the United States Public Health Service, said that sickness insurance presented to its advocates various possibilities, depending on the angle from which they approached the subject. The employer saw in it an increase in labor efficiency and a stabilizing force; the employee saw in it relief in sickness to him and his; the physician saw it as a remedy for unpaid doctor's bills; the economist saw a basis for cooperation in other fields, and a remedy for industrial unrest; the public saw a relief measure which lessened the need for so much charity; the health official saw a measure for the prevention of disease. All advocates realized the possibilities for promoting health.

These measures were proposed as health measures, but not one provision had been made for the employment of health experts, nor any authority provided for spending any part of the funds for disease prevention, although the State was expected to pay one fifth of the funds in addition to the expense of supervision. No provision was made for membership of health experts on any of the directing or supervising bodies. The administration and control were vested in local boards composed of employers and employees with supervision by a State commission on which no provision was made for a doctor of public health.

Preventive medicine now constituted a special field of medicine and the general practitioner was

no more fitted to practise in this field without special training than he would be to practise surgery without special training. To public health officials, then, the question naturally arose as to what additions and amendments were required to make the proposed measures directly preventive of disease as well as measures for adequate financial and medical relief of sickness.

As the States were already paying for departments organized for the prevention of disease, it seemed best to utilize these existing agencies rather than create new and independent ones. In States where the health departments were efficiently organized, it would be easy to extend their operations into this new field of public service. Furthermore, in those possessing inefficient health departments, the building up of such would be wiser than placing upon the State the burden of maintaining two health agencies, each operating independently of the other. This was considered a serious objection at the last Annual Conference of State and Territorial Health Authorities with the United States Public Health Service, held in Washington, D. C., May 13, 1916, as was evidenced by the report of the Standing Committee on Health Insurance adopted by the Conference. It was proposed that the coordination of the work of the health insurance system with the public health machinery should be effected. The following plan was suggested:

1. Make the State Commissioner of Health ex officio a member of the State Health Insurance Commission.

2. Detail a medical director from the State Health Department to assist the commissioner to supervise the administration of the medical benefits, and to act as health advisor and director.

3. Detail district medical directors from the State Health Department to aid in the administration of the medical benefits in their respective districts.

4. Detail from the State Health Department a sufficient number of local medical officers to act as medical referees, sign all disability certificates, and to perform such other duties authorized by law or regulation. This would provide a health machine composed of a corps of trained sanitarians subject to central control and direction.

It would require one medical referee to every 4,000 insured persons. In a State with 1,000,000 wage earners, this would mean 250 local medical officers giving their entire time to the study of the health of the insured persons. This would be in addition to the treatment furnished by the panel physicians. The only additional expense incurred by this plan would be for the medical director and the district medical directors, as all the measures now advocated provided for medical referees. The medical referees would more than save their salaries in the disallowance of unfair claims.

It was proposed that these officers be selected according to civil service methods, their qualifications to be based upon their knowledge of preventive as well as of clinical medicine, and their term of office to be made permanent after a probationary period, subject to removal only for inefficiency or immoral conduct.

Some of the advantages of this plan would lie, 1, in the superior class of men selected as State officials by examination, attracted by the prestige of State appointment and permanent tenure of office; 2, the elimination of local influence of any sort by interchange of station; 3, the completeness and accuracy of statistics; 4, extension of laboratory facilities; 5, patient's free choice of physician or surgeon receiving payment on capitation basis, regardless of whether the patient was sick or well, after the manner of the English National Insurance Act; 6, in the directly preventive character of the work of medical officers.

From the foregoing considerations it seemed clear that a close correlation of the health insurance system with State, municipal, and local health agencies would be effected by the plan outlined and that the disease preventing efficiency of both would be greatly increased. The medical referees would be selected, appointed, and supervised by the State. The State and district health departments would also be represented in the administration of the health insurance system. The organized, centrally supervised corps of State medical referees would be a part of the health administration of the State. They would be local health officers with a distinct and definite field. In large centres a division of the labor of the municipal health officers and the health insurance medical officers might be made so as to avoid conflict of duties. It was a well known fact that in many industrial cities and towns the sections occupied by wage earners, especially the poorly paid, were most neglected from the standjoint of public health. The contribution to preventive medicine and to public health work which the intimate knowledge daily gained by the visits of trained satitarians into the homes of wage earners would afford, would be almost incalculable. Only by such methods would the disease causing conditions, such as housing, congestion, unsanitary conditions, diet, etc., be regulated.

If a State health insurance measure, designed to affect a very large proportion of the public, undertook to be preventive at all, it should expect of the State that the State's own machinery for exercising this function be used to its fullest extent in direct and close coordination with the health insurance machinery for distributing the cost of sickness.

The Labor Man's Point of View.—Doctor KOPETZKY stated that although Mr. HUGH FRAYNE, of the American Federation of Labor, National Civic Federation, was not able to be present at this meeting to explain the point of view of the workmen, it was nevertheless understood that the American Federation of Labor did not object to health insurance, but to its being made compulsory. This meeting was to be considered an open forum for the consideration of this point of view as well as others.

Compulsory Health Insurance from the Practitioner's Viewpoint.—This paper, by Dr. EDEN V. DELPHEY, appears on page 1191 of this issue of the JOURNAL.

Mr. MILES M. DAWSON, insurance expert, was glad he had come early to hear these addresses of

Doctor Warren and Doctor Delphey. His own remarks would be in explanation of the advantages of compulsory health insurance, which was intended to protect the workman against anything that was likely to disable him. It had not proved practicable in any country to levy a tax for compulsory insurance of the entire population; if it was to be a contributory form of insurance, it would not be practicable in this country except for wage earners and salaried employees. One was always suspicious when it was proposed to undertake something that had never been undertaken before, or, if undertaken, had failed. But a plan which had been successful in other countries for twenty-five years could succeed in this country.

The Committee on Social Insurance was composed of people devoted for several years to different phases of the subject, and the draft of the proposed act, now up for discussion at this meeting, was the third draft of the bill proposed by them. It was still capable of improvements which it was hoped would be made.

The advantages that it offered were: 1. Instead of being compelled when ill to resort to patent medicines or to go to a dispensary, under this law every insured person and his family would be able to get medical and surgical attention, nursing, medicine, and sickroom supplies for twenty-six weeks of disability and, if necessary, hospital treatment, and the advice of specialists. It presented a solution to the medical profession of the problem of doing away with quackery, and with free dispensary services to people who were able to pay for them.

2. This health insurance law would bring to the insured when ill, after the first week, a sum of money equal to two thirds of the wages he received, and this would continue for the period of disability, not exceeding twenty-six weeks.

3. Medical attendance of the family was assured, also the lying-in of the wife so that the child would be brought into the world under the best conditions afforded by a well organized medical system. These were very real advantages to the workman, and he was expected to pay two fifths of the entire cost in premiums. At the present time workmen paid the entire cost and in a most expensive way, by neglect, by the pauperization of his family, or by paying, at a higher rate, for the services he secured.

There were several advantages of the proposed system of insurance to the employer of labor. It had been proved in Germany that the average duration of the lives of males was extended from thirty-six to forty-eight years in a period during which sickness insurance was introduced. No men were working who were not in condition to work; this meant greater efficiency, more work, better work, and more years in which to work. The workman when ill was promptly treated, and brought back to full capacity in the shortest possible time. The workman also lived under proper sanitary and hygienic conditions which tended to increase his efficiency.

The physician should have the most vital interest in this matter, for he had at heart the welfare of those he served. He would be engaged in prophylactic as well as therapeutic work to which his entire attention could be devoted, leaving his mind relieved of the old anxiety of providing for his own family with so many of his bills unpaid. He would be paid out of an assured fund for every service he rendered. Neither in Great Britain nor in Germany had the medical profession suffered through the introduction of health insurance. No system of health insurance in this country would be introduced which did not provide for panel physicians and for free choice of the insured among them, but for the sake of the physician himself as well as his brother practitioners he would be limited to a certain number of patients a year.

The speaker found himself very much in sympathy with many of the statements in Doctor Warren's address. But to introduce a State public health officer as the absolute arbiter concerning the payment of claims, as he would seem to have suggested, would be a mistake. There were many public officials who did not care to do much work, and many received appointments through influence, not merit, and could not be removed for inefficiency. It was necessary to have a medical officer of these funds who could be removed by the management. If some method could be found to benefit by cooperating with the health department without taking away the control of the funds from the insurance management, it would doubtless meet the approval of the entire country. Perhaps making the medical referees also health officers, ex officio, for certain duties would effect both purposes.

Lee K. Frankel, Esq., Ph.D., sixth vice-president of a prominent life insurance company, said that the general subject of health insurance was too broad to be covered in the brief time allotted to him. It seemed to him that very careful consideration should be given to the proposed legislation before it could be approved. He had given consideration to the "model bill" and some of its provisions were still indefinite. Few of the men who would be affected by it really knew what was meant by social insurance. Anyone who had followed the development of sickness insurance in Germany knew that there was no more ignominious page in the social history of that country than the conflict which had gone on for nearly thirty years between the medical profession and the sickness insurance carriers. One reason was the failure of German legislation to recognize a fundamental insurance principle. Basically, insurance was replacement of loss, and in the case of sickness insurance it was replacement of wages lost through illness.

Any proposed legislation in the United States must recognize that the physician's relation to any sickness insurance scheme must place him in a position of dignity and must not subject him to temptation. Not only his professional standing should be assured, but his self respect must be preserved. Under the German scheme the same physician was counsel for both plaintiff and defendant; advocate for both the insured and the insurance carrier. While the physician was expected to act justly toward the insurance carrier, he was frequently expected by the insured to certify him for benefits to which the physician knew he was not entitled; refusal to meet the wishes of the insured frequently meant loss of good will. The serious situation in Germany was indicated by the fact that the physi-

cians were compelled to organize themselves to resist the insurance carriers.

If a proper scheme was to be developed in the United States, the carrier who paid the cash benefit should be divorced from the organization which gave sick care. The insurance carrier should do but one thing: that was, pay the cash indemnity. A separate organization should take up the problem of giving medical care to the insured, not only when he was disabled, but along the broader lines of prevention which would give the insured advice at any time, well or ill. Under such a scheme, medical, surgical, and nursing attendance would not be limited to twenty-six weeks, but would be given as long as necessary.

In Germany, insurance developed before the era of preventive medicine. Koch's bacillus was discovered subsequent to the introduction of the sickness insurance scheme. For this reason in Germany preventive medicine had always been the handmaid of insurance. In the United States a great health campaign had been developed, even in the absence of sickness insurance. The development in the United States would probably show the need of a centralized organization which should work along preventive lines and whose primary purpose would be to reduce the hazard of preventable diseases.

The speaker was of the impression that the subject was too large to settle in a few hours' discussion. There were many interests to be considered: those of the workman, the manufacturer, the physician, and in particular the public. It was important to forget acrimony, irritation, and recrimination. The various parties in interest should get together, discuss the subject from every possible angle, and finally submit a bill to the Legislature which would satisfy all parties and really mean something in the development of health insurance for the people of the United States.

Dr. Alexander Lambert did not consider advisable at this time Doctor Warren's idea of giving the entire control of health insurance to the Public Health Service or the State Department of Health in any given State because it would mean that these departments would absolutely control, not only health insurance, but the entire medical profession and their practice. Doctor Warren had stated that the average practitioner was not able, from his present training, to be a competent health officer. That was undoubtedly true, but the average health officer was just as incompetent to be a referee in medical and surgical matters; this brought matters to an impasse, each man being at present incompetent for the other man's job.

There must in any health insurance scheme be a blending of the ordinary clinical duties of the physicians and the duties of public health officers. Whether it was sufficient that the health department should have advisory representation on the board under the commissioners of health insurance, would have to be worked out. There was no reason under health insurance why the present laws regarding the report to the health department of all communicable diseases should not be carried out. This scheme of health insurance did not in any way abrogate the control of public health by health departments. While a blending of the health department and health insurance under the health commissioners was not only a desirable but a necessary thing, the absolute domination of the health department over the whole thing was not necessary, and this was the mistake contained in Doctor Warren's scheme.

As to the medical referees, they were considered an absolute necessity. The medical care of the patient must be divorced from the duty of deciding when a man was fit for work. The lack of appreciation of this fact was one of the great mistakes in the health insurance schemes abroad, both in England and Germany, and while it might be perfectly true that they did not care to copy in this country everything in the English and German schemes, a wise man certainly could learn from the mistakes of others. Both countries had found that medical referees were a necessity, and in Doctor Warren's plan it was the medical referee appointed by the health department who would dominate the whole situation over everyone.

(*To be concluded.*)

THE MEDICAL ASSOCIATION OF THE GREATER CITY OF NEW YORK.

Stated Meeting Held at the Academy of Medicine, March 20, 1916.

The President, Dr. Thomas S. Southworth, in the Chair.

GRIPPE AND ALLIED INFECTIOUS CONDITIONS.

Bacteriology of Grippe.—Dr. James Garfield Dwyer, of New York, said that they must keep in mind some of the main characteristics of the influenza organism in order to understand how it operated. The organism was present in large numbers in the sputum early in the disease and could be easily isolated, but in the later stages it was much harder to demonstrate or cultivate. It was an organism, moreover, that produced intensely toxic symptoms, acting in a similar way to the diphtheria bacillus. It did not usually call forth a leucocytosis. The report of the investigation by the local board of health showed that the influenza bacillus was isolated in only a small proportion of the cases, and that the organisms found most frequently were the ordinary pyogenic cocci. In the light of the clinical course of these cases, it was difficult to believe that the condition was due to organisms that they usually found in the nose and throat, especially when they remembered the intensely toxic nature of the condition. Moreover, the respiratory complications were rather of the bronchopneumonic type, contrary to that found in the ordinary pneumococcus and pneumococcus mucosa types. They were either dealing with an epidemic due to the influenza organism or they were dealing with one due to some causal organism not yet identified. The whole condition might be likened to that of scarlet fever, in which they always had the streptococcus but not as the causal factor. If the disease was due to the influenza organism, they knew that the latter was very easily killed off by drying, and that in the moist state, in sputum, etc., it remained alive for much longer periods; hence the spread by sneezing, coughing, and expectoration.

Probably the most important point to be emphasized bacteriologically was the value of serum or vaccine treatment.

Pulmonary Complications of Grippe.—Dr. Harlow Brooks, of New York, said that the frequency of pneumonia this year as a complication in what had been called influenza was known to all, but in the earlier epidemic he had found it more frequent than in the one in which they had just been participating; the fatalities also had been heavier in the earlier epidemic. In the one they were now passing through, the prognosis seemed to be better; all of the cases were milder from the outset, and most of them were cured unless complicated by other conditions, such as lung abscess, empyema, etc. Usually the first disturbance was a pharyngitis or tonsillitis, which gave very little trouble at first, but which on examination was evidently followed by a laryngitis, and this often by bronchitis. At any step in this chain the case might fall out and end in recovery without the complication. Practically all of the cases of pneumonia had had some additional and predisposing factor, as exposure, overwork, dissipation, or something of the sort. He had had no pneumonia develop in any of the cases where he had been able to persuade the patients to go to bed and live an invalid life from the outset for a few days. The predisposing conditions apparently formed a very important factor.

The onset was sharp, with fever, chill, and great prostration, more extreme than ordinary; as in the onset of bronchial pneumonia in adults, the signs of the bronchopneumonia soon developed; the bronchopneumonic signs might, however, disappear altogether and reappear elsewhere, either that, or a massing of the foci took place, and in many instances, especially those that went the wrong way, this massing was so great that the cases took on the physical characteristics of lobar pneumonia. In nearly all the cases which he had seen, this massing of the foci occurred and nearly all the cases which went bad developed it. A pleurisy also occurred, usually with a small amount of exudate, but the fibrin was of a particularly tenacious character.

The leucocytosis was high at first; later, the leucocytosis would fall and become a matter of 10,000 or 12,000, even though the case was active; the fall in the leucocytosis was not a measure of the lack of resistance of the patient. It would seem that for some reason they ceased to be formed in large amounts, and there was a fall of the polymorphonuclears. Often a true nephritis developed, but only in cases in which some faulty condition of the kidney had been present. The chlorides were present at the outset and apparently were not appreciably reduced until the massing of the foci and exudate took place. The sputum in the early stage was tenacious, abundant, and extremely sticky, so that shreds would lodge across the bronchi and remain some time; and at post mortem they would find big shreds of tenacious mucus, sometimes covered with fibrous, desquamated cells and mucus.

A striking characteristic was the appearance of blood in the sputum. In most of the instances in which he had been able to follow out this condition bacteriologically, Streptococcus haemolyticus was found. Only in cases in which the massing of the peri bronchial exudate was very marked did rusty sputum appear. A few cases terminated by crisis, but the others recovered by lysis. Sometimes the process lessened and then returned perhaps in a new area. The fully developed cases frequently looked like typical lobar pneumonia cases.

The bacteriology, followed in the ordinary clinical way, was interesting. In only a few cases was it possible to demonstrate the influenza bacillus; they might have been present but not demonstrable, even where injections of bouillon were made into the lungs and withdrawn the germs found were mostly the streptococcus, the streptococcus hæmolyticus, and the pneumococcus.

Doctor Brooks could not help thinking that in this epidemic the chief features were not due to the toxins of the pneumococcus; it seemed like a different thing from the pneumococcus infection, and judging from the organisms found, the streptococcus almost always predominated. He could not help feeling that the pneumococcus was not the main criminal in these infections. Bronchopneumonia, becoming massed into lobar pneumonia, but always definitely bronchial in extension, was the typical picture at post mortem, with tenacious exudate and the characteristic pneumonic foci. In many cases the bronchi became literally filled, but it was a tenacious fibrin containing many cells and much desquamated epithelium. The fibrinopus was so dense that they had to use considerable force to get it out of the bronchus. This would explain why so many cases became complicated with empyema; pleurisy was almost constant; very frequently it became an empyema. Pulmonary abscess obtained more frequently than ever before. Most of the abscesses were situated in the upper lobe near the apex, and were therefore easy to diagnose; and the prognosis was more favorable than in ordinary pulmonary abscess. Encysted empyema had been very common.

Medical Treatment of Grippe.—Dr. Reynold Webb Wilcox, of New York, observed that influenza differed largely from other diseases in that it seemed impossible to get specific medication from an antitoxin (which was the most likely, reasoning from the analogy to diphtheria) or in the form of a vaccine—so that the treatment of influenza usually resolved itself largely into the treatment of its complications. The laboratory workers were correct when they said that the bacillus of Pfeiffer was found with comparative ease early in the disease, and with difficulty later. Coming to the varieties of the disease, which had been classical for the past hundred years, they found the same indications for the treatment of influenza both as a specific and as a special treatment. The treatment in the three main clinical forms should be the same; but experience, since the epidemic of 1713, had proved that it was not. This season, the intestinal form had not been met with very frequently, but high intestinal irrigations preceded by calomel, and later, phenolphthalein, cleared up matters very quickly. But not one of these agents was directed toward the influ-

enza bacillus itself, excepting so far as high intestinal irrigations promoted the excretion of toxins and stimulated the heart.

If they took the neuromuscular type they found the same thing; they knew that the salicylates caused marked relief of pain; they knew that the pains of influenza were relieved by gelsemium; here again they were attacking the problem from a different standpoint. They knew also that quinine, with or without monobromated camphor, would relieve very speedily the muscular pain of influenza.

When they came to the most frequent of complications, the pulmonary, which predominated even in the epidemic of 1713, they found out something of value from the pathological side, but they still fell back on their clinical experience.

If they had received no other information than that given by Dr. Harlow Brooks in his masterly report on post mortem findings, their time was well rewarded. That had been to the effect that the largest number of instances of influenza had been of the respiratory form, the so called catarrhal form, and they had given the greatest trouble. Many who thought they knew something of respiratory troubles, and something of the treatment of pneumonia had had their confidence rudely shattered during this last epidemic.

Doctor Wilcox said that the patients whom he saw were mostly those to whom he was called in consultation by their physicians and had undoubtedly the most serious forms, and therefore his prognosis might be more sombre than it should be, but all internists admitted that the mortality of the influenza complications this year had been remarkable, and those who had studied every form of pneumonia treatment had admitted their chagrin by saying that the type of pneumonia was more severe this year, which was a confession, at least.

Creosote carbonate had yielded better results in the respiratory diseases following influenza than anything else he had seen; in massive doses, of course. Whether they accepted the classification which Cole had given, that Class 3 contained the pneumonias with fifty per cent. mortality (which the clinician doubted); and that Class 2 figured larger with a better mortality, they would be fortunate in getting patients of Class 4—which would be very satisfactory if they could make their clinical picture agree with the laboratory. As a matter of fact, it did not make much difference what kind of pneumonia a man got, but it did make a tremendous difference what kind of a man got that particular pneumonia.

Those who had studied the mortality rate of public hospitals found that it had not varied much in the past half century, and inferred that their treatment had not been more efficient. The hospital pauper suffered from cardiac and vascular diseases, and from renal degeneration just as he did fifty years ago, and was undoubtedly more alcoholic, and this accounted for the mortality. The treatment of pneumonia had improved, but the hospital patient had become a worse subject.

It was the February and March respiratory diseases that are so frequently fatal, owing to the strain incident to business and social activities and, in many instances, dissipation of all sorts. That had been the cause of the marked fatality which Doctor Emerson had shown.

Grippe from the Community Standpoint.—Dr. Haven Emerson, Commissioner of Health, New York City, said that before allowing the impression to gain permanent foothold, that they had been dealing with an epidemic of influenza, it was well to consider that they had to date no facts indicating that more than a very small percentage of cases of acute respiratory disease, seen in the past three months, were due to the influenza bacillus. No confirmation of the suspicion that Bacillus influenzæ was the main etiological factor reached him as the result of inquiry among laboratories and physicians of New York, Boston, and Philadelphia.

It was largely a question of the virulence of the infection and the massiveness of the dose, the conditions of exposure, and the resistance of the individual, and if there was a combination of these, as we found in the winter season, when there was a diminished resistance, a crowding in public places of amusement, and overwork that continued day after day, they got all the maximum conditions favoring the dissemination of disease; and until the physicians taught their patients who had acute respiratory infections that they were dangerous to the community as carriers of an infectious disease there would be very little improvement in these conditions. This was an annual event, and this was the regular season for it, as in previous years.

The epidemic of infectious colds was, as had been reported in the *Weekly Bulletin* of the department, due to the presence of the pneumococcus-streptococcus group and the organisms common in the mouth and upper respiratory tract. Between the middle of December and the last of February (about ten weeks) there were 1,200 more deaths from respiratory diseases than for the same weeks during the past quinquennium. There were 800 more deaths from diseases of the heart, kidney, and bloodvessels during these ten weeks than for the past quinquennium in the same period. The department of health undertook a vigorous campaign of enforcement and education, arresting 1,500 spitters in one week in the beginning of January, and distributing leaflets and providing press bulletins during the beginning and height of the epidemic. He could find no basis for popular and medical belief that the epidemic was due to the influenza bacillus.

Complications and Sequelæ of Grippe in the Nose and Throat with Suggestions for Preventive Treatment.—This paper, by Dr. William Ledlie Culbert, of New York, appears on page 1182 of this issue of the Journal.

Aural Complications of Grippe.—This paper, by Dr. Edward Bradford Dench, of New York, appears on page 1180 of this issue of the Journal.

Dr. Edward E. Cornwall, of New York, cited from the Journal of Governor John Winthrop of Massachusetts, under date of 1647, a reference to what was apparently an epidemic of influenza which swept over New England at that time. Winthrop, in speaking of the treatment in vogue during that epidemic, commented to the effect, that of the patients who were treated by the regular physicians with bleedings and purgings, many died, while of

those who were treated by the old women with cordials and comforting things, none died. Doctor Cornwall thought that the essential thing in the treatment of grippe was suggested by this ancient observation, viz., absolute rest in bed and supportive measures, with avoidance of those things which tended to weaken the organism in its fight with the disease; and he considered it a fair question, whether the widespread and extravagant use of the coal tar preparations and their chemical congeners in the treatment of grippe during the past generation had not contributed extensively to the great mortality which was traceable secondarily, at least, to the grippe. He thought it interesting to note that the great increase in deaths from diseases of the heart and cardiovascular system observed in recent years occurred in just that period during which the medical profession had been led astray by the business enterprise of the managers of the German dye factories, who had discovered how easy it was to make the doctors use their coal tar waste products as medicines, notwithstanding the fact that they were protoplasmic poisons, and especially myocardial degenerators. While other factors, no doubt, took part in the increase of deaths from cardiovascular diseases noted during the past generation, he thought it not unreasonable to give some of the credit to the very general and extravagant use of the coal tar drugs and their like.

The speaker had been much interested in Doctor Dwyer's reference to the parallel between influenza and diphtheria. He had alluded to the same thing in a paper read six years ago, and had there mentioned the similarity in the invasions of the mucous membranes, in the neuralgic pains, in the prostration, and in the myocardial depression and degeneration. He was also glad to know that Doctor Dwyer had a rational ground for objecting to the use of vaccines in influenza.

He reported an unusual type of complication of influenza which he had observed only in 1915, and in five cases. This complication was characterized by a sensation of heaviness, and loss of power in the lower extremities, and in the severer cases it rendered the patient absolutely bedridden. The worst case which he had seen occurred in a woman of about sixty years, who had had the grippe to his own knowledge from one to four times a year for the past fifteen years or thereabouts. This woman was confined to her bed with a practically complete paralysis of both legs for five months, after which she always made a gradual but complete recovery.

Dr. Joseph Friedman said that a number of young adults who had a persistent cough following an attack of grippe were referred to him for röntgenographic examination to ascertain if there were any tuberculous lesions. Stereoröntgenographs of the chest showed no evidence of tuberculous involvement, but a marked thickening and beading of the vertebral branch of the bronchi and their anterior and posterior branches, suggesting chronic bronchitis.

Dr. Paul Luttinger said that it might not be amiss to draw attention to a disease which showed great similarity to influenza in its mode of infection, and the etiology of which was ascribed to an organism belonging to the same hemoglobinophilic group of bacteria as the influenza bacillus, namely, whooping cough. The number of deaths from pertussis amounted to 385 in 1915, a high figure for New York. In reference to its epidemiology, they had been doing some research work in the laboratory, and some of the results might be of value in this discussion. They had been studying whooping cough, and came upon a good way of spreading the infection, not only of whooping cough, but of any respiratory disease. It was found that in the cheaper moving picture shows, in the tenement districts of the Bronx, Harlem, and Brooklyn, children would be admitted with a paroxysmal cough and would be sitting on the benches side by side with healthy children. An attendant would then come along with a perfume atomizer to "refresh the air," and as the children coughed, the atomizer very effectively spread the bacilli all around. Many of the children doubtless had influenza which had probably been contracted in the moving picture places. The cars also were frequently responsible for the spreading of disease. He then cited an instance where a woman boarded an elevated train at 105th Street and sat with her two children opposite to three children who had whooping cough. When she sat down she did not know they had the cough, for they looked perfectly normal, but a few stations further downtown they began to whoop. The mother of the three children could not attend to all of them at once, and on account of the crowded car the healthy children could not leave the car. The result was that a few weeks later the two children came down with the disease. It would seem that some regulation by which persons with coughs and colds might be excluded from public places and conveyances and thus prevent the "bad" men, as Doctor Wilson called those who lacked resistance, from getting the infection.

Doctor Myles said that his observation this winter with his clientele was that he had never had such favorable results; he could not say whether this was due to the treatment or to Nature. In his opinion, the epidemic started in San Francisco and came east gradually. In his opinion, the epidemics were spread by the congregation of people in large buildings with closed windows and revolving doors. He had never seen a severe epidemic in summer when the doors were all open. Ventilation along proper lines, however, was expensive.

He then told of a committee of which he was a member, which had once tried to secure proper ventilation in public buildings, theatres, etc., but could not accomplish much for they were told that it was too expensive to install and use the proper apparatus. The best time to treat influenza was during the incipient stage, but specialists and physicians more often had to treat the consequences or sequelæ. Doctor Myles knew of nothing better than using some volatilized oil in steam; it reached all the mucosa in the respiratory tract. He felt, also, that he had obtained good results from injection of an argyrol solution into the trachea and bronchi. He had also had some experience with ear cases, and in nearly every instance where the drum membrane was incised, the patient recovered quickly. Several of his patients had hemorrhagic conditions.

Letters to the Editors

"INFLUENZAL" POLIOMYELITIS.

CARMEL, N. Y., *December* 4, 1916.

To the Editors:

The interesting article on epidemic gastroenteritis, etc., by Dr. Bernard Frankel, in this week's issue of the NEW YORK MEDICAL JOURNAL, goes far to corroborate my contention that infantile paralysis is a development of influenza. As he states, . . . "infantile paralysis has no clinical or etiological entity." This, I believe, should receive the endorsement of the entire medical profession. If such is the case, then it must be connected with some other disease.

The doctor states that . . . "it is a 'complication' of an infectious disease, that may or may not follow it." Why "complication"? I beg to respectfully take exception to this use of the word complication and desire to substitute instead the word "extension," or "development," and to attribue to influenza, the prevailing epidemic disease, the parentage of this interesting offspring. It is decidedly erroneous to regard it as a complication of any disease, just as it would be erroneous to consider, e. g., tuberculous meningitis, as a complication of tuberculosis, or syphilitic osteomyelitis as a complication of syphilis. Just as these two phases of disease cited are extensions of tuberculosis and syphilis, respectively, so is poliomyelitis an extension of influenza.

It is an "extension" to the spinal cord and its membranes of the very same influenzal process, that gives us "influenzal coryza," "influenzal bronchitis," "influenzal laryngitis," "influenzal gastritis," etc. It is but a very short step from any one of these to "influenzal poliomyelitis," and this is the correct term to use in identifying or placing the so called mysterious disease.

To the amazing lack of appreciation by the medical profession of the true nature of influenza as a constitutional disease, and its right to rank side by side with such constitutional diseases as syphilis and tuberculosis, having, like them, similar ramifications and extensions throughout the body, is due the fact that many of its peculiar forms and developments are mistaken for distinct, separate diseases, whereas, in reality, they are part and parcel of the basic influenzal process, as I have repeatedly pointed out.

What has been said above regarding poliomyelitis holds good also for the epidemic gastroenteritis to which Doctor Frankel calls attention. The correct term to use in referring to it is "influenzal gastroenteritis."

JOSEPH D. HARRIGAN, M. D.

Book Reviews

[*We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.*]

A Laboratory Manual of Organic Chemistry for Medical Students. By MATTHEW STEEL, Ph.D., Professor of Organic and Biological Chemistry, The Long Island College Hospital, Brooklyn, New York. First Edition. First Thousand. New York: John Wiley & Sons, Inc. London: Chapman & Hall, Limited. 1916. Pp. viii-193.

The avowed purpose of this volume is to provide a laboratory manual of experiments in organic chemistry of sufficient breadth to give the medical student a proper preparation for the understanding of the recent advances made in the subject of biological chemistry. At the same time it has been the author's desire to do away with the greater part of the unessential material connected with the subject of organic chemistry in general so as not to overburden the medical student. We feel that both of these purposes have been fulfilled in a very creditable manner, leaving little to be desired in the direction of additions or deletions. The volume is one of detailed experimental directions only, but the author has done well to interject occasional explanatory notes and to include suggestive questions regarding the several experiments in order to set the student thinking and therefore to enhance his understanding of the nature of the chemical changes taking place under his eyes. One particularly good feature of the experiments, as given, is their accurate quantitative nature. In each case the precise amounts of the substances to be used are specified. This makes for greater success in the experiment itself and serves to eliminate the large factor of waste so often associated with courses in experimental chemistry. There are very few errors in the book, and those are of minor nature. As an example, might be cited the mention of the tests for digitalin. This is a loose expression rather than an actual error, but it mars the book slightly. The term "digitalin," used without modification, is vague and may mean any one of a number of different substances. Nevertheless the author uses it to mean a single glucoside. Does he mean the true digitalin of Kiliani, digitaline of the French (digitoxin), or the variable mixture of glucosides known as German digitalin? Altogether, however, the book should prove a valuable and serviceable laboratory manual for teachers as well as students.

The Practitioner's Visiting List, 1917. Thirty Patients per Week. Philadelphia and New York: Lea & Febiger, 1916. Pp. 191. (Price, $1.25.)

This pocket visiting list of 200 pages is beautifully bound in leather with flap pocket, etc. It is adapted for thirty patients weekly and can also be obtained in three other styles: monthly, undated, for 120 patients a month; perpetual, undated, for thirty patients weekly a year, and sixty patients, undated, for sixty patients weekly a year. Several pages are devoted to general memoranda, obstetric engagements and practice, vaccinations, death register, addresses of patients, and cash account. In addition it contains calendars for 1917 and 1918, notes on uranalysis, incompatibilities, artificial respiration, and a host of other interesting and practical topics.

Interclinical Notes

A lady residing in Wayne county, Ohio, states that she has read in the JOURNAL that there is no cure for hay fever. We feel pretty certain that we have not published any such categorical statement. Our correspondent continues, however, that after suffering from hay fever for many years she discovered a remedy. The victim must begin in early summer by drinking a strong infusion of strawberry leaves mixed with pink clover blossoms instead of plain water whenever thirst is to be slaked. When the pollination season begins, an ointment is used inside the nose, over it, and around the temples; this ointment is composed of equal parts of turpentine, lard, and "common liquid washing ammonia." Our sympathy with hay fever sufferers is such that we offer no apology for publishing this unorthodox prescription, although we think some caution is necessary in using the ointment on a mucous membrane.

* * *

Of papers likely to be of special interest to the practitioner in the *Scientific Monthly* for December, we may cite The Strategics of Scientific Investigation, by Professor T. Brailsford Robertson; The Desire for Food in Man, by Minna C. Denton; The Psychology of War, by Dr. D. E. Phillips; Our Duty to the Future, by Professor C. E. Vail; and the Origin and Evolution of Life on the Earth, by Dr. Henry Fairfield Osborn. We have read this magazine since boyhood's days, and we were delighted to find in conversing the other day with a distinguished specialist that he, too, had been an admirer for over thirty years. We hope our readers will accept our conjoined opinion that it is eminently fitted for the practitioner's leisure hour, telling in most agreeable fashion what is agitating the minds of his fellow scientists.

* * *

The English of the *Scientific Monthly* is usually admirable. Why, let us ask, however, does Minna C. Denton word a sentence in this singular fashion?: "The author does not wish to be understood as making the claim that these diseases . . . always or often have overeating as a sole or chief cause." Our own contributors are so fond of using that word "claim" when they mean "statement" that we have learned to know what they are driving at; but

why should this lady deny that she demands the right and title to a statement concerning the sad consequences of overeating?

* * *

Leslie's for December 7th, speaks as follows concerning a certain kind of fool legislation: "Fads! Food fads and needless waste are responsible for a good part of the increased cost of living. The rise in flour to prices unexampled in this generation comes at a time when we have a law that foolishly forbids millers to blend a small portion of flour made from corn with flour made from wheat. This would make flour cheaper and add to its nutritive value, yet the law forbids it, just as it forbids the manufacture of oleomargarine even when made of the most wholesome materials, unless it pays a high tax which, of course, is a burden upon the consumer. An edible and very digestible butter is now being made in part from the oil of coccanuts and we presume that this will, also, be taxed to death at the behest of the butter makers. Drastic cold storage regulations have interfered seriously with the storage of food products in times when they are plentiful for times when they are scarce, and this has added to the cost of living. Pure food laws are needed, but when we carry them to ridiculous extremes somebody must foot the bill and that somebody is always the dear, long suffering, patient, shoulder bent public."

Meetings of Local Medical Societies

MONDAY, *December 18th.*—New York Academy of Medicine (Section in Ophthalmology); Psychiatric Society of Ward's Island; Medical Association of the Greater City of New York; Medical Society of the County of Erie (annual); Elmira Clinical Society (annual).

TUESDAY, *December 19th.*—New York Academy of Medicine (Section in Medicine); Federation of Medical Economic Leagues of New York; Medical Society of the County of Kings (annual); Tri-Professional Medical Society of New York; Tompkins County Medical Society (annual); Medical Society of the County of Monroe (annual); Binghamton Academy of Medicine; Syracuse Academy of Medicine (annual); Ogdensburg Medical Association; Oswego Academy of Medicine.

WEDNESDAY, *December 20th.*—New York Academy of Medicine (Section in Genitourinary Diseases); Alumni Association of the City Hospital; Schenectady Academy of Medicine; Medicolegal Society (annual); Buffalo Medical Club; Northwestern Medical and Surgical Society of New York (annual); Bronx County Medical Society; Dunkirk and Fredonia Medical Society (annual); Buffalo Academy of Medicine.

THURSDAY, *December 21st.*—New York Academy of Medicine (stated meeting); New York Celtic Medical Society; German Medical Society, Brooklyn; Auburn City Medical Society; Geneva Medical Society; Aesculapian Club of Buffalo.

FRIDAY, *December 22nd.*—Society of German Physicians, New York; New York Clinical Society; Manhattan Medical Society; Brooklyn Society of Internal Medicine (annual); Italian Medical Society of New York.

SATURDAY, *December 23rd.*—New York Medical and Surgical Society; West End Medical Society; Lenox Medical and Surgical Society.

Official News

United States Public Health Service:

Official list of changes in the stations and duties of commissioned and other officers of the United States Public Health Service for the seven days ending December 6, 1916:

BOGGESS, JOHN S., Surgeon. Relieved from further duty at Seattle, Wash.

BROWN, B. W., Surgeon. Relieved from further duty in connection with the Southern Sociological Congress and directed to rejoin station at Boston, Mass.

DERIVAUX, R. C., Assistant Surgeon. Directed to proceed to New York City for conference with the International Health Board in regard to plans for malaria work during the next year.

FULLER, J. K., Assistant Surgeon. Relieved from duty in plague eradicative measures in San Francisco and directed to report to the commanding officer of the Coast Guard cutter *Manning* at Astoria.

LIDDELL, T. J., Assistant Surgeon. Directed to take temporary charge of the Marine Hospital at Mobile, Ala., during the absence of Surgeon J. T. Burkhalter, on leave.

SIMPSON, Friench, Passed Assistant Surgeon. Directed to proceed to Vinton, Iowa, to investigate a reported case of bubonic plague.

STIMSON, A. M., Surgeon. Directed to proceed to Rochester, Minn., for duty in connection with investigations of poliomyelitis.

THOMPSON, L. R., Passed Assistant Surgeon. Detailed to attend the annual conference of health officers at Louisville, Ky., December 13, 14 and 15.

TRASK, J. W., Assistant Surgeon General. Directed to proceed to Louisville, Ky., to attend a conference of health officers, December 13, 14 and 15; also to represent the service at a conference with the Kentucky Commission on Provision for the Feebleminded.

WARREN, B. S., Surgeon. Detailed to attend the conference held at the U. S. Department of Labor, Washington, D. C., December 5 to 9, and participate in the discussions on health insurance.

WOODS, B. O., Assistant Surgeon. Directed, while in Alaskan waters, to make a sanitary survey of the city of Juneau.

Births, Marriages, and Deaths

Died.

BEIL.—In New York, on Thursday, November 30th, Dr. Charles Louis Beil, aged forty years.

BESEMER.—In Ithaca, N. Y., on Sunday, December 3rd, Dr. Martin Besemer, aged sixty-nine years.

COLEMAN.—In Asbury Park, N. J., on Wednesday, November 27th, Dr. Frederick Frelinghuysen Coleman.

COLGAN.—In Bridgeport, Conn., on Friday, December 1st, Dr. Walter John Colgan, aged twenty-five years.

CRIGHTON.—In East Hartford, Conn., on Tuesday, November 28th, Dr. Andrew John Crighton, aged fifty-two years.

FOREMAN.—In Kane, Ill., on Monday, November 27th, Dr. Claude Bernard Foreman, aged forty years.

GOMBEL.—In Baltimore, Md., on Wednesday, November 29th, Dr. William G. Gombel, aged sixty-two years.

HOGSETT.—In Saratoga Springs, N. Y., on Sunday, November 26th, Dr. Charles Young Hogsett, of Fort Worth, Texas, aged forty-four years.

LORD.—In Rochester, N. Y., on Tuesday, November 28th, Dr. Matthias L. Lord, aged seventy-seven years.

LOWE.—In Canaan, Maine, on Sunday, November 26th, Dr. Ivory Lowe, aged eighty years.

MONTGOMERY.—In North Birmingham, Ala., on Monday, November 27th, Dr. Edwin R. Montgomery, of Louisville, Ky., aged sixty-nine years.

MUNSEY.—In Suncook, N. H., on Sunday, November 26th, Dr. George F. Munsey, aged sixty-one years.

NORMAN.—In Millerstown, Ohio, on Thursday, November 23rd, Dr. L. Monroe Norman, aged sixty years.

ODELL.—In Detroit, Mich., on Monday, November 27th, Dr. Robert W. Odell, aged seventy-five years.

REED.—In Philadelphia, on Friday, November 29th, Dr. George Kempton Reed, aged sixty-nine years.

ROACH.—In Quaker Street, N. Y., on Saturday, December 2nd, Dr. Paul Roach, aged sixty-seven years.

ROBINSON.—In Amesbury, Mass., on Tuesday, November 28th, Dr. Harry Pringle Robinson, aged forty-one years.

SIEBER—In Chicago, on Thursday, November 23rd, Dr. Francis Adam Sieber, aged seventy-five years.

SINCLAIR.—In Grand Rapids, Mich., on Sunday, November 26th, Dr. Malcolm C. Sinclair, aged sixty-six years.

TAYLOR.—In Edinboro, Pa., on Sunday, November 19th, Dr. Isaac M. Taylor, aged seventy-eight years.

TODD.—In San Francisco, Col., on Monday, November 20th, Dr. David Byron Todd, aged sixty-nine years.

WALLING.—In Chicago, Ill., on Tuesday, November 28th, Dr. Willoughby Walling, aged sixty-seven years.

THE PRESENT MANAGEMENT OF THE POLIOMYELITIS EPIDEMIC IN NEW YORK CITY.*

BY FREDERICK TILNEY, M. D.,
New York,
Department of Neurology, Columbia University.

AND JAQUES C. RUSHMORE, M. D.,
New York,
Department of Orthopedics, Long Island College Hospital.

In spite of the fact that we have had three epidemics of poliomyelitis in the past nine years, we were not prepared for the last one. We were not prepared with substantial ideas concerning a quarantine calculated to safeguard the community. Alarms caused terror and panic until at length the quarantine became a travesty because of its inconsistencies or system of détours defeating the purpose of safety. We were not prepared for the hospitalization of the large number of children stricken by the disease. We had no broadly conceived plan for the proper clinical management of these patients. We had taken no particular thought as to how the best interests of these children might be served in their hospital care. Nothing seemed further from our minds than the recognition of the great opportunity for clinical study, of the unparalleled chance to advance our knowledge of this disease, and of the abundant clinical material from which to accumulate data invaluable to the diagnosis, prognosis, and treatment of the disease. There were many workers who devoted themselves arduously and earnestly to their task. It was not their fault that the hospitals were undermanned and the staffs sorely overworked. It was the lack of intelligent organization, the lack of well conceived planning, which caused the hospital situation to struggle along as best it could, perhaps to the detriment of the patients, certainly to the disadvantage of medical science. In its acute stage, therefore, this epidemic, like many others before it, must pass into medical history without sufficient scientific record.

In the matter of treatment for the acute stage we were found unprepared. We fluctuated between conservative expediency and radical experimentation. Those who advocated adrenaline injections met the criticism that rest and quiet were safer. The adherents of immune serum were soon to hear that horse serum was quite as efficient. Fortunately, the purely experimental use of diphtheria antitoxin was limited and shortlived because of its disastrous results. We were unprepared in forethought for the aftertreatment of the disease. No concerted effort was made to devise ways and means effectually to organize the forces necessary to this treatment. The patients were recommended to attend certain clinics or dispensaries and there the matter ended. This is a serious and important consideration. We owe to these little children the best care we can give. They are entitled to every effort in treatment which will reduce their handicap to a minimum as they are starting out in life. We owe it to ourselves to acquire the knowledge as to which are the best means of treatment for the paralysis, so that we may be of greater service to the children stricken this year, and also that our conclusions shall be useful in future epidemics.

Are we now doing the best that may be done under the circumstances? Perhaps, but there is room for improvement. In order to make a comprehensive answer to this question it will be necessary to consider, first, the adequacy of the method of aftertreatment in force and, second, the efficiency of such measures as are now employed.

The figures presented here are based on a study of the conditions obtaining in ten of the largest institutions in this city at present caring for about three thousand cases. The fallibility of such statistics is always admitted, but they offer the most graphic means of analyzing the situation.

Any method of aftercare, to be adequate, would require much calculation and thought. Such a method must have established a plan which would afford the best attention that may be given to these patients. This plan should determine which of the several departments of medicine concerned with the disease should have the direction of the cases; also what departments would form the most advantageous combination in furnishing the elements necessary to successful aftercare. A carefully considered plan would likewise have devised a classification for the grouping of cases. The residual defects of poliomyelitis differ in kind as well as in d
The patients, therefore, should not be turn

*Read before the New York Neurological Society at the New York Academy of Medicine November 14, 1916.

discriminately into a clinic, but should be individualized with reference to the needs of their aftercare.

In addition to these important features, there should be included a system of regular reexaminations at stated intervals, from which valuable statistics concerning the results obtained from the treatment might be compiled. Means should be provided for keeping a careful record of these findings in each case.

A system of distribution of the cases, according to the districts from which they come as well as the institutions most accessible to them, would facilitate the work. Arrangements should be made for the home treatment of such patients as may be unable to attend clinics. The requirements of

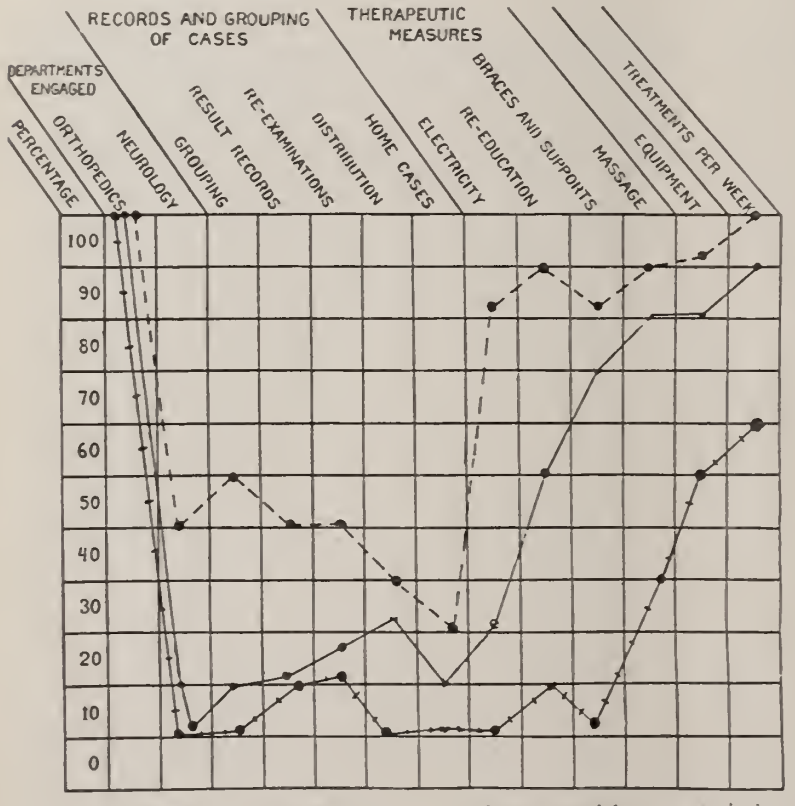

Fig.—Best work, - - -; average mean, ——; and most unsatisfactory, —|—|—|—.

equipment, as well as the therapeutic measures calculated to give the best results should be included in the details of any plan capable of producing an adequate method for the aftercare.

According to the method in force at present, all cases are placed in charge of the Department of Orthopedics, although only thirty per cent. of the patients under observation are receiving distinctly orthopedic treatment. In the matter of cooperation between departments, there is a marked deficiency. In few instances has the neurological department been given any thing like a coordinate position in the care of these cases. It seems hardly necessary to dwell upon the fact that poliomyelitis, both in its acute stage and during the stage of paralysis, is a disease of the nervous system. To those recognizing this fact it is obvious that the knowledge and experience of the neurologist cannot fail to be of value in the aftertreatment. The adequacy of method, therefore, falls at present far below what might be desired in this important detail of cooperation between departments.

In the majority of instances, as the cases enter the clinics, no attempt is made to classify them with reference to their therapeutic needs. Sixty-four per cent. of the children in this epidemic were under five years of age. Muscle reeducation is impracticable in children under three and a half years, because it is impossible to obtain their voluntary cooperation. Children from three and a half to five years of age may derive much benefit from reeducation. They form a group difficult to instruct and should be delegated to the most experienced teachers. Children of five years and over need less specialized attention. Here, therefore, are three groups with reference to muscular training which should be recognized at once and dealt with accordingly.

A certain small percentage of cases requires measures to correct deformities before any other treatment is undertaken. This number should be negligible if the acute stage is properly managed. Many cases need neither support nor correction, but require massage, electricity, and training. In another relatively large group, support to prevent muscle stretching and joint injury is indicated in addition to the measures just mentioned. Not a small group is that in which electricity is inadvisable. Especially is this true in young infants to whom the currents are excessively irritating. Another group comprises cases characterized by pain, tenderness, and marked vasomotor relaxation. These cases show most improvement when treated by dry heat. All other means of treatment should be avoided until the pain and tenderness disappear. There is also the relatively small group in which the axial musculature alone has been affected. In this group corrective gymnastics are most effective.

It is desirable that a complete neurological examination and record be made in every case before treatment is undertaken. This may be most advantageously assigned to the neurologist, and the differentiation into groups made by him. At present, except in rare instances, this differentiation is not made, and the only apparent classification in many places is that determined by a passion for plaster of Paris and braces, or a disregard for electricity. In the matter of regular reexamination of cases and statistics showing the results of treatment, the present management is particularly deficient. This is to be regretted, as it deprives us of information valuable for future use.

The distribution of the cases for treatment according to their districts has either been overlooked or not yet sufficiently organized to be of any value. There is no reason why a Brooklyn case should be treated in New York or why a New York case

should go to Brooklyn which, strange as it may seem, is of not infrequent occurrence. Such a distribution of cases by districts would spare many children unnecessary fatigue, and be at the same time less wasteful of the parents' time and efforts. It would also do away with the well known drifting about of patients from clinic to clinic and prove an actual economy, particularly in the matter of braces.

In general the equipment, including floor space, arrangements, and accommodations is good. There is, with one notable exception, a considerable deficiency in the more improved accessories for muscular training as well as electrical apparatus. That the therapeutic measures employed in the several institutions are not subject to any marked uniformity may be noted at a glance. Some of this is explained by complaisant prejudice, some is due to enthusiasm in pursuit of so called new ideas. For example, electricity as a therapeutic measure is in many places dismissed as worthless. Of course, we have no doubt that this attitude is directed against the improper and inefficient use of electricity. Knowing the source from which the objection comes, we feel certain that its sponsors have no intention of gainsaying a general biological law which they understand as well as we do, the law holding that highly differentiated tissues, when deprived of the opportunity to perform their natural functions, tend to revert to the primitive embryonic type of tissue whence they took their origin. Muscle is among the most highly differentiated of tissues; prevented from performing its natural function of contraction, it tends to revert to mesenchyme, the noncontractile connective tissue type. A flaccid, paralyzed muscle has lost its connection with the centre which energizes it to contraction. It does not contract voluntarily or reflexly. Eventually, in the course of weeks or months, it may regain the lost connection with its centre of energy. During all this time it is manifesting a tendency to go back to mesenchyme. It remains for us to supply the deficient function of contraction by whatever means we possess. Electricity is one of these means. Massage and passive movements are other means. If we neglect them the nerve may regenerate but find, when it comes to innervate its muscle again, a mass of completely or partially incontractile tissue.

The electricity to assist in this work cannot be had from a one cell buzzer battery, nor by throwing in the switch of the wall plate and simply letting the current flow. It is not only a particular type of current that is needed, but it must be properly applied and its use carefully supervised. The sinusoidal galvanic current is now regarded as best adapted to produce the necessary contraction. It has the advantages of a slow wave current, gradually increasing from minimum to maximum strength and alternating in polarity. It causes little or no discomfort, for which reason children can tolerate much more electricity this way than they can by the sudden make and break of the ordinary interrupted galvanic. Ten to fifteen milliampères is a sufficient dose. This amount may be slightly increased, if necessary, but usually no increase is needed. The duration of application in early cases should not exceed five minutes. A shorter interval is advised if the muscles stimulated give evidence of fatigue by showing lessening contraction. Cases of long standing may be treated for ten or fifteen minutes. Equally important is the method of application. Before beginning electric treatment it is desirable that the affected parts be massaged and then warmed by a calorescent lamp or hot pack. This procedure makes it possible to obtain good muscular contractions with much less current than would otherwise be required. The electrodes should be stabile. A towel wrung out in warm water is wrapped about the part to be stimulated. Over this the electrode is placed and held in position by bandage or tape. Sheet lead cut to the desired size and shape makes an excellent electrode and may be moulded to the part treated. Care should be taken to prevent the metal from touching the bare skin. This kind of electricity properly applied and under proper medical supervision, is beneficial and efficient in producing muscular contraction. Electricity in this sense is one of the essential factors entering into the combination of therapeutic measures requisite to the most effectual treatment during the stage of paralysis.

The electric current is also a valuable agent in the diagnosis and prognosis of the disease. It is the most reliable guide in directing the treatment, since it definitely points out the relative degrees of paralysis in the affected muscles, thus indicating the groups to which most attention should be given. Its value as a diagnostic measure has long been known to neurologists; they better than others understand its application and significance. In this fact is an added reason why the responsibilities assigned to neurology should be dominant in the diagnosis and treatment of poliomyelitis.

Muscle reeducation, to be most efficient, requires an elaborate system of accessories and a well trained staff of instructors. With one conspicuous exception, no such efficiency has yet been attained. This exception, however, is so noteworthy that it may well serve as a model for us all, in fact, it is a question whether better work in this line is being done anywhere else in the world today. Unfortunately, the inadequacies in muscle training in most institutions are such that in spite of this single particular excellence, the general average is low. To depend entirely upon muscle education, however, to the exclusion of electricity and massage, to allow a muscle to degenerate through failure to use these latter measures, and to rely upon an impulse from the central nervous system to maintain the nutrition of a muscle through nerve fibres which we know to be defective, cannot be too strongly condemned.

By and large the use of strictly orthopedic measures has been wise and conservative. On the other hand, in certain institutions caring for large numbers of children, some form of rigid support is insisted upon in nearly every case, on the average only one case in ten escaping this routine treatment. This attitude is extreme. As disuse results in atrophy, and as the maintenance of a well developed muscle is primarily essential for the regen-

erated nerve if function is to be restored, methods of fixations in the early stage should be used only to correct existing deformities. Equally harmful is too hasty prescribing of braces to encourage locomotion when rest is the imperative indication. A weakened muscle may be damaged as much by overuse as by fixation of the parts. All muscle exercises should be done under careful supervision, and caution should be taken not to subject weak muscles to the stress and strain of weight bearing. Those who think of motility in terms of plaster of Paris and braces only have, to say the least, a splinted conception of human motion. Such treatment in vogue in a few places deflects the curve to a lower level than should be the case.

Massage has the distinction of almost universal approval and is, in general, well managed. The principles governing the application of massage, as in the case of electricity, are primarily anatomical. Overstimulation by any means of the antagonists of a paralyzed group serves only to further embarrass the defective muscles. To be most effectual massage should in all cases be combined with passive and resistance movements. This latter detail requires skilled and trained workers. Student masseuses should be under most careful supervision. Untrained rubbers should not be employed under any conditions. Parents certainly must be classified in this last group. Much damage may be done by inexperienced workers in the improper anatomical application of massage. There is a tendency at present to press into service hastily trained workers with insufficient anatomical knowledge (to say nothing of their ignorance of the art of massage), and to assign this work to parents with no further instruction than to "rub the baby's leg every day."

From the statistics obtained, the accompanying chart was constructed, the curves of which show in graphic manner the character of the method for treatment now in force.

The curves charted were determined by a study of conditions in the several institutions, allowing 33.33 per cent. each upon the following counts:

1. Comprehensiveness of plan for treatment adopted.
2. Thoroughness of organization.
3. Effectiveness of work.

Three curves are shown, representing respectively the best work that is being done, that which seems the most unsatisfactory in the details mentioned, and a more or less indefinite mean between these extremes.

One of the most prominent defects is seen in the lack of cooperation between the departments of neurology and orthopedics. This combination at its best is only forty per cent., and as this figure is attained in but a single institution it does but little to sustain the general average in this important element of organization; this average being only six per cent. of efficiency.

In one institution the effort at grouping the cases with reference to their therapeutic needs represents fifty per cent. of full efficiency, while in the remaining clinics and dispensaries engaged in the work so little has been attempted in this direction as to render the general average less than ten per cent.

Adequacy in recording cases which may serve as the basis of valuable statistics is at its highest only forty per cent. It is so generally low as to bring the average down to less than fifteen per cent. These figures also apply to the reexamination of cases.

The average attained in distribution of the cases according to their districts is five per cent. Provision for the care of home cases or for cases which cannot be brought to clinics and are being treated in hospitals is valued at nine per cent. of full efficiency.

Electricity where best used and supervised is rated at ninety per cent., but its general application in the aftercare is so indifferent as to bring the general average down to ten per cent.

Despite the fact that one institution is entirely worthy of being rated at full efficiency in the matter of muscle reeducation, the general effectiveness of this treatment is so low as to force the average down to sixteen per cent. Were it not for the fact that the excessive use of supports was so prominent in a few institutions, this feature of the treatment would maintain a high average. Even with the handicaps placed upon this part of the treatment by the few clinics which make plaster of Paris and braces a routine formula, the average is seventy-five per cent. The general average for massage and equipment is also about seventy-five per cent.

Concerning the efficiency of such means as are employed, certain details are worthy of note. Owing to the lack of proper distribution of patients by districts, many of the clinics are overcrowded and overworked, while others are not up to their capacity. This not only handicaps the efforts of the workers, but detracts from the value of the treatment and requires an unduly long wait in the clinic for the majority of patients. This waiting is not only wasteful of the parents' time, but tends to discourage them in the continuance of the prolonged period of treatment necessary in the majority of cases. The proportionate relation between attending physicians and patients is eighty per cent., between graduate nurses and patients sixty-one per cent, between masseuses and patients sixty per cent., and between instructors in muscle reeducation and patients only twenty-five per cent.

These statistics show that with certain marked deficiencies in places we are doing fairly well in what we have attempted to do.

Where we fall short is in the method and plan of treatment. Here we manifest confusion of ideas and lack of deliberation. Without taking any unnecessary thought in the matter we have been willing to proceed along the lines that seemed to have sufficed in previous epidemics. The results are not surprising and we can see that there is much room for improvement.

CONCLUSIONS.

What we are most in need of at present is a comprehensive plan of organization. The sugges-

tion here offered aims at the formulation of a method which will obviate many of the present deficiencies as shown by the statistics. The proposed plan covers the following details:

1. The management of the aftercare should be assigned to the department of neurology, since the problems of the vast majority of the cases in diagnosis and classification, in recording and prescribing, belong most properly in this field.

2. The ideal combination of departments in the aftertreatment will come from the intimate coordination of neurology and orthopedics.

3. Before treatment is prescribed the cases should be classified and grouped according to their therapeutic needs. This is the province of the neurologist.

4. Reexaminations of all cases, together with careful records of the findings, should be made at stated intervals, not only in the interest of changing or modifying the treatment as circumstances demand, but also for the information to be gained as to relative values of the several methods of treatment.

5. A distribution of the patients upon the basis of their districts of residence and the institution most accessible to them should be made and adhered to as far as possible.

6. No one mode of treatment should be employed to the arbitrary exclusion of all others. Every therapeutic means having the sanction of authority should receive due consideration in deciding the therapeutic requirements of each case.

7. In order to render such organization most efficient, certain regulations should be adopted for the guidance of the several institutions engaged in the work. Some unit of staff organization must be decided upon, such for example as one physician to twenty patients, one masseuse, one instructor in muscle reeducation, and one electrotherapist to twelve patients, and one nurse to forty patients.

Regulations should also be made governing the number of patients treated in proportion to adequacy of equipment; also recommendations regarding the number of treatments a week for each patient, the home treatment by parents, follow up work by social service and means of transportation.

We may easily recognize that the development of anything like efficient organization requires broad, cooperative action, and that the need of such organization is pressing. In New York city alone there were over 9,000 cases of poliomyelitis this year. In the United States the number of those affected was over 26,000. This is a real menace to the population. The history of the disease shows that we may expect another epidemic sooner or later. When it does come again we cannot plead the emergency of the circumstances as an excuse for unreadiness. That excuse is worn thin already. There are a number of things we must know before the next epidemic arrives. We should acquire greater knowledge of the communicability of the disease, so that upon this knowledge we may devise a rational and reassuring quarantine. We must establish more certainly the criteria of diagnosis and plan more broadly for the clinical management of the disease during the acute stage. We must arrange for the most efficient study of the pa[illegible]an [illegible]e logical and serological material, and not leave these important matters so largely to chance. Above all we must arrive at definite conclusions concerning the best means of treatment to combat this affliction which, when it does not destroy, sets a blight upon so many victims.

If the statistics here given show a distinct lack of preparedness to meet this last epidemic, they also indicate a tendency to remain in this condition unless some determined effort is made in the near future. It seems not only wise but necessary, therefore, that we earnestly devote the proper attention to this matter against the time which is sure to come, so that we may be more confident in the advice we give, more certain in the means we employ, and, in our efforts, give evidence of concerted intelligence.

POINTS IN THE DIAGNOSIS AND TREATMENT OF POLIOMYELITIS.*

By B. Sachs, M. D.,
New York,
Neurologist, Mount Sinai Hospital; Alienist and Neurologist, Bellevue Hospital; etc.

The recent epidemic occurrence of poliomyelitis has induced the clinician, the pediatrist, and the orthopedic surgeon to become more closely acquainted with the disease; the neurologist, conscious, possibly, of his intimate knowledge of the subject, has refrained from stating publicly the results of a long experience with the disease and has not given account of the changes that have come over his own conception of infantile spinal paralysis. My readers must not expect an encyclopedic article on the subject of poliomyelitis; I have set myself the task of singling out for discussion a few points of special interest which may have some bearing on the proper early diagnosis and the treatment of the victims of this last epidemic.

We have a twofold duty toward the public: First, to assist, if possible, in the prevention of another epidemic, and, secondly, to lay down sensible rules for the guidance of the public in the matter of the selection of treatment.

As for the avoidance of future epidemics, the facts at our command show that the poliomyelitic virus is found in the secretion of the nose, mouth, and throat, and also, in some instances, in the gastrointestinal content; that for the present it may be positively identified only by the production of poliomyelitis in monkeys experimentally inoculated (1). The value of the discovery of the streptococcus isolated from the throats, tonsils, tonsillar abscesses, and the central nervous tissues, by Rosenow, Towne, and Wheeler (2), and corroborated by Nuzum and Herzog (3), will need further consideration. We know little about the exact manner in which the disease is carried from person to person. The facts to be considered are: The epidemic appeared in a very

*Part of a symposium on poliomyelitis at a joint meeting of the New York Neurological Society and of the Neurological Section of the New York Academy of Medicine, November 14, 1916.

rowded section of the city and spread most rapidly among the population of that section; before long it appeared in other parts of the city and in other parts of the State and country; the infection must have been spread by healthy carriers and also by intimate contact with those afflicted with the disease. It is more than probable that the contagion is most easily spread in the prodromal stage of the disease. It is of interest to know that in a number of instances several children in the same family have caught the disease evidently from one another, allowing for the probable incubation period (one to two weeks), but that in hospitals the disease has not spread as easily as it has in private dwellings. In the 1907 epidemic no child lying in the ward with children suffering from poliomyelitis contracted the disease, and I am not aware that any of the children sent to the special poliomyelitis wards and hospitals during the last epidemic (under mistaken diagnoses) have contracted the disease after the accepted incubation period. If the disease is spread by contact, it must be by most intimate contact, else we cannot explain why children in hospitals should be more exempt than those in the more crowded quarters of a small family. There is still considerable uncertainty, however, about the exact manner in which the infection is carried, and until further knowledge of the subject is obtained it will, of course, be well to advise immediate isolation and strict quarantining of the cases that occur, and we shall do well as medical men to urge the greatest possible cleanliness in the homes of the poor and rich, in the matter of the preparation of food, especially in the spring and summer months.

The better care of children's food during the past summer has led to a very remarkable decrease in the number of children dying from gastrointestinal infections, so that the entire mortality among children, according to the statement of the department of health, has not been greater than it was in nonepidemic years. If I had the authority to encroach still more upon the domain of the epidemiologist and of the health board physician, I would have the department of health insist upon covered garbage receptacles and would urge the proper screening of kitchens, markets, and hospitals. To the objection on the part of the health board that no one has proved that the virus is carried by insects, I would simply say that no one has disproved it: Let us make assurance doubly sure.[1]

Let me remind you that since the days of Heine (1840) the general symptoms of essential paralysis of children were known; the pathological anatomy of the disease was most carefully elaborated by the French and German observers in the seventh and eighth decades of the last century; that a little later Strümpell and Marie very strongly suspected the epidemic character of poilomyelitis and of some cases of polioencephalitis; that some of us who wrote textbooks many years ago, said of acute anterior poliomyelitis "that it comes on in the vast majority of cases after the fashion of an acute infectious disease"; that the first opportunity of studying a very extensive epidemic of the disease was by Medin, of Stockholm, in 1887, and that it was carefully described by his pupil, John Rissler, and that after there had been a very long discussion whether poliomyelitis was a parenchymatous or interstitial inflammation, it was shown to have been interstitial, and that the changes in the ganglion cells were secondary. But this seemed to be of minor importance once the evidence was established that the disease was, above all, an acute infectious disease of microbic origin. Most of us have long since forgotten the contention of Goldscheider, years ago, that poliomyelitis was often only a part of a general myelitis. We were well aware that the pathological findings of Charcot, Joffroy, and others were only the expression of the terminal stages of the disease whose initial stages were scarcely known. According to the studies of Wickman (5), Harbitz and Scheel (6), and the very comprehensive studies of I. Strauss (7), the pathological changes of the early stage of poliomyelitis include "a lymphatic infiltration of the anterior and posterior horns, and to a lesser degree also of the white matter"; other investigators dwell chiefly on edema, diffuse vivid injection of the bloodvessels, and punctiform or larger hemorrhages. So long ago as 1910, Strauss (*loco citato*) stated that "the presence in the white matter of edema coupled with . . . tigrolytic changes in the ganglion cells, offers a probable explanation of the rapid recovery of some of the paralyzed parts." Peabody, Draper, and Dochez (8) lay great stress on the edematous appearance of brain and cord, and conclude that the "damaging effects can be assumed to result in part from the direct pressure on the nerve cells of hemorrhages, edema, and exudate. Meltzer (9) has made clever use of these facts in formulating his plan of treatment, and very properly calls attention to the fact that all these conditions would during life be more pronounced than they appear to be when seen as post mortem findings. It is a fact especially worth noting that bulbar paralysis without anatomical findings plays a part in poliomyelitic infections as it does in certain chronic diseases of the adult.

Zappert's account of the epidemic in Vienna, in 1898, the excellent work of Wickman (5), the collective investigation report[2] of the epidemic in New York city in 1907 by your own committee, have familiarized the neurologist so thoroughly with the subject of poliomyelitis that he cannot share the general surprise which the disease has caused in the medical profession. What he has gained from the recent epidemic is the knowledge of the intense virulence of the disease, of the astounding rapidity of development, in some instances, and he has become more thoroughly acquainted with the atypical or unusual varieties of the disease. Incidentally be it said that every one of these atypical forms was recognized in the report of the Collective Investigation Committee of 1907 (published in 1911), and that the only difference between the epidemic of that year and the epidemic of 1916 is in the greater virulence and the higher mortality of the disease (26.24 per cent. in 1916). Since 1907 the work of Flexner, Landsteiner, and Popper (10), Lewis, Clark, No-

[1] At the meeting of the American Public Health Association held in Cincinnati, October 23d to 28th, the question of insects as carriers and of the contamination of food was thought worthy of discussion.

[2] The report is worthy of careful study; the chapter on treatment contains many useful hints. The report has been translated into foreign languages; New York authorities have forgotten it.

guchi, Netter (11), Roemer (12), Levaditi (13), and others, has brought us considerably nearer to the final recognition of the actual virus of the disease and to the possibilities of treating poliomyelitis by the intraspinal injection of an immune serum. We have also learned to appreciate the value of the cerebrospinal content as an aid to diagnosis, particularly in the early stages of the disease and in the doubtful cases occurring during an epidemic.

If we wish properly to understand the occurrence of the various types of the epidemic form of the disease, we must, of course, reconstruct any theory which would adhere too closely to the old time conception of an infection, singling out possibly the ganglion cells of the anterior horn and no other part of the central nervous system. Such a conception is, and always was wrong. As we view the disease now in the light thrown upon it by the recent epidemic, infantile spinal paralysis is a general infection exhibiting its power most markedly over the cerebrospinal axis. In its invasion of the central nervous system the meninges of the brain and the spinal cord, and especially of the cerebrospinal axis from the pons downward, may be involved and are involved in the furibund cases. In some of these the infection is evidently so intense that the respiratory and cardiac centres are seriously involved, and the patient may succumb to the disease within twenty-four or forty-eight hours. If the disease is less intense the meningeal involvement is noticeable only for the first few days, then subsides, and the effect of the poison is exhibited chiefly in the anterior gray matter of the cord. In other and less virulent cases the infection may be so slight that it produces merely the general symptoms of an acute infectious disease, a little headache, a little malaise, possibly a very slight rigidity of the neck, with vague pains throughout the system; but the infection is so slight that it affects the spinal cord to a very slight degree, if at all, and therefore never produces paralysis. We have, then, the furibund cases—often of the encephalitic type—the meningeal cases, the paralytic forms, and, lastly, the so called abortive cases, or, still better, the cases of infantile paralysis without paralysis. Viewed in this light, there does not seem to me to be much difficulty in establishing the various clinical types of the epidemic form of the disease.

We shall do well to retain the name of poliomyelitis, if for no other reason than that in a very large percentage of the cases the name accurately describes the chief lesion, and it is that lesion, with all its consequences, that gives us most concern. The bacteriologist and general clinicians will have to help us some day to combat the furibund forms and the meningeal cases.

For the proper treatment of the cases with paralysis, the neurologist will and always should be chiefly responsible. There is more to be said, however, regarding the early diagnosis of these various forms.

First, as to the furibund forms. During the period of an epidemic every man's guess has at least seventy-five per cent. probability in its favor. It will not be nearly so difficult, therefore, at such a time to recognize the furibund form of poliomyelitis as it would be at the very inception of an epidemic or in the interval between epidemics. The increase of the lymph cells and of the globulin content of the cerebrospinal fluid will corroborate materially the suspected diagnosis. It should not, however, be forgotten, and this will apply particularly to cases observed in nonepidemic periods, that there are forms of meningitis, including the tuberculous, occurring both in children and in adults, which may give entirely similar biological findings.[3] I am not sufficiently convinced as to the infallibility of laboratory methods and still less of the infallibility of the individual laboratory worker to yield to him wholly in the establishment of the diagnosis. Our board of health may have some justification in stating that the laboratory can be depended upon to make the differential diagnosis between meningitis and poliomyelitis at the time of an epidemic, but the experienced neurologist will surely look for other symptoms in substantiation of his diagnosis.[4]

The furibund forms which I have had opportunity of seeing, particularly in nonepidemic times, have always shown either an absolute diminution of all the deep reflexes, a marked loss of tonus in the muscles, a marked hypotonia, or in cases in which the meningeal symptoms preponderated, a slight increase of the reflexes and slight rigidity of the neck and spine; also a difference, determined by careful examination, in the paralysis of certain groups of muscles compared with others. A careful inspection of the entire body will, I am certain, in many instances reveal symptoms which can be used either to confirm or contradict the diagnosis. Purely clinical observation will be of great importance also in determining the exact condition of the muscular system in the cases of infantile spinal paralysis without paralysis. We must concede that there are such cases; but even in these a relative weakness of some groups of muscles can be demonstrated as well as a change of the deep reflexes, especially a diminution of the knee jerks, a loss of the Achilles reflex, and a loss of muscle tonus. It is in just such cases as these that a most detailed neurological examination, including electrodiagnostic examination, would be of the greatest value and interest.

As for the better known forms of poliomyelitic infection, those with more or less widespread paralysis, it is well to remember that whatever the laboratory findings may be, there are certain clinical features about poliomyelitis that are of the utmost importance. First of all, a rapidly developing paralysis, most intense at the beginning, occurs within twenty-four or forty-eight hours, and then subsides rapidly both as regards the number of groups of muscles involved and the intensity of involvement of each group; a very slight increase of the reflexes within the first day or two; after that a distinct diminution and a very early loss of the deep reflexes of the segments involved. Of almost equal importance is the behavior of the electrical reactions. During the first twenty-four or forty-eight hours the irritability is so great that an electrical examination can hardly be made. There may be a very slight increase of faradic irritability

[3] This view is shared by H. L. Abramson, of the health department, *Med. Record*, November 4, 1916.

[4] The importance of attaching young men with especial neurological training to the staff of health board inspectors is self evident.

during that period, but very soon we are bound to discover some form of partial or complete reaction of degeneration, except in cases of rapid recovery.

The difficulties encountered in the diagnosis of infantile spinal paralysis in children are not as great as is the recognition of the disease occurring in the adult, particularly during the time of an epidemic. Here again the experienced neurologist has, I believe, distinct advantage over others. Even he will not underrate the difficulties of the task. During the last month in my hospital service we have had a very marked example of an acute transverse myelitis in a man over forty years old, coming on with great suddenness, with a complete paralysis of the lower extermities and of the bladder, with absolute loss of sensation up to a definite level, and then subsiding just as rapidly and going on to complete recovery.

Several years ago I recorded similar instances of such cases as illustrating an acute infectious type of transverse myelitis. There is strong reason to believe, under the circumstances, that the poliomyelitic virus was responsible for the acute transverse myelitis observed this year. The laboratory findings were in support of this diagnosis.

During this same period we have had under observation an adult with a complete flaccid paralysis of both lower extremities, coming on suddenly, with a left facial paralysis, without marked changes in sensation, with some changes in the electrical reaction, without loss of bladder control, in whom we made the diagnosis of poliomyelitis. To our great surprise, the routine examination of the blood and of the spinal fluid showed a four plus Wassermann reaction, and the question then arose whether the original diagnosis was to be altered. One of our serologists naturally inclined to the view that this must be specific, and he might, perhaps, be encouraged in this view by the rapid improvement in the patient's condition, but I maintain that the mode of onset and the rapid subsidence of the symptoms were entirely in keeping with the diagnosis of a true poliomyelitis in a man suffering from constitutional lues. Considering the relatively great immunity the adult evinces toward this disease, it is of interest to put the question whether the preceding lues has possibly made this man more readily subject to this infectious disease.

At almost this same period I saw in consultation a lady in whom the diagnosis of poliomyelitis had been made because she had had some difficulty in the use of the right lower extremity, accompanied by distinct radiating pain of a rootlike character in that lower extremity without changes in electrical reaction and with marked increase of the deep reflexes in the affected leg. The onset was not accompanied by fever; it was slow and insidious in its development, and there was also slight tenderness on deep lateral pressure over the lumbar spines.

In this case the examination of the blood and of the cerebrospinal fluid yielded positive specific findings. I decided that the patient was not suffering from any poliomyelitic affection, but had spinal lues. Vigorous specific treatment brought about a rapid improvement in the patient's condition, the improvement being much more rapid than it was before this treatment was instituted.

It would be easy enough to increase such instances merely to prove that the entire subject of the diagnosis of poliomyelitis is one that requires, in many instances, the closest possible study on the part of men specially trained in the study of this disease, and that the neurologist, while he is only too happy to have the assistance of the bacteriologist, and in some instances also of the orthopedic surgeon, has to depend chiefly upon his own clinical insight and experience for the proper recognition of unusual types of the disease.

In the matter of treatment, also, I am of the opinion that there are several points which it is the duty of the neurologist to discuss and to put calmly before the general lay and medical public.

In the treatment of the furibund and meningeal forms, and, in fact, all the early forms of poliomyeiltis occurring during an epidemic, the neurologist will be only too ready to share honors and responsibilities with the pediatrist and general clinician. The early stages of the disease should be treated as would every form of a severe acute infectious disease. It is somewhat unfortunate that the American Public Health Association has said in its statement published in the lay press that "there is no specific treatment of established value in poliomyelitis." We medical men will understand the meaning of that word *specific,* but I hope the laity will not interpret it to mean that there is not much to be done at any stage of this disease. This same statement might apply to measles, or to scarlet fever, and surely no one would wish the public to believe that there is little for the physician to do in the earliest stages of either one of these diseases. It is my own impression that there are few diseases that would benefit so largely by discriminate and intelligent medical treatment as will these early and severe forms of poliomyelitis.

The treatment of the febrile condition, the method of feeding to be employed in cases in which there are apt to be difficulties of deglutition, the manner in which a child that is extremely sensitive to pain is to be sponged and bathed, and the manner in which the limbs are to be placed so as to avoid increasing pain or early contracture—all these conditions call for expert handling. And if the American Public Health Association or the health board of this city intends to enlighten the public, it would be well to avoid expressions that are very much more apt to harm than to benefit the public. Without specifying, this same health committee also states that "active measures" during the persistence of the acute symptoms of the disease are not only useless, but are apt to cause serious or even permanent injuries. Some of us may have some reasonable doubt as to what the committee meant by "active measures." I am glad, however, to note that the committee concedes that the "best chances of recovery from residual paralysis demand skillful aftercare."

In the early treatment of the furibund and of the meningeal cases the question arises whether anything can be done to avoid a fatal termination. Let lumbar puncture be done, noting the effect of each puncture. In every such case the immediate administration of an immunizing serum, as recom-

mended by Netter (11) and Flexner (1), should be tried. The latter believes that it would be advantageous "to take the serum of persons whose attack was less remote so as to insure as high concentration of the immunity bodies as possible. Doses ranging from five to twenty c. c. will be found suitable, the injection to be repeated several times at twenty-four hour intervals according to clinical conditions and indications." All the usual precautions are to be observed as to Wassermann reaction of serum, etc. That it has been of use in some instances cannot be denied, but some of the statements that have been made in its favor must be judged with full knowledge of the fact that without serum injections many of the cases that begin in furibund fashion subside quickly.

I have been much impressed by Meltzer's (9) thoughtful contribution on the treatment of acute poliomyelitis. In the cases in which cardiac or respiratory paralysis is threatened, artificial respiration, if possible by Meltzer's method of intrapharyngeal insufflation, should be maintained for some time; and, by the way, why not use oxygen directly when there is the slightest difficulty in respiration? And I am also willing, on the strength of Meltzer's arguments, to allow that in future epidemics a further test be made of the administration of adrenaline.[5] That the rapidly advancing edema of the nerve tissues is an important factor in the causation of the symptoms there can be little doubt, and whatever experience others may have had with this treatment, there is surely a rational basis underlying it. Many cases were treated successfully according to Meltzer's method at the New York Throat, Nose, and Lung Hospital. Meltzer advises that two c. c. of a one to 1,000 adrenaline solution should be injected every four to six hours.

As for the use of hexamethylenamine in these earlier stages, opinion is still divided. The best that can be said of it is that the administration, aside from the occasional hematuria which it causes, is entirely harmless. But no one will hold that it has direct specific effect.

Let us hope that before another epidemic occurs we shall have advanced still further along the road of obtaining a positively immunizing serum, and that the number of rapidly fatal cases in any future epidemic will be greatly diminished. Properly equipped hospitals and well trained staffs will be of the greatest importance. Now that the epidemic is over we are face to face with the serious problems connected with the aftercare of children and adults suffering from paralysis due to this affection. Let us consider very calmly what we as conscientious neurologists can recommend.

First, with reference to the subject of electricity. What are the essential and incontrovertible facts in the case? Whatever opinion we may entertain as to the therapeutic value of electricity, we are all agreed, I am certain, as to the great value of careful electrodiagnosis. In every instance an electrical examination with the faradic and galvanic currents should be made of every group of paralyzed muscles. I know of no better way of answering the question, whether or not a muscle or group of muscles has a chance of recovery, than by determining the electrical response of such muscle or group of muscles. If after the lapse, say of the first four weeks, any nerve or muscle of a definite group still responds to faradic stimulation, it is fair to say that that muscle or group of muscles will recover completely in due course of time. If the responses are present but very much diminished, both to the faradic and galvanic currents, the recovery will be relatively slower. If there is partial reaction of degeneration, there is hope of recovery only after many months. If any muscle or group of muscles shows a complete reaction of degeneration with slow, wormlike contractions, with considerable wasting, then the hope that such muscles will recover is a very faint one, but even after many months the electrical conditions may improve and thus give hope for further improvement. I consider the proper electrodiagnostic examination of a case of poliomyelitis the duty and the privilege of the specially trained physician, and I know that there are few others who can be depended upon to make such examination. After having determined this point, then the tonicity of the muscles, the blood supply of the extremities—a point so often disregarded—the indications of the presence or absence of the slightest volitional innervation will be of great additional value.

Aside from the electrodiagnostic value, electricity will prove especially useful in stimulating muscles which are absolutely paralyzed, but are still responding to some form of galvanic excitation. Many paralyzed muscles can be exercised in this way and in this way only. The perfunctory use of faradic stimulation in the more serious forms of poliomyelitis is senseless and painful, but whenever it is found that muscles react to faradic stimulation, that form of current may be employed just as readily as the galvanic.

Our conclusion, therefore, is that the chief use of electricity, aside from its great use for the purposes of diagnosis, is in exercising all muscles which cannot be exercised by the will. We shall still plead for the intelligent use of it in a certain number of cases of poliomyelitic patients whose muscles cannot be exercised in any other way. The indiscriminate use of electricity as a remedial measure in all cases is as irrational as is the absolute condemnation of electricity as a measure scarcely worth considering. This leads us to a consideration of muscle training and educational exercises in general as the proper method of treating the paralytic cases.

Neurologists have long since recognized that exercise is the best form of treatment for a paretic muscle. Fastening upon the slightest beginnings in the return of volitional power, a muscle or a group of muscles is encouraged to improve by the careful repetition of appropriate movements.[6] This means practically that in every case the physician examining a patient must indicate the exact exercises that are to be performed up to the point of easy fatigue —not beyond that point. Dispensary or hospital

[5] Meltzer makes handsome acknowledgment of Fraser's previous attempts to use adrenaline on the human subject. In eight cases in which "there was extreme respiratory involvement" this line of treatment was tried (1-1.5-3 c. c. to 1000 was the strength employed with an equal amount of saline). Five of the eight cases ended fatally.

[6] For details, cf. *Report of New York Investigation Committee*, 1910.

divisions equipped with Zander apparatus would prove of great help in this matter. The patient exercising and patient training of the muscles can be carefully indicated by the physician, and must then be carried out either by a competent nurse or by the mother, if she can spare the time and if she has the ability to carry out the directions of the physician.

A word also in favor of rational massage to be given after warm baths. It will help to improve the circulation in the paralyzed limb and may tend to prevent undue wasting of the muscles.

Our public duty in this matter is to discourage excessive dispensary visits, unless it be in the relatively few cases that need regular and persistent electrical or Zander treatment. In all other cases an occasional visit to the dispensary—say once a week or once a fortnight—will prove sufficient, but the directions given at such a time should be carried out carefully and intelligently.

In this city there is now a movement afoot to spend a great deal of money on ambulances and automobiles which are to bring mothers and their little patients from distant parts of the city to various dispensary classes. Let us, by all means, encourage this sort of philanthropy, but let us state distinctly to the public that this matter should not be overdone and that far more good will accrue to the victim of this disease if some of the funds to be invested will go to secure visiting nurses[7] who will either carry out physicians' directions in the home of the patient, or who will, from time to time, teach the mother or other relative to conduct such exercises as the physician has indicated.

Aside from the waste of public moneys, I am also impressed with the waste of time and energy on the part of hundreds of mothers who are expected to drag their children to dispensary classes two or three times a week for the sake of perfunctory electrical treatment or for the sake of easing their consciences that they are giving their children the best possible care. The crying need in this city at the present moment is an ever increasing staff of *visiting nurses* under proper medical supervision, and we neurologists can afford to set the public right in this matter.

Lastly, let us take up the matter of orthopedic treatment. The public has been led to believe during this past epidemic that the orthopedist is the one specialist to whom all these cases should be referred. I have no wish to deprive him of any of the glory that may accrue to him from this popular misconception, but I have serious doubts, if this method is adhered to, that it will be for the greatest good of the greatest number of children. I allow that wherever there is the slightest tendency to deformity, whether in the earlier or in the later stages of the disease, wherever it is found that it will be impossible for the child in any way to use its upper or lower limbs without some special orthopedic appliance, that the judgment of the orthopedic surgeon be accepted in the most liberal spirit. But, in view of the importance which the neurologist attaches to the matter of exercise of paretic muscles, the question that must seriously be considered in every case is whether the partial or permanent immobilization of a limb will permit an early return of power on the part of such paralyzed or partially paralyzed muscles. Permanent orthopedic appliances—splints or braces worn continually—must be regarded with suspicion in cases in which there is good reason to think that considerable improvement will ensue from the careful training of muscles. The child with a Punchinello leg, with thigh and leg muscles that are thoroughly wasted, or the child that in its attempts to stand shows a marked genu recurvatum, will, of course, need its braces, and the children whose deep spinal muscles have been affected by the disease, and who are in danger of marked distortion of the spinal column, will also require proper splints and braces. Lovett (4) says that "braces, corsets, and other forms of apparatus are compensatory rather than therapeutic." Braces prevent "muscular stretching and the loosening of joints, and control deformity." No one could be more thoroughly in favor than I am of the surgical orthopedic measures that have been employed so successfully in the transplanting or in the shortening of tendons and in nerve transplantations. As I said in a discussion some time ago, there are very few chronic paralytic cases that can be carried through from beginning to end without the need of orthopedic opinion and treatment, but it is in these cases of moderate or slight paralysis that the best interests of the patient will be subserved, in my opinion, if orthopedic appliances are not resorted to too early or too persistently.[8] In this matter there should be the most amicable cooperation between the neurologist and the orthopedist.

So far as the after care of the large number of victims among the children of the poor is concerned, I believe we neurologists will do well to insist that special classes at the various dispensaries be arranged for these children; that they be examined first by men with competent neurological training; that the matter of electrical treatment, of muscle training and exercise, possibly of massage, be carefully considered, and that the treatment be outlined in friendly cooperation between the neurologist and the orthopedist so as to bring about the best possible results.

Finally, let us impress upon the public the fact that while the epidemic disease is serious and its results are often most appalling, many of the children are capable of a vast amount of recovery. And let us in that way, also, minimize, if possible, and counteract the panic which seized the public because of the public announcement of every case.

116 WEST FIFTY-NINTH STREET.

SOME SOUTH AMERICAN TRAVEL NOTES.

By AUGUST SCHACHNER, M. D.,
Louisville, Ky.

Impressions of a country gathered during a somewhat hurried tour are not without value, because, when they are so gathered, conditions appeal strongly to the traveler, and such impressions might in time become less emphatic through continued contact.

It seems safe to say that the vast majority of North Americans know more, think oftener, and visit more eagerly any of the European countries, or even the Orient, than South America. Yet the European countries have scarcely any claim upon us, certainly not in comparison with South America, which should attract us politically, economically, and scientifically; and what is more novel, is just as interesting and fully as beautiful as Europe. Custom and convenience are the chief reasons for this anomalous condition, and it is idle to expect a change until we have better and faster means of communication.

We can hardly realize the possibilities of South America viewed from any angle, nor can we bring about that close relationship which for entirely logical and natural reasons should exist, until we have these improved means of communication. We are as strange to the South Americans as they are to us, and this mutual strangeness can be overcome only by contact.

Europe has long since recognized these opportunities, and improved her means of communication with South America; in fact, Americans have to a certain degree, and not altogether wrongly, been trained to the idea that it is easier to go to South America via Europe than it is to go directly. We have already allowed many of our opportunities to slip from us, therefore we should now redouble our efforts that we may regain some of our lost advantages, as well as establish a relationship that is perfectly natural and far more logical than the commercial alliance that exists between South America and most of the European countries.

Few of us realize that our neighbors, with but one exception, and practically all of our colonials speak Spanish. In view of this, and since South America should be our most important field of activity, what would be more reasonable than the introduction of Spanish into our high schools?

Of greater importance, however, is the establishment of a steamship line worthy of the name between the United States and South America, and the completion of the Pan-American Railroad at the earliest opportunity.

So long as it takes nineteen days with indifferent comforts to reach Rio de Janeiro, and about five days more Buenos Aires, there will not be any overwhelming incentive for tourists to switch from Europe to South America.

FIG. 1.—A partial view of Rio de Janeiro.

There is no good reason why the present conditions could not be improved one hundred per cent., both as to time and comfort, and then, with the proper publicity, we should see a drift of tourists to South America that would in a short time bring quicker results than all the bureaus, congresses, pamphlets, etc., that after all are only second hand in their effect and of long range in their action, contrasted with the vivifying influence of actual contact.

One of our cabinet officers, on a recent visit to South America, strongly and properly spoke in behalf of the Pan-American Railroad, which was at once ridiculed by the *West Coast Leader*, which referred to it as "a chimera."

This attitude on the part of the *Leader* was entirely human. It would be unnatural to expect the English, who have been strongly intrenched in this productive field, to view complacently the oncoming Americans after having been so keenly grilled in a commercial way by the Germans for the last decade.

There is nothing that would be so productive of

Fig. 2.—Oswaldo Cruz Institute; the main building.

results as the completion of this railroad, which is strongly analogous to the Cape to Cairo railroad. There is a stretch of approximately 10,000 miles from New York to Buenos Aires, of which about 7,500 are in operation.

Obviously, it would mean further climatic engineering and economic problems, just as the Panama Canal did, but to complete the remainder of the railroad and further adjust that which is already built would not begin to be the same problem that the Panama Canal was, and would perhaps yield greater results than the canal will yield, so far as America is individually concerned. With all this should go the creation of a real merchant marine, as it is childish to build up a trade that would be dependent upon the generosity of our competitors.

It seems needless to recall that south of the equator the seasons are reversed, so that while it is summer in the States it is winter below the equator, and my tour was confined to that part of South America south of the equator. Lack of space permits only of reference to the most important places and their most important points.

BRAZIL.

Brazil, a country as large as the United States, with Alaska omitted, affords, through its location and topography, a variety of climatic conditions, and with it a corresponding variety of diseases. Naturally the important centre here, is Rio de Janeiro. It would be an error to pass unnoticed the natural beauties of Rio. If there is one place in the universe that suggests a stubborn resolution on the part of nature to create a riotous centre of natural beauty, that place is Rio de Janeiro. It matters little whether it is viewed at dawn with the lowering clouds draping the projecting peaks in a fleecy mist, or seen in the full glare of the tropical sun, or toward twilight, when the sun lowers its rays, with its peaks in strong illumination and the valleys in soft repose, restfully suggesting the approaching night, or lastly, looking down upon it through darkness from the mountain side with the twinkling brilliancy of its countless lights, that suggest an inverted heaven, studded with stars of the first magnitude, it is always beautiful.

At Manguinhos, a few miles outside of Rio, is the Oswaldo Cruz Institute, which, on account of its distinct knowledge of the diseases common to the tropics and of the pastoral element of this country with its animal diseases, and some 300 varieties of biting flies, supplies an imperative need, and is one of the most important assets of the Brazilian government.

The institute is named after Dr. Oswaldo Cruz, who is still its efficient head, and who cleaned up Rio and made yellow fever a thing of the past. His *Chef de servico* is Dr. Adolph Lutz, who, together with a capable corps of investigators, is doing splendid work, covering a broad field of activities involving both animal and plant life. The institute is a small community in itself, in which not only the sci entific work is being conducted, but the illustrating, printing, and binding are all under the same roof.

A problem is decided upon and divided up between the various members of the staff, and at a given time each makes his report and the work of all is discussed in joint session.

The researches of Carlos Chagas on *Thyreoiditis parasitaria* bearing his name have aroused considerable interest, especially on the east coast. Through the kindness of Dr. Alvaro Ramos, a number of cases were shown to me in one of the departments of the insane asylum. The condition is one of cretinism, believed by Chagas to be due to the presence of trypanosomes, Schizotrypanosoma cruzi.

There is a feeling in some quarters that is not to

Fig. 3.—One of the animal houses of the Oswaldo Cruz Institute.

be ignored, that some of the work requires revision, and that it is not satisfactorily settled that the presence of the trypanosomes is responsible for the existing cretinism, but rather that it represents an incidental feature of the condition.

The hospital in which Doctor Cruz did his yellow

fever work is still in existence, but without a patient, and in its empty state is a mute reminder of the days when grim conditions were not uncommon in this scenic paradise. With great interest, the staff described the mosquito brigade and demonstrated the screening and automatic arrangements permitting ingress and egress to and from this hospital, at the same time protecting it from the entrance of Stegomyia fasciata.

FIG. 4.—Bacteriological Institute at Buenos Aires.

The principal hospital is the Santa Casa Miseracordia, with a capacity of 1,500 beds. The hospital is beautifully situated near the water, shaded with an arcade of trees, Fica benjamina. The hospital, in common with hospitals of Spanish and Portuguese countries, has a number of large courts filled with flowers. The floors are of waxed mahogany, and present a clean and serviceable appearance. The nursing is in the hands of Sisters of Charity, but a training school for nurses is being organized. Spinal analgesia is freely used here, as well as throughout South America generally, and we feel that we should use more of it than we do. Generally stovaine is the drug employed. Where general anesthesia is resorted to, the Roth-Drager apparatus is usually given preference.

Through the kindness of Professor Daniel D'Almeida, the surgical service was made accessible. The medical school has an attendance of 2,000, and it may be added that there is a school at Sao Paulo with 300 students and others at Bahia, Porto Alegre, and Bello Horizonte. The writer could not refrain from explaining the conditions that exist in the United States as the result of overcrowding, to which was quickly answered, "We have been warned and are taking steps."

In Sao Paulo, the second city in Brazil, there is the Instituto de Butantau, or, as it is familiarly known, the Snake farm. Here are seen snakes of all kinds, sizes, and degrees of virulence. They are handled and looked after as carefully as the blooded stock of some breeding farm, and occasionally a snake fight is staged between one of the harmless variety and a poisonous snake, in which the latter is destroyed.

Provision is made to receive snakes from any part of Brazil. Their virulence is tested and classified. The object of the institute is to study and classify the snakes of Brazil and prepare a serum to counteract the bites of poisonous snakes. It requires about six months to prepare the antitoxin in a horse for use in snake bites, and it is freely sent to any part of Brazil where it may be needed.

The hospital here, like the one in Rio, is known as the Santa Casa Miseracordia. Here some further light upon cases of chagras, leprosy, and leishmaniasis, was obtained through the kindness of Dr. Alexander M. Pedroso.

ARGENTINA.

Buenos Aires, the metropolis of the Argentine, the largest city in South America, the fourth largest in the western hemisphere, and the second largest Latin city in the world, is cosmopolitan, solid, busy, important, and has all the swing of a metropolitan centre.

The chief point of interest here is the Instituto Bacteriologico in the Departmento Nacional De Hygiene, which is under the able supervision of Professor R. Kraus, of Vienna. The institute has been in existence for a number of years, but has been installed in its present complete and imposing quarters only since July, 1916.

As the Argentine is mainly a pastoral country, and live stock represents its chief product, the institute very properly is as much dedicated to the study of diseases of animals as of man, especially as some of the diseases afflicting the human race are acquired from the animals, notably anthrax. The institute is the last word in its line and is complete so far as its interior and exterior arrangements go. It is also well supplied with animal houses, including a snake house. The animal side is fairly well balanced against the human side. Just as these various houses for the treatment and study of animal diseases exist so is there a hospital consisting of a number of pavilions for the treatment and study of the various infectious diseases.

The entire arrangement complete, concentrated, and practical, represents a centre of absorbing interest to any medical man. The institute, beside covering this wide field, prepares an ample supply of vaccines and serums for the Argentine, and holds itself ready to assume the control of any epidemic emergency that may arise in this extended country with its large and mixed foreign element. In the pavilion for anthrax, cases of varying severity were

FIG. 5.—Section for the study of bubonic plague at the Bacteriological Institute at Buenos Aires.

shown, and the success achieved in the treatment with their serum is highly creditable.

The leprosy pavilion provided interesting material for the study of this condition. Some of the milder cases were outside in the sunshine. So far no headway has been made through the injections, more especially of mixed strains. Professor Kraus, while exhibiting these, significantly added, "Of course you have more leprosy in your country than most of you think"—a statement that will receive rather general endorsement.

Cases of leishmaniasis, a protozoal disease named after Major Leishman, of the English Army, and representing a form of trypanosomiasis, is said to be a common condition among the South American Indians, possibly more so in the low countries or Montanas than in the greater altitudes, although a case of unusual severity was shown the writer in Cuzco, Peru, at an altitude of about 13,000 feet. The native physician who brought the case emphasized its prevalence among the Indians. Its existence among these Indians, whose trials and tribulations are many, and whose cup of sorrow has long

Fig. 6.—A scene in Cuzco, Peru, the ancient capital of the Incas.

since overflowed, makes their lot a truly pathetic one. It is said that many of the cases falling into indifferent hands are commonly mistaken for lues, and it would not be surprising, judging from the appearances of advanced cases, if they were confounded with malignant disease.

Excellent results are achieved in this condition through the use of tartar emetic, administered like salvarsan. It seems needless to say that a very small percentage of the cases ever receive such intelligent treatment, if any treatment at all, and so the disease continues to spread and destroy with practically no restricting influence.

The writer is indebted to Dr. M. J. Barilari, Jr., for his unsparing efforts as a guide to the medical side of Buenos Aires. The medical school has an attendance somewhat less than that of Rio, but still sufficiently large, if we consider the existence of a second one at Cordova, to make the criticism expressed at Rio, hold here. It occupies an entire block, and is architecturally imposing. It is of such a size as to require some hours to examine even superficially its departments, laboratories, museums, and libraries. The public morgue is in connection with the medicolegal department, and is so arranged as to give the public and the profession the best results.

The medical charity of the entire city is under the supervision of the Assistancia Publica, patterned after its prototype in Paris. Although Paris is still, to a considerable degree, the apple of the Latin-American eye, it would be a misrepresentation to ignore the fact that the medical, military, and mercantile classes of South America have discovered Germany, and just as the armies of several of the South American countries have been under German supervision for years, so the medical side of Latin-America seems to have been gradually coming under the dominance of German thought and action.

The surgery we saw in the service of Doctor Finochetti at the Rawson Hospital was not without interest.

URUGUAY.

Montevideo, the capital of the smallest, but one of the most progressive of the South American countries, is the only place where the American dollar is at a small discount, instead of being at a large premium. So far as my observation went in medicine and other public departments, everything seemed of the latest and highest order. Their penal institution, which I was persuaded to visit, was ideal, possibly without a superior, and most likely with few equals. The old hospitals were being replaced by new and modern ones, and the medical school is imposing and palatial.

In South America generally, they are proud of their laboratories, especially the Röntgen laboratory, but the only place where radium was in evidence (most likely, however, not the only place it was being used) was Montevideo. Here it was extensively employed in the laboratory of Dr. Carlos Butler, who has given the cancer problem in Uruguay some attention, and outlined his results in an address before the first National Medical Congress held in Montevideo, April, 1916.

The Cordillera so completely divides South America into two unequal parts and the changes are so evident that we almost feel that we have passed from one continent to another.

It is as "the West Coast" that the South American generally speaks of the part west of the Andes.

CHILE.

Santiago nestles in a semitropical valley in the foothills of the Chilean Andes, and in panoramic view of a beautiful chain of snow capped mountains. There is but one medical school in Chile, situated at Santiago, and it has an attendance of 600 students. The three large hospitals are the Hospital San Vincente, which adjoins the medical school and has 600 beds; Hospital Del Salvadore for men and women, with a capacity of 750 beds, and the Hospital Sanborga, with 750 beds, and exclusively for women. They are all attractive hospitals and doing good work, but the Hospital Sanborga deserves special mention because of its patio or court, which was the most beautiful patio that has ever been brought to my attention.

BOLIVIA.

The next move took us into Bolivia, known as the hermit kingdom, because of its completely inland situation.

Traveling for forty-eight hours, most of the time

on a thirty inch gauge railroad, which was entirely comfortable, however, and climbing from sea level to a barren plateau, 13,000 feet high, past smoking volcanoes and mammoth borax lakes, brought us to the abrupt rim of a canon, at the bottom of which, 1,200 feet below, lies one of the unique cities of the world, La Paz, the capital and metropolis of Bolivia.

Neither Bombay or any oriental city can outdo La Paz in its display of bright colors. With its ever moving masses of Indians and Cholas (mixed breeds), each trying to outdo the other in gaudiness of dress, its irregular situation, as its were, hanging upon the slopes of the canon that screens it from the howling blasts upon the plateau above, and under the shadow of Illimani, whose frozen summits are pushed 21,000 feet into an azure sky, it presents a scene, and, in the rarified air, a sensation that will never be forgotten.

What a splendid opportunity this city could afford for a critical study of the effects of extreme altitudes on animal life. We do know some of the changes, in fact, they are apparent, such as diminution in size of the people, and other effects that are not apparent, such as the increase in the hemoglobin. But the subject has never, to our knowledge, been as fully studied in all its ramifications as it deserves. The birth rate and infant mortality of these elevated regions are perhaps the highest in the world, and if the latter were not the case, it would doubtless be one of the most thickly settled of regions.

The entrance of the hospital in La Paz leads into a large paved patio, part of which is surrounded by wards for the insane, while the remainder is used for storing the funeral outfit, hearse, carriages, etc. Beyond this first patio, comes the hospital proper Primitive as it is inclined to be, it affords care and protection to the sick Indian. The Indian collectively, or regionally considered, represents an interesting problem, and in his present state he fulfills in South America the complete definition of the white man's burden. As we see him, especially in the high and remote regions of this extensive land, with his short, stocky stature and muscular development suggestive of iron, carrying the mail across the cold and tractless plateau, or racing in an altitude in which a foreigner is quite content to be able to slowly move about, with a face full of resignation, we find ourselves almost forgetting that he is a human being. Aside from the barest necessities of life, all his ambition seems to crave is his jar of chica, or fermented maize, and the ever present "cud" of coca leaves, without which he will do almost nothing, and with which no burden seems too heavy, he forms a most interesting and pathetic figure in human affairs.

In concluding these incomplete, fragmentary, and disconnected notes, we hope that they will help to attract attention to a vast region crowded with unlimited problems, resources, and interests of every variety. Buried and forgotten cities represent a civilization comparable to our own, and with the passing of which disappeared the secrets of a superior race. This should arouse in us an interest that has been unpardonably feeble in the past, and that deserves to be translated into vigorous action without further delay.

THE SURGICAL TREATMENT OF GOITRE.*

By J. Walter Vaughan, M. D.,
Detroit.

Obviously it is impossible to present in the space at my disposal much that is essential for a proper consideration of so broad a subject as the surgical treatment of goitre. As a consequence I will limit my portion of this symposium to a presentation of what experience has taught me to believe is the proper surgical treatment of these cases, together with a few remarks upon the research work that is being carried on at present in the Buhl Memorial Laboratory of Harper Hospital.

It is now quite generally conceded that the colloid contained within the vesicles of the thyroid gland represents, or is the active principle in the secretion. Bensley (Normal Mode of Secretion in

Fig. 1.—Lateral displacement of trachea in substernal goitre.

the Thyroid Gland, *Amer. Jour. Anat.*, xix, 37, 1916; editorial article, *Journal A. M. A.*, May 27, 1916) has traced histologically the method of formation within the cell and the disposal from the cell of the intracellular colloid which he calls the "secretion antecedent." In brief, he asserts that the secretion occurs in vacuoles in the outer pole of the cell, and from there is transported directly into the vascular system. Obviously this fails to account for the colloid found within the vesicles, and Bensley states that in addition to the secretion from the outer pole of the cell, there is also an indirect mode, which consists of the extrusion of droplets into the vesicle, thus forming its colloid content. Thus the vesicles simply act as storehouses for the active thyroid principle when its rate of production is in excess of the body needs, and, conversely when the body needs are in excess of production, the stored colloid is available.

This conception of the formation and distribution of the active thyroid substance is of decided

*Read at the seventeenth annual meeting of the American Therapeutic Society, Detroit, Mich., June 10, 1916.

interest when applied to the pathological pictures in thyroid disease known to be associated with either a hypothyroidism or a hyperthyroidism. In

Fig. 2.—Lateral tracheal displacement caused by substernal goitre.

connection with the former, Morse (*Jour. Lab. and Clin. Med.*, 1, 4) has shown that in pellagra there is probably a more complete destruction of normal thyroid tissue than is found in any other disease

Fig. 3.—Fusiform trachea with lateral displacement caused by substernal goitre.

condition. He describes the changes as a sclerosis and round celled infiltration. There is a striking overgrowth of connective tissue with almost complete destruction of normal thyroid cells, and what areas of thyroid tissue are left are cut off from their normal close contact with the blood supply and are destroyed by the pressure of the surrounding connective tissue.

Though the foregoing may appear to be somewhat foreign to the subject, I have made reference to it because it illustrates best the type of gland in which the ability to form a normal active secretion is at its lowest ebb. It is the extreme limit of hypothyroidism from a standpoint of microscopical glandular pathology.

Parenthetically it might also be stated that the work of Morse suggests that pellagra is the ideal disease in which experimental surgical work in the implantation of normal thyroid gland tissue should be carried on.

From the study of Bensley's work it can be readily seen that a hypothyroidism may be accompanied with a greatly decreased amount of intra-

Fig. 4.—Fusiform trachea caused by pressure of substernal goitre.

vesicular colloid as in pellagra, the decrease being caused by a destruction of normal gland cells. Again this same condition may also be associated with a considerable increase in the amount of intravesical colloid as is occassionally observed in diffuse colloid goitre. In this latter case it is quite probable that there is a definite change in the chemistry of the colloid itself which is evidenced by its altered physical characteristics. Whether this is true or not, we are justified in assuming that a mechanical factor also enters into the phenomenon of hypothyroidism associated with simple goitre, since increased pressure within the gland must of necessity interfere with the proper functioning of gland cells upon which the greatest amount of pressure is exerted. This in itself would explain the greatly increased amount of apparently normal thyroid tissue so frequently observed in this type

of goitre, it being the result of a compensatory hypertrophy.

When we turn our attention to an examination of the thyroid cells in hyperthyroidism, we observe that they are much enlarged, usually being much higher than in the normal gland type, their periphery is much darker and the intravesicular colloid is decidedly lessened. There is also a perivascular round celled infiltration. In other words, we have hyperactive secreting cells which are discharging constantly more than a normal amount of colloid directly into the circulation, together with an inflammatory picture which I will refer to later.

In general it might be stated that all cases of hyperthyroidism should be subjected to surgical removal of a sufficient amount of gland tissue so as to diminish the amount of colloid entering the vascular system to as near the normal as possible, and conversely that no case which shows definite signs of hypothyroidism should be permitted to lose any functioning gland tissue.

Such a rule would be exceedingly simple were

Fig. 5.—Involvement of trachea in carcinoma of thyroid gland.

it not for the fact that occasionally cases are met with in which there are present definite signs of both hyperthyroidism and hypothyroidism at one and the same time. Such cases have been of the Graves type for so long that their ability to form the amount of colloid required for normal needs is almost exhausted, and yet during exacerbations of the disease the amount formed is still excessive. This is particularly true in the type of case that is termed secondary exophthalmic goitre accompanied with marked exacerbations and remissions. By secondary exophthalmic goitre I mean those cases which previous to the appearance of one or more of the symptoms which characterize Graves's disease, possessed some cystic or adenomatous enlargement of the gland.

Primary exophthalmic goitre I would classify as those cases in which the thyroid enlargement and other symptom complexes occur simultaneously. That such a distinction is important clinically was well shown in a paper presented by Doctor Ballin

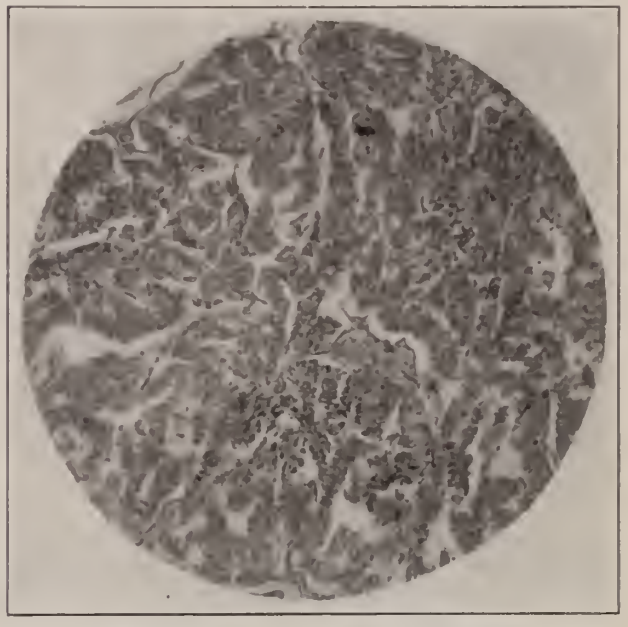

Fig. 6.—Microscopical section of carcinoma simplex of thyroid gland.

and myself seven years ago (Final Results of Thyroidectomy for Exophthalmic Goitre, *Journal M. S. M. S.*, 1909), in which were given twenty-one cases of the primary type with five deaths, and twenty-six cases of the secondary type without a death. Many of the cases in the latter class were clinically as severe as those found in the primary class, yet the risk of operation was much less. This is probably

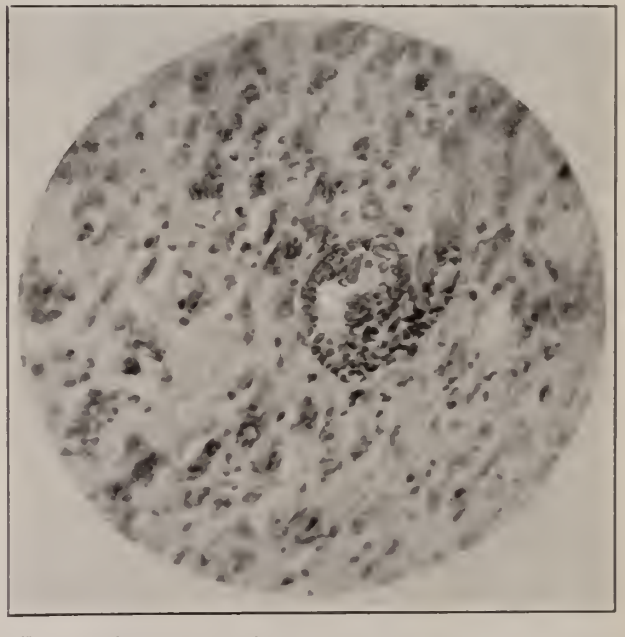

Fig. 7.—Tissue removed from same case as specimen from carcinoma simplex, taken two months later when growth of tumor was very rapid. Here it would be called a spindle celled sarcoma.

due to the fact that owing to the goitre formation, the actual amount of hypersecretive tissue is much less in the secondary than in the primary type.

Probably the most valuable aid given in recent years for the proper treatment of the severe primary type is the boiling water injections advocated by Miles Porter. It is now my practice in patients suffering from severe symptoms at the time of entrance into the hospital, to place them at rest, confined to their beds, with ice bags over both thyroid gland and heart. Frequently, after twenty-four hours to one week, the acute symptoms have subsided sufficiently so that operation may be performed without risk. This brings the operation between exacerbations of the disease and is termed the interval operation. If the pulse rate and nervous symptoms do not subside, however, in from seven to ten days at the utmost, then the case is one that should be treated by Porter's method. Since adopting this procedure I have not had a death. One case improved so much after the injection of boiling water that the patient refused subsequent surgical removal and for two years has remained clinically well.

In all fairness it should be stated, however, that

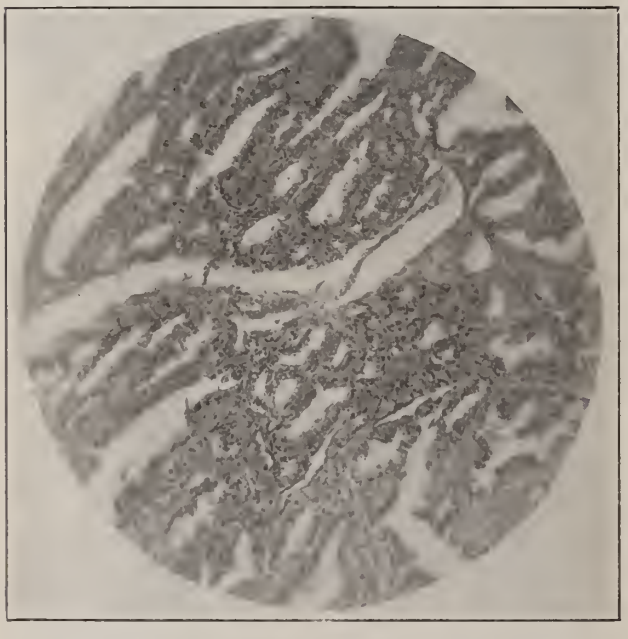

Fig. 8.—Microscopical section of exophthalmic goitre.

I do not see the severe cases at present that we had so many of formerly. Physicians in general, I believe, are advising operation earlier now in exophthalmic goitre than they formerly did, and surgeons are consequently obtaining a higher percentage of good recoveries and reducing greatly the mortality.

One point that does not receive sufficient importance in the diagnosis of Graves's disease is the accompanying monocytosis. Kocher, I believe, first called attention to the fact that in all cases of true exophthalmic goitre the relative number of polymorphonuclear leucocytes is greatly reduced, while the percentage of lymphocytes is correspondingly increased. It is interesting to note that after surgical treatment for this type of goitre the differential count quite readily readjusts itself to normal in conjunction with the improvement in nervous and cardiac symptoms.

Because of the blood changes, and especially because of the perivascular round celled infiltration observed in sections of an exophthalmic goitre, we are of the opinion that the disease is inflammatory in origin. All sorts of theories have been advanced concerning the etiology of hyperthyroidism, and much stress has been laid upon the pos-

sibility of its being either toxic in nature or associated with a deficient secretion of some of the other glands of internal secretion. For the past few months Doctor Morse has cultured all fresh exophthalmic goitres sent to the pathological laboratory at Harper Hospital by Rosenow's method. Only two of true primary type have been received, and both have yielded Streptococcus viridans. Several of secondary type have been cultured, but all have so far been negative. Space does not permit of more detail, but there is much evidence to support the infection theory.

Just one more word about Graves's disease. Formerly it was our rule to remove the largest lobe together with the isthmus and pyramidal lobe or not, as the case seemed to require. In a few cases symptoms recurred after an interval of freedom, and a partial removal of the remaining lobe was necessary

Case 5—

to bring about a cure. Now it is my practice in relatively severe cases to remove the greater portion of both lobes, together with the isthmus and pyramidal lobe, and I believe that the results justify the more radical procedure.

Most goitres that the surgeon sees are of the simple or adenomatous type, and are presented for operative procedure for cosmetic reasons. Outside of the thyroid enlargements associated with puberty, and those diffuse varieties which are sometimes improved by the administration of iodine, all goitres should be treated surgically.

When surgical intervention is advised, early operation is practically without risk, but when delayed until the tumor is of such size as to interfere with respiration or deglutition, it makes the task more difficult. The accompanying plates, which have been made by Doctor Hickey, show well some of the

deformities frequently associated with large neglected or overlooked intrathoracic goitres.

In conclusion, let me state that it is my belief that any abnormal tissue should be considered as being potentially malignant.

Cancer of the thyroid almost invariably presents a history of a quiescent tumor before rapid growth

and, once actual malignancy is established, owing to the impossibility of removing the entire gland and its capsule, operation is of no practical avail.

One accompanying section (Fig. 7) shows a carcinoma simplex which after incomplete removal recurred rapidly with a change to a sarcomatous type of cell.

Kresge Medical Building.

THE ALLEGED PASSING OF THE HYPOPHOSPHITES.

By Thomas J. Mays, M. D.,
Philadelphia.

In its arduous work of refining our materia medica, the Council on Pharmacy and Chemistry of the American Medical Association recently determined to place the hypophosphite preparations on its expurgated list, for the reason "that the therapeutic use of 'these drugs' (except possibly in some cases as a convenient means of administering the positive element in the salt, as ammonium in ammonium hypophosphite) is irrational." (See *Journal A. M. A.*, September 2, 1916, p. 760.)

It must be confessed that this is rather a startling indictment, especially to those who were suffering from the possible deception that these agents had found some sort of a settled place in our medical armament, but, in view of what has recently taken place in the bosom of our Chicago friends, anything but the expected may be looked for.

Why is it "irrational" to give the hypophosphites? "Because," the council says, "there is complete or practically complete elimination of them in the urine," and, therefore, they can have "little or no effect on the body"? Is it the conviction of the council that it is essential for a substance to undergo a chemical change in the body before it is capable of exerting any "effect on the body"? If this were true, how is it possible for the vast majority of our most active medical agents, like strychnine, morphine, aconite, cocaine, etc., to influence the bodily functions? So far as we know, they are all excreted in the proportion in which they are administered.

It appears, however, that when we view this matter aright, the announcement of a "practically complete elimination" is a horse of quite a different color, and actually means that only eighty-five per cent. of the ingested hypophosphites is excreted, and that, consequently, fifteen per cent. remains behind. Is the fifteen per cent. supposed to become inert and passive, or is the council following the fate of the ataxic, who stumbles and falls over his own heavy feet? When we reflect that Nature is quite an extravagant mistress in her biological operations, and that, according to Helmholtz, only twenty per cent. of the food that is consumed by the human body is turned into useful work, will any one be rash enough to assert that fifteen per cent. of a rather active drug is without influence when it is brought into contact with the impressible tissues of the body?

What, then, of the fifteen per cent. proportion of the hypophosphites, which, according to the council's own expert, is set loose in the body? Is this modicum capable of exerting the useful and favorable action of the hypophosphites which is asserted for them by a large majority of the medical profession, or does it lie there destitute of any action or power, thus giving proof to the arraignment that their administration is "irrational and unsound"?

It is hardly credible that any one but this council entertains such a thought, for it bears the mark of improbability on its very face. If the hypophosphites were wholly excreted, or if that portion which remains behind were impotent to make an impression on the animal structures, how do the council and its expert account for the fact that when, for example, three out of five young rabbits received these drugs in doses varying from a quarter of a grain to four grains daily for a month, and the last two received none of them, the average gain in weight of the first three was thirty-eight per cent. greater than it was at the beginning of the experiment, while that of the last two increased only eleven per cent. during that time? Moreover, it is still more remarkable to find that the increase was exactly proportionate to the amount given to each. Thus, the first rabbit received twice the quantity that was given to the second, and the latter received twice the amount that the third one did—and the increase in weight was 41.35, and twenty-seven per cent respectively.

One other point to which attention is to be drawn here: If the council were longer on facts and shorter on innuendo, it would not make the preposterous statement (for such it is, until proof is offered to the contrary) that the therapeutic value which the hypophosphites possess is attributable to their basic contents. If the council is certain of its ground, it should show some experimental evidence to that effect. In the absence of such verification, its conclusion on this point falls flat.

Unfortunately, at the time when Churchill introduced the hypophosphites into England, more than half a century ago, he prejudiced the profession against them, probably by setting up standards for them which it was believed could not be realized. But, in spite of this antagonistic feeling, which in one form or another has been cropping out periodically ever since, they have grown in favor until the present, when they are employed in all civilized countries. It may not be out of place here to recall

the names of the many eminent medical men who investigated the clinical action of these drugs and set their seal of approval on them:

Doctor Darenberg, author of *Treatment of Pulmonary Phthisis,* two vols.: Owing to great loss of phosphates in the urine, and because the calcareous masses in the lungs are chiefly comprised of phosphates in phthisis, he employs the hypophosphites to reconstitute fibrous tissue which contains much phosphate, etc.

Doctor Charteris: While illustrating the value of the hypophosphites in a record of thirty cases, advises the giving of the lime and soda salts alternately.

Doctor Hodgkinson, physician to the Manchester Hospital for Consumptives: In an experience of twenty years with these drugs, he has obtained the best results in the first and third stages, and believes that they distinctly promote the formation of fibrous tissue.

Dr. Wilson Fox, author of *Treatise on Diseases of the Lungs and Pleura:* Confessing that he has made no extended trial of them, states that their value has been supported by authorities of weight, but believes that the cases treated with them would have been benefited by other treatment.

Dr. Theodore Williams, author of *Pulmonary Consumption:* They have proved of great service as tonics, cause gain in weight, and increase in strength, but their tonic effect is greatest when combined with oil.

Doctor Walshe, author of *Diseases of the Lungs:* Found the general health and the amount of flesh improve under their use.

Doctor Cotton, Medical Times and Gazette: Used it with apparent benefit in some cases, but thinks it liable to derange the digestive organs.

Doctor Denoble, of Ghent, Belgium: Gave it to sixteen patients, two of whom became entirely well, and six were very much improved.

Dr. C. J. B. Williams, physician to the Brompton Hospital for Consumption: The hypophosphites seem to increase the failing powers of respiration and circulation. Can this be by increasing the affinity of the blood for oxygen, so that it can attract it and maintain blood changes, even under the increased difficulties and obstruction produced by the disease? Patients who do well under the oil, but who eventually lose ground, will improve in weight and strength when the hypophosphites are added to the treatment.

Dr. J. C. Thorowgood, member of the Royal College of Physicians, London; physician to the City of London Hospital for Diseases of the Chest; author of *Consumption and Its Treatment by the Hypophosphites:* Out of a large experience he gives the details of thirty-five cases, of which he kept a full history, twenty-four of which (or sixty-seven per cent.) were practically well, and ten (or twenty-eight per cent.) improved, and one died. He says that, "having now been in the habit of using the hypophosphites pretty frequently during the last five years, I am able to say that my faith in their remedial power becomes more and more confirmed, while I recognize the fact that they require to be given with discrimination and care."

In reviewing Doctor Thorowgood's work, Doctor Anstie, editor of the London *Practitioner* (1, p. 237), one of the most distinguished medical writers and critics of England, says, "This modest pamphlet is calculated to make a good many people feel rather staggered and ashamed of certain confident assertions which it has been considered the correct thing to make in medical circles, when the hypophosphites, and the notion of their possibly beneficial effect in phthisis, have been mentioned . . . and now we have Doctor Thorowgood, a physician of very large experience as regards phthisis, and of a particularly candid mind, declaring that the results of trials of the hypophosphites, on a very large scale, are decidedly favorable, and that in a considerable number of cases they produce remarkable benefits."

We consider that the arguments hitherto used in this country, and the statistics adduced to prove the inertness of these remedies in phthisis, are simply worthless. We have no formed opinion on this matter. We simply know, from large personal experience, that the hypophosphites are most energetic agents in certain diseases of the nervous centres, and suspect, strongly, that in a very considerable group of cases of phthisis the morbid process takes its starting point from mischief in these very centres. We, therefore, at least, are not at all surprised or flurried at Doctor Thorowgood's calm statement, as the result of his large experience, of his belief that phthisis does frequently so arise, and that the hypophosphites are a perfectly rational, as well as a practically successful kind of remedy under such circumstances. We recommend this pamphlet to our readers' most serious attention. Close criticism it must and ought to have, but we are heartily tired of the bigotry with which the question has hitherto been treated.

In view of what has been brought forward here, where is the council's justification in stating that it was "the overwhelming weight of evidence against the probability that the hypophosphite preparations are of value as therapeutic agents," that led it to think "it well to investigate the subject"? There is no more defense for this than there is for making the audacious and insolent charge that "many physicians" have become such machinelike tools that they descend to the low and servile level of prescribing the hypophosphites "partly from the force of habit and partly because of the power of advertising."

It is hardly comprehensible that the medical profession has really and finally sunk to this moribund extremity in its efforts to differentiate between the useful and the worthless weapons with which to fight disease. Must all the therapeutic knowledge, experiential and experimental, which has accumulated through centuries of careful medical observation, be submitted to a self appointed censorship, the professional knowledge of which is confined to the comparative narrow limits of chemistry and pharmacy, which is presumably oblivious of all clinical experience in regard to these agents, which endeavors to introduce all sorts of illusory and impossible hypotheses to account for the action of drugs, and which is, therefore, no more capable of sitting in judgment on the weighty and intricate problem that

has to do with the art and science of administering medicine, than is the botanist or the biologist, who is also engaged in a calling that is closely affiliated with medicine? It must not be overlooked that when the substances with which these special branches of knowledge deal are applied as curative agents, the new science of pharmacology springs into existence, for the pursuit of which a new mental and scientific equipment is requisite, and to which chemistry, pharmacy, botany, physiology, pathology, etc., are mere contributing agencies.

From the evidence which has been collected in this short discussion, it seems clear that the statements which have been launched by this council with the object of exploiting the worthlessness of the hypophosphites, make a very sorry showing alongside the many valuable therapeutic attributes which these drugs have been shown to possess. Why these agents were selected with the object of illustrating the council's pernicious activity in this direction, is, perhaps, not truly apparent; but, in all candor, it may be affirmed that few other drugs could have been more inappropriately chosen if the purpose was a fault finding one, because not many members of the materia medica have a smaller number of vulnerable points, or possess more lasting and better established claims on scientific medicine than these preparations.

And, finally, it is probably in place to assure the council that the last word on the availability of the hypophosphites has not been said; and to add that, if this body is really imbued with the scientific spirit of enhancing our therapeutic domain—the spirit that endeavors to advance and not to destroy the well attested—it should direct its zeal and attention to the real investigation of the many new and untried measures, and to the improvement of the methods of applying and administering the old. A rich and fallow soil is awaiting its advent.

1829 Spruce Street.

SOME RECENT TENDENCIES IN SURGICAL LITERATURE.

By W. Frank Fowler, M. D.,
Rochester, N. Y.

How often we congratulate ourselves upon thoughts supposedly our own, until a rereading of some nearly forgotten article discloses the source of our impressions. Of such unoriginal ideas this paper is largely composed.

The excellence of surgical papers appearing in the better journals has been increasingly apparent during the past few years. This improvement may be ascribed, in part, at least, to the example of a few truly literary surgeons who set the pace, to a more critical editorial attitude toward submitted manuscripts, and to several recent papers dealing with the subject of medical literature *per se*.

The recent transition from mere statements of facts, theories, and statistics to a narrative style of case reports has no doubt also contributed to an increased interest in medical English. There could be slight incentive to literary effort when the style of medical writing resembled newspaper market quotations. It is probable, too, that a quickened literary conscience is merely a natural part of the general medical uplift: an uplift evidenced by an accomplished standardization of colleges and a contemplated standardization of hospitals.

The journals, themselves, by virtue of superior paper, illustrations, type, and arrangement have attained general attractiveness and excellence. They encourage and demand worthy contributions. It is rather remarkable that the *Annals of Surgery* began publication as recently as 1885, and the first issue of *Surgery, Gynecology, and Obstetrics* did not appear until 1905.

Papers consisting of case reports and general discussions of personal experiences, together with those describing operative technic and experimental surgery appear most prominently. There is abundant evidence, also, of a renascence of surgical pathology for the surgeon, and the diagnostic value of the röntgen ray is given due recognition. Purely theoretical articles and papers dealing with subjects allied to general surgery are comparatively infrequent.

Papers consisting of case reports constitute an admirable method of written surgical teaching. Their worth has been noted by Seelig (1) and others. They have been inconspicuous in modern literature, however, until quite recently. The inherent value and interest of these reports lies in the fact that each one is a chapter from the book of experience. They readily lend themselves to pleasing methods of presentation and are therefore unusually readable and easily remembered.

For example, Lund (2) describes a series of cases of congenital cystic kidney. After considering the theories of etiology he quotes the classification of clinical history according to Milward as follows: 1. The stage of enlargement without subjective symptoms. The tumor may be discovered by accident. 2. The stage of subjective symptoms and objective signs, the signs and symptoms depending upon the size and weight of the tumor; and, 3, the stage of decreased elimination of urine.

He reminds us that both kidneys are usually involved, although one may be very large and the other not palpable; that the enlargement must be differentiated from that due to hydronephrosis or hypernephroma, but diagnosis may be impossible before operation; that the appearance of the cysts is quite characteristic, as they are multiple, are of varying sizes, with more or less functioning kidney tissue between them, and are yellow, green, red, and brown in color; that the function of the involved organs varies with wide limits; that the treatment consists in puncturing as many cysts as practicable (Rovsing operation) in the larger kidney with a view to arresting the disease and thus preventing further impairment of function; that the smaller kidney may be operated upon later, if necessary, and finally, although a cure may not be expected, it is usually possible to prolong life in comparative comfort for varying periods. The writer has summarized Lund's admirable article quite at length because he (the writer) believes that this type of paper is destined to fill an increasingly important place in surgical literature. It cannot, however, supplant other types of papers; each sort has its unique value.

In 1788, the Medical Society of New Haven County, Conn., published a small volume of *Cases and Observations*, containing, among other good papers, Hezekiah Beardsley's Case of a Schirrus in the Pylorus of an Infant (3). It is interesting to note in passing that the "schirrus" of Beardsley is probably the same condition recently discussed by Richter, Scudder, Downs, and others as hypertrophic stenosis of the pylorus. Beardsley's paper was written during the period when medical colleges were inefficient, and medical knowledge was gained principally from the preceptor at the bedside. Following the days of the preceptor, medical education was at a low ebb, the majority of medical colleges were still incompetent, there was no clinical teaching, and case reports appeared only sporadically in the literature.

The modern revival of clinical teaching is reflected in the literature by a return of case reports in the periodicals. We find ourselves consulting these reports more and more frequently for some point of information which may not be found in the textbooks at all, or, if there, is buried in unessentials. The bound journals, with their excellent indexes, constitute a valuable reference library of information, which is up to date, although somewhat limited in scope.

Returning to our analysis of the prevailing types of contributions, we notice a paper by Deaver (4) on gastric hemorrhage, which defines the significance of a symptom, and an article concerning the goitre question by Charles Mayo (5), which discusses the disease in its entirety. Papers by Schmidt (6) and Buford (7), the former relating to nephrectomy during pregnancy, the latter to the surgery of infants and small children, refer to particular classes of patients. An article by Carl Beck (8) concerning plastic operations on the stomach, and another by Horsley (9) on reversal of the circulation in the lower extremity, are typical contributions to the literature of experimental surgery.

Papers relating to technic, such as Porter's (10) description of his boiling water injection into the thyroid, and the contribution of Percy (11) concerning the effect of heat upon carcinoma of the cervix, involve new principles of treatment. The greater number of articles on operative technic, however, refer to the simplification of existing methods and are quite significant of the modern trend. Equally indicative of a present day tendency is the suggestion of Davis (12) that plastic surgery be made a specialty in every large surgical clinic. Davis quite properly reminds us that general surgeons as a rule do this work rather poorly.

Notwithstanding a pardonable pride in reporting brilliant successes, current writings show an admirable tendency toward honest analysis. Thus Beckman (13) reviews the postoperative complications (nonfatal) in a large series of cases, Connell (14) enumerates disappointing results from operations for chronic appendicitis, and Dickinson (15) reminds us that adhesions *do* ensue and death *does* follow operation. Such papers should serve as a check upon exuberant surgical enthusiasm.

Papers requiring drawings to supplement the text, particularly those describing technic, are splendidly illustrated, so well, in fact, that in many instances the text has become subordinated to the illustrations. The services of the few best known artists who specialize in this branch of art are not available for the majority. Nevertheless, the writer has learned from personal experience that the expenditure of a little patience in explaining what is required by means of rough sketches, illustrations from journals, and a few anatomy lessons will enable a capable commercial artist satisfactorily to interpret our ideas. Photographs of operative procedures are apt to be unsatisfactory. The camera will not always make prominent the part which should be emphasized. Blood stains and shiny lights on wet tissues detract from the general effect. Even a retouched photograph is inferior to a good drawing.

According to Garrison, the investigations of Sudhoff show that "up to the time of Vesalius, anatomical and other illustrations were for centuries based upon servile tradition and almost devoid of any signs of original observation." In another place Garrison states that "there were plenty of dissectors and dissections before Vesalius, but he alone made anatomy what it is today—a living, working science." The correlation of medical illustration and medical teaching is obvious.

The same tendency toward case reports and suitable illustrations, which is such a pleasing feature of the periodicals, is apparent also in a lesser, but happily increasing degree in recent textbooks. Seelig (16) says, "The value of adequate illustrations cannot be overestimated. Kelley's *Operative Gynecology* with Broedel's masterly pictures, in 1899, marked a new era and revolutionized the art of medical illustration both in this country and abroad." Few textbooks even today, however, contain such a comprehensive and well illustrated description of an operation as that given by Guthrie (17) of the Rodman breast amputation.

Textbooks of former years have fallen far short of their mission. They have consisted, chiefly, of a formal recital of facts and theories, uninteresting and insufficiently informative. The usual stereotyped lists of symptoms are very misleading, particularly to the young surgeon who has not yet gained the perspective of experience. He is at a loss whether to believe the patient or the textbook.

The didactic and the statistical have an undoubted value and cannot be entirely eliminated, as Seelig (18) reminds us. Nevertheless clinical teaching by means of case reports, notably the work of Cabot (19), is demonstrating its unique worth and is proving that textbooks need not be dry as dust. It is rather significant that Mall, of Johns Hopkins, has entirely done away with didactic, descriptive lectures in anatomy and isolates his student dissectors in separate rooms.

The ideal textbook would consist, as far as possible, of a series of monographic compilations of case reports, with conclusions and full bibliography. Each monograph should be written by a surgeon who is particularly qualified for abstract work and enthusiastically interested in his subject. The writer believes that abstracts of American papers, at least, should be made by the compiler himself. He should have complete knowledge. There will be no difficulty, ordinarily, in obtaining single copies of American journals from the publishers.

As regards style, we should be content to express ourselves simply, with familiar words and in our accustomed manner. Graceful phrases had best be left to those who are skilled in their use. We admire the art of Oliver Wendall Holmes, but we do not emulate it.

McCrae (20) deprecates the prevalent careless use of such medical words as "rheumatism," "asthma," and "biliousness." He cites the patient who told his physician that several doctors had made a diagnosis of rheumatism, but examination (he had never before been examined) revealed a popliteal aneurysm. It is evident, as McCrae states, that a hazy conception of medical terminology is often responsible for incorrect diagnosis. It is also apparent, as in the differentiation between acute osteomyelitis and rheumatism, that such a mistake might be disastrous. McCrae's article and the *Suggestions for Writers of Medical Papers,* by Mrs. Mellish (21), could be read profitably by all of us. Finally, it seems fitting to quote some one who warns us to "say what we have to say and stop."

The writer acknowledges his indebtedness to Dr. F. F. Dow for valued suggestions.

DO YOU KNOW THAT?

BY A. L. BENEDICT, M. D.,
Buffalo,
Consultant, Digestive Diseases, Columbus Hospital; Attendant, Mercy Hospital.

Before the promulgators of this kind of literature are placed in the same class of extrahazardous risks as the men who ask, Is this hot enough for you?—the writer would like to perpetrate a little himself.

Do you know that a gain in weight in a series of cases has been alleged for nearly every discarded system of treating tuberculosis?

Do you know that a healthy man cannot assimilate the amount of codliver oil and other fats often prescribed for tuberculous patients?

Do you know that warm air can be as pure as cold?

Do you know that a window open an inch, with the wind blowing thirty miles an hour and with the outdoor temperature 20 or 30° F. below the initial indoor temperature, will renew the air in a bedroom more quickly than a wide open window on a hot still summer night?

Do you know that a sleeping porch or verandah, inclosed in winter and provided with a gas stove, may contain more impure air than a well heated and ventilated living room?

Do you know that the average healthy physician, compelled to sleep on a cot in a tent, during a snow or rain storm, will forget all about the pneumococcus and insist that he is going to have pneumonia?

Do you know that a cleanly consumptive occasionally sneezes and coughs? Do you know how he is going to prevent the dissemination of bacilli in the resulting spray?

Do you know just what natural factors in disinfection render it possible for us to assure a recalcitrant community of ignorant persons, that a hundred tuberculous patients in an institution in the midst of them absolutely cannot infect their air or water?

Do you know that the same kind of foolishness that a phthisiophobe exhibits is what keeps a great many persons from being run down by locomotives and automobiles?

Do you know that, to insure sufficiently early operation in cancer of internal organs, the surgeon must be called before anything more than a guess as to diagnosis is made?

Do you know that, even then, twenty-five per cent. of cures is almost the highest announced under the most favorable circumstances?—and that ten per cent. is about the best actual achievement?

Do you know that, after the age of fifty years, absence of hydrochloric acid occurs in many more benign than malignant cases?

Do you know that very few cases in which hyperchlorhydria is demonstrated, are of ulcer, and that very few cases in which ulcer is demonstrated go on to cancer of the stomach?

Do you know that about all the positive advice we can give to prevent the development of cancer is: 1. Do not keep picking at a wart or mole, but have it removed; 2, do not allow any source of continually repeated mechanical irritation to remain; 3, do not take up x ray or radium work; 4, do not bear children; 5, do not live more than forty years.

Do you know that it may be impossible to diagnose cancer positively and still be possible to state positively that, if the condition is cancer, it has progressed too far for a radical operation?

Do you know that the rural death rate is higher and the rural birth rate lower than the urban, at least for New York State?

Do you know that a law closing all public restaurants would compel every man to set up housekeeping or starve? You don't? Then why do you think the same kind of legislation would settle the alcohol and social evils?

Do you know that the purity of the little boy is just as precious as that of the little girl? If you do, exert your influence to make the law recognize the fact. If you do not think so, explain how one can be preserved and the other neglected.

Do you know that a house of prostitution, however quiet and even limited to one inmate, would be as objectionable in the immediate neighborhood of your home as a moving picture show? Then do not denounce segregation too strongly.

A CASE OF LEPROSY IN CONNECTICUT.

By John E. Lane, M. D.,
New Haven.

Leprosy is very rarely seen in this part of the United States, and as far as I have been able to determine, only one other case has been seen in Connecticut in recent years. It is for this reason that the following case is briefly reported.

On November 20, 1916, T., aged twenty years, presented himself at the dermatological clinic of Yale University. A detailed description of the findings is needless, as he showed the usual features of a well developed though not severe case of the nodular type of leprosy: Nodules, dirty brownish gray pigmentation, areas of anesthesia, analgesia, and hyperalgesia, general glandular enlargement, and thickening of some of the nerve trunks.

Although the diagnosis was made at first sight, and though it would be unmistakable to anyone familiar with leprosy, it was thought best, in view of possible complications in the future handling of the case, to confirm the diagnosis by laboratory methods. Dr. C. J. Bartlett, professor of pathology in Yale University, School of Medicine, kindly made the examinations for me.

The Wassermann reaction, as is usual in these cases, was strongly positive. Leprosy bacilli were easily demonstrated in smears of the nasal secretion. Sections of an excised nodule were filled with masses of the bacilli.

The chief interest in this case is the illustration of the fact that leprosy patients wander about for a long time without being recognized, as a majority of the physicians have never seen a case of the disease, and quite naturally do not suspect it.

This patient was living in a nearby town, where he had been for six weeks. He was a Greek, born in Thessaly, and he came to New York in 1912. Since that time he has lived in different places in New York, in Pennsylvania, in West Virginia, and in three or four towns in Connecticut.

THE LATE DR. PETER BRYNBERG PORTER.*

By Reynold Webb Wilcox, M. D., D. C. L.,
New York.

Doctor Porter was the son of Peter Brynberg Porter of the old Delaware family who married Ann, daughter of Peter Brynberg, whose ancestors immigrated from Sweden in 1638. His mother was Elizabeth Deacon, daughter of Thomas Canby Alrich, a descendant of Jacob Alrich, the first Governor of Delaware, the progenitor of the family, and an immigrant from Holland in 1655.

He received his preliminary education at the Hyatt Military School, graduated as Bachelor of Arts at Yale College in 1867, received his Master of Arts in due course, and was a member of Phi Beta Kappa. He graduated as Doctor of Medicine at the University of Pennsylvania in 1869, and for two years served in the Philadelphia Hospital. Some years thereafter, he spent a long time in Europe, especially in Italy, and as a result became deeply and intelligently interested in the arts.

In 1871 he came to New York city, where he was engaged in the practice of medicine until his death on August 6, 1915, in his seventy-first year. He was for a time physician to the department of Diseases of Children at the Demilt Dispensary and to the New York Infant Asylum. He was for many years the New York correspondent of the *Boston Medical and Surgical Journal*, and since 1913 was an assistant editor of the New York Medical Journal.

He was one of the incorporators of the Medical Association of the Greater City of New York, in 1899, and was its recording secretary and editor of its Year Books, sixteen volumes, until his death. In these capacities his extensive knowledge of medical literature and accurate appreciation of its practical value, and his large acquaintance with professional men and the work which they were doing, resulted in the upbuilding of a large and influential scientific society, whose programs commanded full and appreciative audiences. Since its inception in 1900 he was the editor of the *Transactions* of the American Therapeutic Society. He was also assistant secretary of the American College of Physicians and of the American Congress on Internal Medicine from their foundation, and a member of the New York Academy of Medicine.

He was a member of the Sons of the American Revolution, and from time to time a contributor to patriotic literature, occasionally in verse.

He was a welcome guest in many of the homes of old New York families, where his broad education and courteous manners endeared him to a large circle of friends.

He was always essentially a student, critical, yet broad and constructive. He was of gentle disposition, charitable in thought and habit, yet ever maintained a high standard in all the associations of life. To those who knew and loved him he was a fine type of medical gentleman.

*Read at the seventeenth annual meeting of the American Therapeutic Society, Detroit, Mich., June 6, 1916. The Journal's tribute to Dr. Porter's memory appeared in our issue for August 14 1915.

Health Affairs in New Mexico.—New Mexico is burdened with a law conferring upon the State Board of Medical Examiners the duties of a State Board of Health, without making provision for funds to carry on the work. Its duties consist mainly in licensing applicants to practise medicine, the qualifications of whom need only be mediocre. The law provides that the various county officers shall act under the orders of the State Board of Health in carrying out its regulations. Owing to lack of funds the State Board of Medical Examiners, in its capacity of State Board of Health, must see its functions usurped by the county commissioners. Thus, according to the *Lancet-Clinic* for November 11, 1916, a divided responsibility and a conflict of authority exist both pathetic and amusing. In the meantime, the public schools of the State have no proper sanitary supervision; there is no pretense of medical inspection of school children; and drinking water, especially in many of the rural districts, is obtained from questionable sources. As for vital statistics, "there aint no such animal!"

Food and Food Preparation, in Health and Disease

FOOD AND EFFICIENCY.

By Martha Tracy, M. D.,
Philadelphia.
Professor of Physiological Chemistry, Woman's Medical College, Pennsylvania.

(*Continued from page 1151.*)

VI.

VITAMINE AND INORGANIC SALT REQUIREMENTS.

A quantitative statement of the daily vitamine and inorganic salt requirements of the body can be made with far less assurance than is the case in regard to the total fuel and protein food requirement. The chemistry of the vitamines, as previously stated, is still so vague that no definite measurement of the intake and output of these substances is possible. Experimentation and clinical observation, however, have given abundant proof that very small amounts of these mysterious compounds are sufficient to provide the essential stimulus, or supply the needed material without which the vital reactions cannot proceed.

Vegetable foods furnish the chief sources of these materials, especially the husks and cortical layers of cereals, and the juices of fruits. The potato is one of the vegetables which will most successfully supply to the body this vital need. Fresh meat and milk are also useful, but occasionally the milk of a particular animal has been found lacking in this regard.

Vitamines are variously affected by cooking and preserving processes, some being more thermostable or heat resistant than others, but it is a safe generalization that all are rendered in some degree less useful to the body by a high temperature, certain foods losing entirely their vitamine value by such treatment. The boiling of milk, therefore, the sterilizing to which canned foods are subjected, and the drying and smoking of meat, are all procedures which detract from the value of these foods by robbing them of their vitamine content. Excessive milling of cereals, also, such as is demanded by our craze for pure white flour and white polished rice, by stripping the grains of the cortical layer really renders these foodstuffs of inferior value to the body. A ration containing whole wheat and other unmilled grain products, some fresh food, with raw or lightly cooked vegetables such as lettuce and celery, and fresh fruit and fruit juices, will meet the vitamine requirement without other specific attention to this food requisite.

In our discussion of food requirement thus far, we have dealt with proteins as *nitrogenous* substances, and have laid stress upon the essential presence of this nitrogen in the food which is to serve for construction of nitrogenous or protein tissue. The proteins, as previously noted, however, also contain sulphur and phosphorus and, sometimes, iron and iodine. To build such tissue proteins these elements must be provided and are usually so provided in the protein of the food. Their requirement is, comparatively speaking, very small, and as to sulphur we need take no special thought to supply this element if we keep our protein ration adequate. This will provide about one gram of sulphur a day, which appears to be sufficient to meet the needs of tissue repair and to keep the body in a condition of sulphur equilibrium.

Phosphorus is needed in the body, not only to build into the protein of all the cells, but also in the construction of special phosphorized fats, or phosphatides, which are conspicuous as essential constituents of nerve tissue. In addition phosphorus must be supplied to provide the inorganic or mineral phosphates, chiefly of calcium, which give rigidity to the bones and teeth, and also to furnish the mineral phosphates of the blood. We find that some of this phosphorus supply must come to the body in previously constructed organic compounds, in the form of phosphorus-containing proteins such as casein of milk, and vitellin of egg yolk, etc., or in the form of simpler organic molecules called phytates, which are present in the husks and cortical layers of grains. If the greater part of the phosphorus requirement is thus met by the use of the food materials mentioned, the body can and does, for the completion of its daily need, avail itself of inorganic phosphates, such as are found in meat (muscle tissue containing acid potassium phosphate), in the whey of milk, and in fruit and vegetable juices.

In all, from 0.9 to 1.5 gram of phosphorus a day is necessary for normal metabolic processes. From a study of statistical dietaries of American families there is thought to be suggestive evidence of a tendency to deficient phosphorus food supply, and there is a growing appreciation of the fact that some of the nutritional disturbances difficult of recognition and, heretofore, of control, may in all probability result from a disturbed or inadequate phosphorus metabolism. It is interesting to note that, while cow's milk has a higher *total phosphorus* content than has human milk, the *organic phosphorus* is about the same in both. When, therefore, we dilute cow's milk in "modifying" it for infant feeding, in order to bring the protein and total salt content down to that of human milk, we are diluting also, with the fat and sugar, the organic phosphorus-containing compounds. We replace the fat and sugar by adding cream and lactose, but we do not as a rule remember to restore the organic phosphorus, and we may have here a clue to the failure of modified cow's milk with certain infants.

The element iron is an essential part of the characteristic protein, hemoglobin, which is the chief constituent of the red blood corpuscles, giving the color to these cells. Iron is also present in the nuclei of all cells, and so must be considered of fundamental importance in relation to cell multiplication and reproduction, a function residing in this part of the cell. About three grams of iron are believed to be present in the entire adult body, and as nearly as can be estimated about fifteen mgms. of iron a day

will furnish an adequate supply for the maintenance of iron equilibrium. This iron must be supplied in organic form, in egg yolk, in the hemoglobin or its derivatives retained in red meats, and in vegetable organic compounds such as are relatively abundant in spinach, oatmeal, entire wheat flour, in breakfast foods, in peas, beans, raisins, and prunes. Iron in inorganic form, such as is frequently given medicinally, appears to serve only as a stimulant to the production of hemoglobin from the materials in iron-containing foods, but is probably not itself used in tissue construction.

The chief iodine-containing tissue of the body is the thyroid gland and its secretion, and our knowledge of the iodine food supply is excedingly vague. In certain geographical areas of the earth there occurs deficient development of this gland, and no food substance has been found to remedy this deficiency. In such cases the feeding with the dried thyroid tissue of another and normal animal provides the only recognized means of supplying the lacking material.

Calcium is a mineral substance of great importance for the building of bones and teeth (calcium phosphate and calcium carbonate), and as a constituent of the salts of the blood and lymph. Ninety-nine plus per cent. of calcium is in the bones, but the remaining fraction of one per cent. occurring in the body fluids is of vast importance in relation to the irritability and contractility of muscle tissue; the proper balance between contraction and relaxation of the heart muscle, for example, being related to the proper proportions of calcium, sodium, and potassium salts. According to Meltzer, "calcium is capable of correcting the disturbances of the inorganic equilibrium in the animal body whatever the directions of the deviations from the normal may be. In any abnormal effect which sodium, potassium, or magnesium may produce, whether the abnormality be in the direction of increased irritability or of decreased irritability, calcium is capable of reestablishing the normal equilibrium."

The amount of calcium necessary in the food to maintain in the body a normal supply of this element is not yet determined with definiteness. It appears that the equivalent of about 0.7 gram of calcium oxide a day will maintain calcium equilibrium in a normal man. In childhood, where construction of bone is going on, a greater amount of calcium is obviously necessary. Here, as with phosphorus, American dietaries show a tendency to deficiency in calcium-containing foods, and the infant changing at weaning from a milk diet with abundant calcium, 0.17 per cent. calculated as calcium oxide, to a diet of bread and meat containing respectively 0.06 per cent. and 0.01 per cent., is liable to suffer from lack of sufficient calcium for bone construction. Eggs and green vegetables contain a higher percentage of calcium salts, but the free use of milk is perhaps the simplest and most effective way of meeting the calcium requirement in children.

In sodium chloride, common salt, are two elements, sodium and chlorine, which are indispensable constituents of the body fluids. The chlorine is an essential element in the hydrochloric acid of the gastric juice, and the sodium chloride itself is present in the blood and lymph plasma. On a meat diet sufficient sodium chloride is coincidently ingested in the retained blood salts of this animal tissue. In a vegetable diet, however, this salt is not naturally present, and by reactions within the body some of the normal chloride supply may be led to form substances which are excreted, and the need of more chlorine may arise. Thus vegetarian animals, as well as man on a similar diet, crave salt as a necessary food constituent.

Potassium and magnesium are elements that are found in the form of salts in the fluid and solid tissues of the body, and are received incidentally in the food supply, chiefly as potassium and magnesium phosphates.

Of these mineral substances sodium chloride is the only one likely to be taken in deleterious quantity, and those who add salt in unnecessarily large amounts to every food would do well to curb this perverted appetite and avoid the constant strain and burden of excretion of this substance which mere habit thus places upon the kidneys.

We have elsewhere referred, however, to the fact that excess of protein will tend to yield acids in the body, such acids being the result of oxidation of the phosphorus and sulphur contained therein. The neutralization of such acids will require reaction with them of the base forming elements, sodium, potassium, and calcium, which may thus be withdrawn from other needful duties in the body economy. The limitation of the protein intake is therefore also to be recommended from this point of view of avoiding excess of acid forming foods.

VII.

BULK REQUIRED IN FOOD STUFFS.

Having thus established with a considerable degree of scientific precision just what materials, and how much of each, must, for efficiency's sake, be present in an average day's ration, is this the end of the story? The suggestion crops up from time to time that it would be convenient and time saving to prepare of these necessary foodstuffs, nicely purified and concentrated, neat little packages or pellets which could readily be carried in the pocket and swallowed at appropriate intervals, thus avoiding the annoyance and interruption of the day's work or pleasure for meals. Unfortunately for those to whom such a suggestion appeals, but fortunately for those of us who enjoy the pleasant relaxation of mealtimes and the taste of food, such a procedure proves to be entirely contrary to Nature's plan.

The food materials containing the necessary specified ingredients must undergo chemical changes in the gastrointestinal tract before they can be of use to the body, and for the accomplishment of such changes the digestive juices are necessary. These juices are secreted by the glands of the stomach and intestines under the influence of definite stimuli, and the agreeable taste of foods in the mouth furnishes a very important psychic stimulus to such so called appetite secretion. The wise physiologist, Voit, defines a food as a "palatable mixture of foodstuffs which is capable of maintaining the body in an equilibrium of substance." A food pellet washed down with a swallow of water would meet an unprepared gastric mucous membrane with no appetite juice ready to handle it promptly and properly.

The concentration of the food materials is also far from desirable. Food substances in more or less resistant and hard condition are of great advantage in providing needful exercise for the teeth and muscles of mastication. During the process of mastication the truly soluble and digestible parts of the food are separated from the coarse protecting fibres and husks, the taste buds are stimulated, and there is pleasure and satisfaction in the sensations produced. These coarser and indigestible parts of our ordinary food mixtures are also of value in giving bulk to the material ingested and thus furnish a mechanical stimulus to the muscular movements of the digestive tract. If these movements are not sufficiently active, there will be incomplete commingling of digestive juices with the food, chemical changes will be incomplete, absorption of the products of digestion will be hindered, putrefactions and fermentations due to bacteria will occur, and the residue of indigestible and undigested materials, with also such substances as are excreted from the blood into the intestinal canal, will not be moved along and properly removed from the body.

The essential food ingredients upon which we have laid such stress must, therefore, be presented to the body in such form as will taste good and create appetite, and must be intermingled with coarse and even indigestible substances whose presence is of advantage only as a matter of bulk. Condiments of various sorts are, in reasonable amounts, legitimate stimulants to the flow of digestive juices. The extractives or juices which give the agreeable flavor to meats and clear soups, are really no more than such appetizers, but are very desirable and useful from this point of view. On the other hand, the cellulose fibres of coarser vegetables, cabbage, turnip, spinach, etc., are of no value as appetizers, but are extremely useful as bulky foods, since they promote the peristaltic or muscular movements of the intestinal tract, and prevent constipation. Fruit juices are also important stimulants to peristalsis, and a glass or two of water taken with the meal will also promote chemical changes, absorptive function, and motor activity.

(To be concluded.)

The Treatment of Diabetes by Alimentary Rest.—O. Leyton, P. J. Cammidge, and John Hume (*Practitioner,* November, 1916) contribute three papers to this subject in which much attention is paid to the details of the diet. Leyton's procedure is as follows: For two days the patient is placed upon a diet poor in fats, e. g., for breakfast, two eggs and some special bread poor in carbohydrates, with a spoonful of marmalade made without sugar, a cup of weak tea with a little milk. For lunch, three ounces of lean meat, six ounces of cooked cabbage, two ounces of boiled potatoes, and a small baked custard pudding. For supper, a cup of tea with a little milk and a diabetic biscuit. For dinner, a plateful of clear soup, four ounces of fish other than salmon, herring, or mackerel, four ounces of cooked green vegetables, an egg, and an orange. After the second day the patient remains in bed and takes a Seidlitz powder on an empty stomach in the morning. If this does not act satisfactorily, an enema must be given. During the period of alimentary rest the meals are: Breakfast, three ounces of clear broth and six ounces of weak coffee without milk or sugar. Lunch is exactly similar. Supper, six ounces of weak tea without milk or sugar. Dinner, similar to breakfast with perhaps six ounces of weak tea instead of coffee. It is essential that each article of food be prepared as directed, and to have the fluids given in cups that hold no more than the prescribed quantity. Weak coffee is made by pouring ten ounces of boiling water on one or two heaped teaspoonfuls of freshly ground coffee in a jug that has been heated, allowing it to stand five minutes, and then straining. Weak tea is made by pouring ten ounces of boiling water upon one heaped teaspoonful of tea and allowing it to stand for three minutes. Clear broth is made by adding an eggspoonful of meat extract that is not rich in protein to three ounces of boiling water. A vegetable is to be boiled in at least four times its weight of water: after it is fully cooked it is to be freed from water and weighed, then stewed for a quarter of an hour in a little clear broth and flavored with pepper and salt to taste. When it is to be cooked in several changes of water, two saucepans are necessary; when it is partly cooked in one it is to be transferred to the boiling water in the other. Cabbage boiled in three waters may replace French beans in the following dietary, which is started when the urine is free from sugar:

First day. Seidlitz powder. Breakfast: Six ounces of weak coffee without milk or sugar; three ounces of cooked French beans. Lunch: Six ounces of weak coffee without milk or sugar; four ounces of cooked French beans. Supper: Six ounces of weak tea without milk or sugar. Dinner: Six ounces of weak tea without milk or sugar; three ounces of cooked French beans. Carbohydrates, six grams; protein, three grams; fat, four grams; calories, 72.

Second day. Seidlitz powder. Breakfast: Six ounces of weak coffee without milk or sugar; seven ounces of cooked French beans; one boiled egg. Lunch: Seven ounces of cooked French beans; one boiled egg. Supper: Six ounces weak tea without milk or sugar. Dinner: Seven ounces of cooked French beans; one boiled egg. Carbohydrates 11, protein 23, fat 22, calories 334.

Third day. Seidlitz powder. Breakfast: Six ounces of weak coffee with one teaspoonful of cream; one boiled egg; seven ounces of raw lettuce. Lunch: One egg; seven ounces of cooked cucumber. Supper: Six ounces weak tea with one teaspoonful of cream. Dinner: Seven ounces of cooked French beans; one egg. Carbohydrate 16, protein 24, fat 21, calories 349.

Fourth day. Seidlitz powder. Breakfast: Six ounces weak coffee with a teaspoonful of cream; one boiled egg; seven ounces of raw lettuce. Lunch: Seven ounces of cooked cabbage; one egg. Supper: Six ounces of weak tea with a teaspoonful of cream, no sugar. Dinner: Seven ounces of cooked French beans; one egg. Carbohydrate 21, protein 25, fat 21, calories 373.

Fifth day. Seidlitz powder. Breakfast: Six

ounces weak coffee with a teaspoonful of cream; one egg; seven ounces raw lettuce. Lunch: One ounce cooked lean meat; seven ounces cooked cabbage. Supper: Six ounces weak tea with a teaspoonful of cream, no sugar; one egg. Dinner: Eight ounces clear soup; one egg; seven ounces cooked French beans. Carbohydrate 21, protein 38, fat 23, calories 442.

Sixth day. Breakfast: Six ounces weak coffee with one teaspoonful of cream, no sugar; one egg; seven ounces raw lettuce. Lunch: Three ounces cooked lean meat; four ounces boiled French beans; one and a half ounce boiled potatoes. Supper: Six ounces weak tea with one teaspoonful of cream, no sugar; one egg. Dinner: Three ounces of cooked French beans; three ounces of cooked cabbage; one egg. Carbohydrate 25, protein 50, fat 29, calories 561.

Seventh day is a fast day. Seidlitz powder first thing in the morning. Breakfast: Three ounces clear soup; six ounces weak coffee without milk or sugar. Lunch: Three ounces clear soup; six ounces weak coffee without milk or sugar. Supper: Six ounces weak tea without milk or sugar. Dinner: Three ounces clear soup; six ounces weak tea without milk or sugar.

Eighth day. Breakfast: Six ounces weak coffee with one teaspoonful of cream; one egg; one ounce of cooked fat bacon; seven ounces of raw lettuce. Lunch: Two ounces of cooked lean meat; four ounces cooked French beans; one and a half ounce boiled potatoes. Supper: Six ounces weak tea with one teaspoonful of cream, no sugar; one egg. Dinner: Eight ounces clear soup; one egg; three ounces cooked cabbage; three ounces cooked French beans. Carbohydrate 25, protein 51, fat 41, calories 673.

Ninth day. Breakfast: Six ounces weak coffee with one teaspoonful of cream, no sugar; one egg; two ounces cooked fat bacon; seven ounces raw lettuce. Lunch: One and a half ounces cooked lean meat; four ounces cooked French beans; two ounces boiled potatoes. Supper: Six ounces weak tea with one teaspoonful of cream, no sugar; one boiled egg. Dinner: Ten ounces clear soup; one egg; three ounces cooked French beans; three ounces cooked cabbage. Carbohydrate 28, protein 54, fat 54, Calories 814.

Tenth day, same as the ninth, except for the addition of an ounce of butter to the vegetables. Calories 1,039.

Eleventh day. Breakfast: Six ounces weak coffee with one teaspoonful of milk, no sugar; one egg; two ounces cooked fat bacon; seven ounces raw lettuce. Lunch: One and a half ounces cooked lean meat; four ounces cooked French beans; one ounce boiled potatoes; one half ounce butter. Supper: One half ounce white bread; six ounces tea with one teaspoonful of milk or cream; one half ounce of butter; one egg. Dinner: Eight ounces clear soup; one egg; three ounces cooked cabbage; three ounces cooked French beans; one half ounce butter. Carbohydrate 31, protein 54, fat 90, calories 1,150.

Twelfth day, same as the eleventh, with the addition of one ounce of butter. Calories 1,375.

Thirteenth day. To the diet of the eleventh day add two ounces of butter and half an ounce of white bread, taking care to spread the carbohydrates equally over the four meals. Not more than a half ounce of bread at each meal. Calories 1,660.

The fourteenth is a fast day, with a diet in every respect similar to that of the seventh day.

Fifteenth day similar to the thirteenth. From this time on the increase in the diet should consist of one ounce of boiled potato on alternate days, or, if the patient prefers, a quarter ounce of bread may be added on alternate days instead. A further increase of one ounce of butter or fat should be made on the twentieth day. The twenty-first day should be one with a modified diet. Bread and potatoes should be withheld.

When sugar reappears in the urine, the patient must fast until it disappears again; usually thirty-six hours suffice. The carbohydrate is then reduced to one half of that which was in the diet, and then increased very slowly five grams a week until the sugar appears again. The second limit must be recognized as the amount which is too much for the patient, and not more than three quarters should be given in the food for several months. Many diabetics manifest glycosuria on being given an excess of protein; then the limit must be found and the diet arranged so that not more than three quarters of the amount is given.

Both Leyton and Cammidge give tables showing the protein and fat content of various foods, which are much too long to reproduce here. The dietary Hume allows after the sugar has disappeared from the urine differs considerably from the one just quoted from Leyton, and does not seem so exacting, but the urine should be examined after each meal. He gives for breakfast two ounces of oatmeal well boiled and taken with cream; three ounces of smoked bacon and one whipped egg fried; tea with a little cream, and saccharin if desired as a sweetening agent; eight ounces of fresh white fish may be substituted for the bacon. Midforenoon: A glass of equal parts of cream and warm water, or one glass of warm lemon juice to which one teaspoonful of glycerin has been added. Dinner: Six ounces of roast meat, with green vegetables and the centres of boiled potatoes; custard unsweetened, flavored with lemon or vanilla, and taken with cream if desired. As a third course Gorgonzola cheese with lettuce is suitable. Soup and eight ounces of white fish served with butter may occasionally be taken in place of the roast meat. Supper: A glass of lemon juice or diluted cream or tea with saccharin may be taken. Six ounces of fish, or three ounces of butcher meat with vegetables or tomato; fish may be taken if roast meat was served with dinner. Soda water or beer is a suitable drink for the evening meal. The patient should be instructed to take only very limited quantities of bread. If sugar reappears, a fast is arranged. If this is caused by the protein, it may be necessary to restrict the whole diet. He has not found it necessary to estimate the the value of the food consumed in heat units, or to go into minutiæ of analyses, details which are difficult to obtain accurately in a hospital, let alone in private practice.

NEW YORK, SATURDAY, DECEMBER 23, 1916.

THE DIAGNOSIS OF SCURVY IN INFANTS.

The fact that a child is fat is generally accepted as an evidence that it is in good health. It not infrequently happens, however, that infants who are fed artificially gain in weight and present a plump appearance, although they suffer from scurvy or other diseases caused by errors in diet. A distinguished orthopedic surgeon of New York recently stated that hardly a week went by without having an infant brought to his attention on suspicion of some skeletal fault which on examination turned out to be a victim of infantile scurvy. This has occurred so frequently that this particular surgeon has come to be quite an expert in the diagnosis of this disease.

While some of these cases are brought to the orthopedist by laymen, many are sent by physicians who would undoubtedly be able to make a correct diagnosis had their suspicions once been aroused as to the real nature of the disease. Scurvy in infants is characterized by marked prostration, anemia, and general debility. The child is apt to lie with the legs drawn up and immobile and any attempt to move the legs causes pain. Later the limbs become tender to the touch or everted and immobile, a condition of pseudoparalysis which, in the presence of an epidemic, might easily mislead the observer into pronouncing the case one of poliomyelitis. The later symptoms, including epiphyseal fractures, thickening of the bones, prolapse of the eyeball, puffiness of the upper lid, and subconjunctival ecchymoses, are so characteristic that they are not likely to be overlooked. It is in the earlier stages that the mistake in diagnosis is apt to occur, and here an inquiry into the diet of the infant will generally furnish a clue. Fortunately, infantile scurvy is not only diagnosed with ease and certainty, but it readily yields to orange juice, lime juice, and other recognized antiscorbutic agents.

THE GOLDEN AGE.

While we may fancy our present time one of most extraordinary advance in medical science, the golden age—the age which marked the most Brobdignagian steps in scientific discovery, making possible the progress of our present period—was the seventeenth century. In this year of the celebration of the tercentennial of the death of Shakespeare it is appropriate to call attention to the fact that many of the greatest minds in science arose, chiefly in the same country, and contemporaneous with, or just following the time of the great dramatist. It piques our curiosity to know what conditions produced, in such short sequence, so many great thinkers.

William Harvey stands foremost among the great men of this age, and his idea of the circulation of the blood was probably first presented in 1615 or 1616, though his book on *The Motions of the Heart and Blood in Animals* was not published until 1628.

The discovery of the movement of the blood through the capillaries, which Harvey saw only in imagination, was delayed until the invention of the compound microscope. The capillary circulation was first seen in the capillaries of the lungs by Malpighi, in 1668, while Leeuwenhoek, the Dutch scientist, in 1686, studied the general capillary circulation in the tail of the tadpole. The same man first described accurately the red corpuscles. He also investigated the structure of the teeth and of muscle and, last but not least, discovered bacteria in the tartar of the teeth. Willis, who described the circulation of the brain, and named the cranial nerves, belongs to the same century. The transfusion of blood in both animals and human beings is also noteworthy of this age.

The foundations of the physiology of respira-

tion were laid by the versatile Robert Hook, who, in 1667, showed before the Royal Society a dog, without its ribs and diaphragm, which he kept alive by blowing air into the lungs by means of a bellows. He first pointed out that "a sufficient supply of fresh air" is necessary to life, and that the lungs have other functions than the cooling of the body. Hook also discovered and named the cell, and made many other contributions to science. John Mayow (1674) practically discovered that it was oxygen, though he gave it another name, which, in air, is essential for animal respiration, and that it was taken into the blood. The work of Robert Boyle, who worked in conjunction with Hook, helped to forward the study of the respiratory function.

Names of great men of this period might be multiplied, but we will add here only one other, that of Regnier de Graff, of Holland, who in 1677 was probably the first to obtain the digestive juices by means of artificial fistulæ. He made valuable studies of the ovary under various conditions, and his name has rightly become connected with the follicle.

Not only had the age its great investigators, but it was golden in its product in scientific reflection, for there stands out no less a figure than that of Sir Thomas Browne, whose *Religio Medici* has not been surpassed among medical writings for ingenuity and depth of thought, or for quaintness and vigor of style.

IS PROSPERITY SHORTENING OUR LIVES?

At the tenth annual convention of the Association of Life Insurance Presidents, held in New York recently, many and solemn were the warnings issued to the "pink, plump, smooth, and healthy looking American, hurrying, nevertheless, to his grave at forty years." The milk in the cocoanut appeared in the peroration of one of the speakers, who said: "The prosperity of our patrons necessarily interests us for with extravagance comes poverty and increases in policy borrowings and cash surrenders, and the loss of insurance protection to numberless families." Another orator, ignorant or heedless of how presbyopia descends upon the just and the unjust, attributed the frequent eyeglasses to strain by "close focus and inside work." A third speaker mitigated somewhat the alarming language of his predecessors by stating that the people of the United States carried more life insurance than all the other inhabitants of the earth put together.

There was a time doubtless when our countrymen put more money into insurance than they do now, because they did not find it easy to put it anywhere else. With the development of the savings bank, and especially of the postal bank, vast sums are diverted in their direction. Men, too, like to enjoy the fruits of their investments, and to accomplish that through insurance, they are obliged to take out the very costly endowment policies. Then perhaps they have not yet forgotten the merry investigation of the insurance companies by former Governor Hughes, and believe that too much of their money was expended on junketing, on violets for horses, and on entertainments for actresses. They are persuaded that the companies could be still more economical than they have learned to be; that they might shave perhaps another dollar off the doctor's examination fee. Ought not a doctor to examine candidates for insurance gratis? The public are an ungrateful lot, at best, and the more the companies do for them, the less thanks they will receive; particularly when the public observes the rather obvious prosperity of all officers of insurance companies. Still, if investment in insurance grows at the rate of one billion a year, what must have been the growth in times past, at which the officers gaze so longingly?

PHYSIOLOGY OF THE EIGHT HOUR DAY.

So important a matter as the proper length of the working day should by no means be left solely to the dictation of sentiments of social reform, economic improvement, or political exigency. If there is any rational basis for a proper working day, it must of necessity rest fundamentally on physiological grounds. Such is the argument ably and soundly defended by Frederic S. Lee (*Science*, November 24, 1916, p. 727).

Tracing the development of the eight hour working day, Lee finds that it has been fostered by a variety of motives, some good and some bad, but that the movement is sound and rational only so far as there are physiological grounds for it. Such grounds do exist. It takes no details of laboratory study to show the actual evil effects of a working day of fifteen hours, especially on women or children, and such conditions are disappearing. But there is abundant testimony of indubitable authority, specimens of which are cited by Lee, showing that the decrease of the working time from twelve to ten, from ten to nine, and finally from nine to eight hours, was in each case accompanied by a decided increase of output. Each change gave a definite and often quite extensive improvement in both quality and quantity of work done. The data on which these statements rest are too voluminous to quote but are available for the student.

Lee notes that the logical determination of the

proper working day, since it rests finally on physiological grounds, cannot be made by legislation, nor can a hard and fast rule be established to which all workers must conform. The elements which make up fatigue are numerous and are psychical as well as physical. Occupations characterized by much muscular exertion, unusually quick or complex muscular action, often repeated monotonous single acts, constant strain of body or attention, and those carried on in crowded or unhygienic quarters, according to Lee predispose to a fatigue which may easily run over into exhaustion. He believes that more exact studies are needed on these fatigue factors in occupation, and also of the individual variations of susceptibility to fatigue. Because of the absence of trustworthy data on these points, it is hard to say absolutely that an eight hour working day is a physiological necessity. Professor Abbe, of Jena, is quoted as believing the eight hour day the ideal, and worthy of being sought by all industries. Such a conclusion is a temporary makeshift, however, and only postpones the real problem.

One paragraph in Lee's article should be quoted in full: "By so much as a man rises above this stage (of being employed by others), he becomes free to choose his own working time. It is a noteworthy fact that with the world's leaders, in industry, in finance, in professional life, the duration of the daily task is wholly secondary to its accomplishment. They are limited by no eight hour, ten hour, or twelve hour considerations. This indicates why such men become leaders. Laborers may learn a valuable lesson from this fact. The greedy employer who constantly saps the energies of those who are the medium by which he gains his wealth, is to be condemned no more than is the 'slacker' whose only guiding principles are a minimum of effort and a maximum of wage. Moreover, it is trite to say that the obligation rests upon the laborer that rests upon all men, so to use his free hours as to benefit himself, his family, and society."

These principles are sound, and if a true adjustment of such industrial questions is to be reached, it must primarily be on the basis of physiological requirements.

WAR AND PSYCHANALYSIS.

Many interesting revelations in the domain of functional nervous disorders have been disclosed by the present European war. In the first place, the old dictum that nervous conditions do not manifest themselves externally has been verified by the large number of neurotic candidates that passed the physical examination only to break down under the first severe strain in the training camps or trenches. It is quite evident that only men with strong constitutions are fit for the mental and moral shocks of war. Another important observation derived from a survey of the nervous victims is the realization that modern warfare imposes tremendous nervous tension and mental strain, so that adequate provision should be made to take care of all the neuropaths. This is a phase of preparedness that we should do well to keep in mind, and in which we may profit by the experience of others. Finally, some interesting light has been gained from the war concerning Freud's theories of the psychoneuroses, and the value of psychanalysis as a form of mental training. The severe demands of war and the rigid discipline of military training have quickened the instinctive emotions and transformed the repressed energies into great and heroic bravery. Suppressed desires and buried complexes may be factors in the blight of overcivilization, but in time of war these primal instincts find an outlet for themselves in the call of duty and patriotism. However helpful psychanalysis may be in time of peace, in time of war such methods appear unnecessary and undesirable. In fact, the conviction is forced on us that well directed discipline is superior to psychanalysis at all times, and that personal development and happiness cannot be divorced from self sacrifice. It is fair to assume that some of the concepts regarding the fixation of the libido, and the correct psychanalytical treatment will be greatly influenced by the experiences of the war.

COUGH AND THE LINGUAL TONSIL.

In his address as president of the Section in Laryngology of the Royal Society of Medicine, delivered on November 3rd, Mr. T. Mark Hovell, according to the *British Medical Journal* for November 18th, dwelt on the part played by enlargement of the lingual tonsil in the production of paroxysmal cough. He said that the tickling cough which was common after influenza, and might follow a simple cold or occur without known cause, was frequently due to enlargement of the lingual tonsil, the cough apparently being produced by the swollen tissue coming into contact with the epiglottis. A solution of chloride of zinc, fifteen to thirty grains to the ounce, with a trace of dilute hydrochloric acid to dissolve the salt thoroughly, was in many cases sufficient to remove the trouble, but the best remedy was trichloracetic acid, applied on a wool holder bent at a right angle, with only a very thin layer of wool attached to it, so as to insure the quantity of acid being small. A mirror should be used so that the acid might be placed accurately on the swollen tissue. He related two cases, in one of which paroxysmal cough had been very troublesome for fifteen and in the other for seven years; in both the cough diminished as the swelling of the lingual tonsil decreased.

News Items

Changes of Address.—Dr. William Van Pelt Garretson, to 11 East Forty-eighth Street, New York.

Endowment Fund of the Woman's Medical College of Philadelphia.—Announcement is made that on Wednesday, December 13th, $80,000 had been subscribed of the $200,000 which the college is endeavoring to add to the endowment fund of the institution.

Harvey Society Lectures.—The next lecture in the course will be given on Saturday evening, January 13th, by Professor E. V. McCollum, of the University of Wisconsin, his subject being the Supplementary Dietary Relationships Among Our Natural Foodstuffs.

Philadelphia Clinical Association.—The following officers have been elected to serve for the year 1917: President, Dr. Edward S. Saylor; first vice-president, Dr. Carl Lee Felt; second vice-president, Dr. C. S. Barnes; treasurer, Dr. William McKeoge; secretary, Dr. William Ruoff; governors, Dr. B. F. Devitt, Dr. C. S. Falls, and Dr. Edward Moore.

Meetings of Medical Societies to Be Held in Philadelphia during the Coming Week.—Tuesday, December 26th, West Philadelphia Medical Association; Wednesday, December 27th, County Medical Society; Thursday, December 28th, Pathological Society, Northwest Branch of the County Medical Society, Stomach Hospital Gastroenterological Society; Friday, December 29th, Medical Club (directors).

Civil Service Examinations.—Among the positions for which the Civil Service Commission of the State of New York will hold examinations on January 27th is that of intern in the Oneida County Hospital, Rome, N. Y., salary $900 a year, with maintenance. Candidates must be licensed medical practitioners or be eligible to take the licensing examination in New York State. An unmarried man is preferred. For full particulars address the State Civil Service Commission, Albany, N. Y.

Public Health Lectures in Boston.—A course of free public health talks is being given under the auspices of the Massachusetts Homeopathic Hospital, at the Department of Clinical Research and Preventive Medicine, Evans Memorial, on Tuesday evenings, at 8 o'clock. The course began on November 7th, with a lecture on Infantile Paralysis, by Dr. Mark W. Richardson, and will continue through December, January, February, March, and April, the last lecture being on April 24th by Dr. Orville R. Chadwell, on the Summer Care of Babies.

A Memorial to Doctor McCorkle.—It is announced that the late Dr. John A. McCorkle had set aside, in trust, bonds of the market value of $50,000 which became payable to the Long Island College Hospital upon his death; and for that reason this gift was not known at the time of the reading of his will. It is one of the largest gifts that has ever been made to a medical college and hospital by a physician in active practice. A committee of prominent citizens, headed by the Hon. Edgar M. Cullen, is endeavoring to raise an equal amount as a memorial fund to the late Dr. John A. McCorkle.

Medical Society of the County of New York.—A stated meeting of this society will be held in Hosack Hall, New York Academy of Medicine, Tuesday evening, December 26th, under the presidency of Dr. Frederic E. Sondern. An important feature of the program will be a memorial presenting the medical aspects of birth control, by a special committee composed of Dr. A. Jacobi, Dr. A. L. Goldwater, Dr. M. C. O'Brien, Dr. S. A. Tannenbaum, Dr. Frank Van Fleet, Dr. Charles E. Nammack, Dr. H. C. Taylor, Dr. W. H. Bishop, and Dr. G. W. Kosmak. The subject of infantile paralysis will be discussed as follows: Its clinical aspects, by Dr. Philip Van Ingen; its communicability, by Dr. Charles Gilmore Kerley; and the work of the health department in controlling it, by Dr. Haven Emerson, commissioner of health. The January meeting of the society will be devoted to a discussion of Compulsory Health Insurance.

Harvard Medical School.—At the last meeting of the president and fellows of Harvard University, six appointments were confirmed and the award of thirty-five scholarships in the Harvard Medical School was announced. Dr. Francis M. Rackemann was made alumni assistant in medicine, Dr. James H. Means and Dr. Joseph C. Aub were appointed teaching fellows in medicine; Dr. Harry C. Solomon, instructor in psychiatry; Dr. Charles E. Sandos, assistant in psychiatry; Dr. Charles A. McDonald, assistant in neurology.

Personal.—Dr. Joseph Sailer, professor of clinical medicine, University of Pennsylvania, delivered an address at the New York Academy of Medicine, Thursday evening, December 21st, his subject being Clinical Aspects of the Diseases of the Ductless Glands.

Dr. Arthur Allen Struthers, of Cliftondale, Mass., sailed from San Francisco, Cal., on December 19th for Melbourne, Australia, where he will take charge of a homeopathic hospital.

Dr. Henry A. Bernstein has been elected obstetrician and associate gynecologist to the Beth David Hospital, Lexington Avenue and 113th Street, New York.

Convocation Week Meetings of Scientific Societies.—The American Association for the Advancement of Science and many national scientific societies will meet in New York during convocation week, beginning Tuesday, December 26th. Among the national societies to meet at that time are the following: American Chemical Society, Eugenics Research Association, American Psychological Association, American Association of Bacteriologists, American Association of Anatomists, American Physiological Society, American Society of Biological Chemists, American Society for Pharmacology and Experimental Therapeutics, and the American Society for Experimental Pathology. The last named four societies compose the Federation of American Societies for Experimental Biology, whose executive secretary is Dr. Peyton Rous.

St. Nicholas Hospital.—This is the name of a new hospital which is to be erected in the near future in the Washington Heights section of New York. It will occupy a site running through the block between St. Nicholas and Edgecombe Avenues at 148th Street. The first building will be erected as a unit, and, according to plans now being prepared, this unit will be a five story fireproof building, with accommodations for sixty patients. Twenty of the beds will be in wards, wholly or in part free, and forty beds will be in private rooms. The plan and general scope of the institution will be submitted to the Hospital Committee of the American College of Surgeons for approval. This will be the first institution in New York to come under the initial supervision of this committee. The site has been donated and a large part of the necessary building fund has been subscribed. Dr. Harlow Brooks has been appointed supervisor of the medical division, Dr. Seth M. Milliken will have charge of the surgical division, and with him will be associated Dr. John T. Moorhead.

Diet Kitchens in Base Hospitals.—Members of the Seventh New York Regiment who have just returned from the Mexican border brought news of one feature that may prove of interest to medical men. In August, during the time of the 100 mile hike, many men were returned to the camp suffering from gastroenteritis and intestinal indigestion as a result of heat exhaustion and being unable to eat the regular rations. Dr. C. Perley Gray, the medical officer in charge of the camp, felt that something should be done to restore these men to health and enable them to return to duty in the shortest possible time. This need was met by establishing, for the first time in the Federal Army, as far as the men of the Seventh know, a diet kitchen. The Lieutenant Colonel heartily endorsed the idea when it was brought to him and it was carried into effect. The results were most gratifying. Most of the men were restored to health in a remarkably short time and they returned to light duty within twenty-four to thirty-six hours. The idea was adopted at the base hospital later.

A Division of Occupational Diseases at Union Hospital.—At the last meeting of the medical board of Union Hospital, Borough of the Bronx, a department for the treatment of occupational diseases was established, with Dr. Frederick W. Loughran, a member of the staff, as attending physician in charge.

An examination of the history cards at almost any hospital will show that but little attention has been paid to the occupation of the patient, and while deaths from occupational diseases are very rare, it is because a secondary disease terminates the condition brought about by the occupation. Many hospital patients are, no doubt, suffering from diseases partly occupational, and it is to this class of patients that the greatest care will be given in compiling their histories, for with an accurate history, the diagnosis of the specific occupational disease is comparatively easy, and with an intensive inquiry into personal, environmental, and industrial hygiene, it is hoped that the effort to correlate these occupational health hazards with the other etiological factors in the case will be productive of good results. Patients, before their discharge, will be instructed in methods of preventing or lessening the dangers that surround them while at work; and should the opportunity offer, employers will be advised as to the value of industrial hygiene.

American Association for Labor Legislation.—The tenth annual convention of this association will be held in Cincinnati, Ohio, December 27th to 30th. A preliminary program has been issued by the secretary, Dr. John B. Andrews, which provides for seven sessions to be held for the discussion of health insurance and the eight hour day.

Addresses on these subjects will be given by leading scientific authorities and representatives of labor. The Need for Health Insurance is the subject of a paper to be given by the president, Professor Irving Fisher, of Yale University; Miss Julia Lathrop, chief of the Federal Children's Bureau, will discuss the Public Protection of Maternity; Miles M. Dawson, insurance actuary of New York, will discuss The Principles of Health Insurance, while Dr. Alexander Lambert, chairman of the Social Insurance Committee of the American Medical Association, will discuss Medical Organization under Health Insurance, and the Hon. John J. Lentz, president of the American Insurance Union, will discuss the Fraternal Societies under Health Insurance.

Simultaneously with this meeting conventions will be held in Columbus of the American Economic Association, the American Statistical Association, and the American Sociological Society.

War Hospital Motion Pictures.—An exhibition of film views of hospital work on the western war front was held on Saturday evening, December 16th, in Houston Hall, Philadelphia. The program was as follows: Film I. Dr. Alexis Carrel, of the Rockefeller Institute, demonstrated his latest methods at the Hospital Rond Royal at Compiegne. Film II. Plastic surgery of the face and jaw, by Doctor Pont, at Lyon. Film III. Reeducation centre at Vizille, showing corrective exercises devised especially for the cure of functional nervous conditions contracted in the trenches. Film IV. Extraction of a shrapnell ball from the region of the heart, by Professor O. Laurent at the Grand Palais. Film V. Functional conditions contracted from life in the trenches, a common result of the exposure and nerve strain of trench life. Film VI. American method of bone grafting, as performed in European war hospitals, by Dr. Fred. H. Albee, of New York. Dr. Edward Martin, John Rhea Barton professor of surgery, discussed the educational value of the surgical films. Dr. Dudley Guilford, of the staff of the American Hospital Ambulance at Neuilly, France, spoke on the subject of prosthetic restoration of the face and jaw mutilated by gunshot wounds. Major R. Tait McKenzie, R. A. M. C., director of the department of physical education at the University of Pennsylvania, recently returned from active service where he was in medical command of a convalescent camp of 6,000 men, explained methods of physical therapy and results obtained in the salvage of men in these camps.

American Congress on Internal Medicine.—This organization, which is chartered under the laws of the State of New York, will hold its first scientific session on December 28th and 29th in New York, with headquarters at the Hotel Astor. Dr. Reynold Webb Wilcox, president of the congress, will call the meeting to order on Thursday morning, at 10:30 o'clock, with an address on the Domain of Internal Medicine and the Purport of the Congress. The subject selected by the council of the congress for discussion at the afternoon session is The Ductless Glands in Cardiovascular Diseases and Dementia Præcox. Dr. Charles E. de M. Sajous, of Philadelphia, will act as referee, with Dr. Judson Daland, of Philadelphia, as coreferee for cardiovascular diseases, and Dr. Francis X. Dercum, of Philadelphia, as coreferee for dementia præcox. The discussion will be opened by Dr. Harlow Brooks and Dr. Smith Ely Jelliffe, of New York, and Dr. William A. White, of Washington, D. C. On Friday morning, at 10:30 o'clock, a meeting of the council of the American College of Physicians will be held, and the program for the afternoon session consists of a symposium on Duodenal Ulcer. Papers will be read as follows: The Diagnosis of Duodenal Ulcer, by Dr. John B. Deaver, of Philadelphia; The Prognosis of Duodenal Ulcer, by Dr. Max Einhorn, of New York; The Possible Dependence of Gastroduodenal Ulcer in Man Upon a Disturbance of Internal Secretion, by Dr. G. A. Friedman, of New York; Venous Stasis and Colloidal Diffusion as Etiological Factors of Gastroduodenal Ulcer, by Dr. Fenton B. Turck, of New York. On Friday evening, at 8:30 o'clock, the convocation of the American College of Physicians will be held. For further information regarding the congress, address Dr. Heinrich Stern, secretary-general, 250 West Seventy-third Street, New York.

Symposium on Cancer.—In connection with the forthcoming convocation of the American Association for the Advancement of Science in New York, physicians, public health workers, and others interested will be given an opportunity to hear addresses of unusual scientific distinction on various phases of the cancer problem. Section K of the association, which is devoted to Physiology and Experimental Medicine, has given over its entire program to a cancer symposium to be presented at a meeting at the American Museum of Natural History, Columbus Avenue and Seventy-seventh Street, at 2:30 p. m. on Friday, December 29, 1916. The American Society for the Control of Cancer has been invited to cooperate in bringing this important meeting and its results to the attention of the medical profession and the public. A comprehensive program covering the biological, clinical, therapeutic, and educational phases of the cancer problem has been arranged by Professor E. O. Jordan and Professor C. E. A. Winslow, respectively chairman and secretary of Section K. Professor Gary N. Calkins, of Columbia University, will discuss The Stimulating Effects of Protoplasmic Substances on Cell Division. Professor Leo Loeb, of the Medical School of Washington University, St. Louis, will read a paper on Tissue Growth and Tumor Growth. Dr. Joseph C. Bloodgood, of Johns Hopkins University, Baltimore, will speak from the surgeon's point of view on Cancer in the Human Being, with special reference to preexisting lesions which favor the development of cancer. Dr. James Ewing, of Cornell University Medical College, will summarize the latest experience and conclusions regarding the use of radium in the treatment of cancer. Doctor Ewing is director of Cancer Research at the General Memorial Hospital, which through the generosity of Dr. James Douglas is now receiving, together with the Johns Hopkins University Hospital, the greater part of the radium produced by the United States Bureau of Mines in cooperation with the National Radium Institute. Mr. Curtis E. Lakeman, executive secretary of the American Society for the Control of Cancer, will give an account of past and present efforts to combat this disease through the education of the public. Although of special interest to practitioners of medicine and to those concerned with the scientific aspects of the cancer question, the meeting will be open to the public.

Modern Treatment and Preventive Medicine

A Compendium of Therapeutics and Prophylaxis, Original and Adapted

THE THERAPEUTICS OF A PHARMACOLOGIST.

By A. D. Bush, M. D.,
Professor of Pharmacology and Therapeutics, University of Southern California.

Forty-ninth Communication.

NEURASTHENIA.

It is fully as important in medicine to know what not to do as it is to know how and when to use specific measures; in fact, omission can be as specifically indicated in therapeutics as commission; hence the justification for including a consideration of neurasthenia in a discussion of pharmacological therapeutics.

More or less temporary departures from the mental normal, whether shown in neurasthenia or in the more aggravated types manifesting hysterical symptoms, have their immediate origin in an undue irritability of the nerve centres or areas, whether the deeper source is congenital or acquired. These nerve areas may receive sensory impulses from any peripheral area, or they may be the centres of association paths in the intracranial areas. In either case there would seem to be present an impressional activity in excess of the capacity of such structures involved, followed by a depression below par of the functional power of that area, and a presumptive outflow of imperfectly metabolized products, physical or psychical.

Almost any of these cases may prove a challenge to the physician's diagnostic acumen; but the diagnosis must be correctly made or treatment may readily prove injurious. Dr. S. Weir Mitchell shrewdly divined the tremendous advantage to be gained by complete mental and bodily rest as a first step, either of treatment or of diagnosis. The effect of such a preliminary measure is of great importance in any neurasthenic condition.

The next step is to purge the system of accumulated toxins. So far as the alimentary and circulatory systems are concerned, this is accomplished by means of gentle cathartics and a restricted definite diet, but it is not so easy a matter to deal with the mental side. And here a strong word of caution is needed, especially since our aim is to promote rest. Perhaps not infrequently, by means of the hypnoidal state, some mental thorn is discovered, removal of which by mental suggestion serves a highly beneficial therapeutic end; but we must be absolutely sure the mental thorn has a definite reality with the subject and is not merely a fantastic postulate of the operator. Such unwarranted postulates are being disclosed in various pseudoscientific disquisitions of psychanalysis concerning the interpretation of dreams, the method of which seems to consist largely in clothing the soothsayer's ideas with the jargon of science. Apparently the analyst concocts an array of *a priori* predicates into which he aligns such of his subject's dream state reactions as seem most plausibly to complete the phrase, especially if by any conceivable twist of a disordered fancy the operator can imagine a possible pudendal connotation. And this he calls scientific, when as a matter of fact such gypsy dogmatisms are at the very antipodes of rational medicine

Having accurately determined the real nature of the irritant, and having removed it by the most wholesome means available, it becomes necessary to develop constructive activities, both mental and physical; and this requires a careful, comprehensive education of how to employ the faculties most efficiently and hygienically. Deficiencies from earlier training must now be compensated; errors in living and thinking must be rectified; the whole tone of life needs regeneration, the body needs regular exercise and occupation, the mind needs to be freed of morbid introspection and set to broad inspiring tasks. No formal set of rules can be outlined, since each patient is a law unto himself; so the physician will need to exercise his shrewdest ingenuity and his most exalted altruism to discover the hidden springs of action and to get his patient safely started on the highway to recovery.

Excluding such agents as hemic dyscrasias might demand, about the only drug with indications in these cases is strychnine, used here for its indirect acceleration of metabolism. Cerebral depressants of every nature should be tabooed.

Comparative Value of the Methods of Treating Tetanus.—Charles Langdon Gibson (*American Journal of the Medical Sciences,* December, 1916) discusses the treatment of tetanus in the present European war as exemplified in England, Italy, France, and Belgium; and gives special attention to the comparative assertions concerning treatment with antitoxin, magnesium sulphate, and carbolic acid. With regard to the antitoxin treatment, the subcutaneous method of administration is believed to lack efficiency, so it should be used only as an adjuvant to the other methods. The intravenous administration is more efficient and rapid, but still should be considered an accessory rather than the main line of treatment. The intraspinal method seems to comply with the indications, and to locate the antitoxin most directly in the lesion itself. Large doses are indicated in this manner. When intraspinal injections are employed there is little call for intraneural injections, which demand an operation under anesthesia. Intracerebral injections have been abandoned, as they gave poor results. Treatment with magnesium sulphate was originated in the United States by Meltzer and Auer, and Meltzer's summary of the method is given. It can be administered intraspinally, subcutaneously, intravenously, or intramuscularly, but the general impression in New York city is that it has too many dangers and drawbacks, particularly in paralyzing the respiration. Yet in the present war it seems to stand out as prominently as any one method in Germany, and is

used to some extent in other countries. The mortality alleged for the carbolic acid treatment, in which a one per cent. solution is injected every few hours, preferably into the muscles along the spine, is the lowest of all, seventeen per cent. It has not come into general use in America. Throughout this paper it is presumed that the wound treatment has been that suitable to the injury, to prevent the harboring or development of tetanus germs. He doubts if we are justified today in performing an amputation to relieve tetanic manifestations. He omits all questions of nursing and of sedatives, except that he alludes to chloretone as having had curative qualities attributed to it. He is also inclined to try atropine to control spasms. Antitoxin treatment should begin immediately on suspicion of tetanus rather than wait on the classical symptoms. It should be given at once, say 1,500 units, into the wound or the region of the wound, and intraspinally, 5,000 to 20,000 units, without an anesthetic, unless this is called for by the treatment of the wound. In the course of the first twenty-four hours 10,000 to 20,000 units additional should be given intravenously in two or three divided doses. The next day from 5,000 to 15,000 units should be given intravenously, no matter whether the symptoms remit or increase. On the third day, if the patient's symptoms continue to be severe, or appear worse, in spite of the treatment, the intraspinal injection should be repeated. This causes a temporary increase of symptoms and a great elevation of temperature, but this fact need not cause alarm. After this the intraspinal injection need not be repeated if the patient holds his own or improves, but the intravenous injection of antitoxin should be made daily until obvious remission or cure results.

Tetanus.—Hugo Pribram (*Medizinische Klinik*, October 22, 1916) summarizes his views of the modern advances which have been made in the treatment of this serious disease. He expresses considerable skepticism as to the therapeutic value of tetanus antitoxin and has employed it but sparingly. The same is true of the use of the serum of persons who have recovered from an attack. The most important elements in the treatment are the general management, and the control of the convulsions. The former demands the most complete quietude possible, with elimination of all forms of external stimuli, including light and even slight noises. Feeding should be carried out in the least disturbing manner and where it is impossible to get the patient to swallow his food rectal administration should replace the use of the nasal tube. Amputation of the infected extremity is not advised, but the wound itself should be treated along general surgical lines so modified that free exposure of it is given to the open air. Oxidizing agents should be used in the dressings, among which the most serviceable are pure oxygen, hydrogen peroxide, bolus alba, and calcium chlorate. Absorptives such as blood charcoal are also very useful. For the control of convulsions ether, chloroform, morphine, and the many fixed narcotics should be used freely. Ether and chloroform are to be employed only for the temporary relief of very severe attacks, and reliance should be placed chiefly upon large and frequently repeated doses of morphine, combined with alternating doses of hydrated chloral, urethane, or luminal to maintain an adequate degree of narcosis. Magnesium sulphate may be used intraspinally, intravenously, intramuscularly, or by subcutaneous injection, but the first of these methods of administration is the least desirable because the most dangerous. The most suitable for general use is the administration of three or four subcutaneous doses daily of from five to twenty mils each of a twenty-five per cent. solution. For the control of the dangerous effects of magnesium, physostigmine, calcium chloride, and artificial respiration must be employed. The last two are the most certainly effective, and the calcium chloride must be ready for immediate subcutaneous injection in the form of a five per cent. solution, of which five mils may be injected if needed. Phenol, curare, etc., have been recommended, but the evidence in favor of their use is not convincing. Recently the subcutaneous injection of deuteroalbumose has been warmly advocated, but the author has had no experience with its effects. The most satisfactory use of the hypnotics demands their employment alternately, thus insuring the maximum effects with the minimum dangers. Their use should be continued in diminishing doses for some time after the severe symptoms have disappeared to prevent the possible recurrence of violent convulsions.

Gunshot Wounds of Peripheral Nerves.—Byron Stookey (*Surgery, Gynecology and Obstetrics*, December, 1916) concludes as follows with regard to such wounds: 1. With the use of high explosives and bullets with high velocity the frequency of nerve lesions has increased. 2. Peripheral nerves may be injured by direct violence of projectile and by the violence imparted to bits of bone or even foreign bodies. 3. Peripheral nerves may be implicated secondarily by scar tissue, or callus, or both. 4. Diagnosis cannot be made before operation between anatomical and physiological division. Diagnosis can usually be made in cases with incomplete division. 5. In war surgery primary suture is rarely possible due to infection. 6. Exploratory operation is indicated when a diagnosis of complete division is made. Delay in operating usually means delay in return of function. 7. Nerve freeing is in many cases to be preferred to excision and suture. When the nerve is widely implicated and there is a large loss of continuity, it is better to do nerve transference or nerve transplantation than tubulization or suture with the nerve under tension. 8. Stretching of the nerve should not be done, as it causes caryolysis of the nerve cells in the anterior horn with subsequent degeneration of the nerve axon in the proximal nerve trunk. 9. Efficient splinting to prevent contractures and overstretching of the muscles is imperative, both before and after operation. 10. The terms epicritic and protopathic tend to be confusing. Greater accuracy is obtained in the use of specific terms as area of cotton wool, area of pinprick, areas of moderate and extreme degrees. 11. Musculospiral nerve injury in its lower third shows loss of sensation on a narrow band or over the dorsum of the thumb, usually only a loss to cotton wool and temperature sense. 12. Injury to musculospiral nerve may cause dissociation of temperature sense

in the area on the dorsum of the hand—without loss to cotton wool. 13. The median nerve does not supply any skin on the dorsum of the thumb; it supplies up to a line in continuation of lateral borders of nail. 14. The anterior cutaneous division of the ulnar nerve supplies the skin in the same manner as does the median nerve, i. e., on to dorsum of fifth and part of fourth, middle, and distal phalanges. The posterior cutaneous division supplies the ulnar side of the hand and the proximal phalanx of the fifth and part of the fourth. 15. The action of extensors assists the interossei in separating the fingers. To test for paralysis of the interossei have the patient bend his fingers at right angles at metacarpal phalangeal joints; prevent effort of extensors by holding the fingers across; then have the patient try to separate his fingers gently. 16. Return of motor function begins with the muscles which first receive their supply below the lesion. The return is earlier the nearer the lesion is to the periphery. 17. Trophic ulcers occur only after trauma. Their repair appears to be no different from that in other parts. 18. Functional disorders may be superimposed on organic peripheral nerve lesions. Usually they are readily recognized.

Observations on Tetanus.—L. Sexton (*New Orleans Medical and Surgical Journal*, December, 1916) says that we should endeavor to keep the bowels well open and the kidneys active, in order to eliminate as much of the poison as possible. The irritability of the spinal cord should be controlled by large alternating doses of sedative medicines, including chloroform, to control the spasms. Toxins are prevented from entering the system by thorough disinfection of the wound. He injects two thousand units of antitetanic serum in the vicinity of the wound, or between the wound and the spinal cord. If the wound is upon the hand he makes the injection near the brachial plexus; if on the foot, near the sciatic nerve. Intraspinal injection of fifteen hundred units of antitetanic serum is the best and quickest way to apply the remedy to the spinal cord. The same amount of spinal fluid should be allowed to escape before the injection of the serum. Rectal or nasal feeding may become necessary when it is impossible to get food into the mouth on account of a spasm of the jaws. Sometimes a tooth must be extracted to facilitate the introduction of nourishment.

Alkaline Hypochlorites in Disinfection of the Hands.—Loebelongue and Dubard (*Bulletin de l'Académie de médecine*, October 31, 1916) report bacteriologic tests in which the disinfecting activities of the alkaline hypochlorites were compared with those of tincture of iodine. Surface disinfection with the latter proved uniformly effectual in five tests, but disinfection at a depth proved imperfect, nail clippings giving positive cultures in four out of five cases. Of the hypochlorites, magnesium hypochlorite and a mixture of the hypochlorites of calcium and magnesium were used. Surface disinfection with a solution yielding 1.8 to two per cent. of chlorine was effectual after six minutes' immersion in four out of five trials, and with a solution yielding 2.5 to three per cent. of chlorine, uniformly effectual. Deep disinfection was likewise uniformly perfect with the latter solution, though with the 1.8 to two per cent. preparations, two out of five tests yielded colonies of Bacillus subtilis. In thread tests, sterilization of colon bacilli and staphylococci was obtained by four minute immersion in a 1.8 to two per cent. preparation, and in two minutes in a 2.5 to three per cent. preparation. Bacillus subtilis was sterilized by four to five minutes' immersion in the stronger preparation. Exposure of cotton swabs impregnated with cultures of Bacillus subtilis to vapors of iodine and alcohol liberated from boiling tincture of iodine failed to sterilize any of the swabs in eight minutes. Similar swabs exposed to the chlorine liberated by a solution of chloride of lime were sterilized in three to four minutes. The solution of alkaline hypochlorites containing no protein coagulent, its penetration through the skin is not impeded. In practice, surgical cleanliness of the hands is therefore obtainable by immersion in a 1.8 to two per cent. preparation for eight minutes, or in a stronger preparation for four to six minutes. The results are superior to those obtained under like conditions with iodine.

Treatment of Angina Due to Fusiform and Spirillar Organisms.—M. Favre and H. Dreyfouss (*Presse médicale*, November 2, 1916) point out that while the lesions due to the fusospirillar symbiosis are at times primary, as in Vincent's angina and in certain cases of ulceromembranous stomatitis, they are more often secondary to conditions lowering local resistance such as dental caries, the inflammation resulting from eruption of a wisdom tooth or mercurial elimination, and various buccopharyngeal ulcerations, including the syphilitic chancre. The diagnosis, important because of the rebelliousness of the condition to ordinary antiseptics, is readily made, not only with the microscope, but from the irregular nature of the ulcerations, with bright red margins, putrid layer at the base, removal of which easily excites bleeding, the foul breath, rather intense pain, and functional signs such as trismus or dysphagia. Though the treatment with organic arsenicals such as neosalvarsan and galyl is recognized as specific, the authors find a combined silver nitrate and methylene blue treatment equally efficacious, simpler, and less expensive. The ulcerations are very carefully cleansed every day with small swabs of cotton previously dipped in a ten per cent. solution of silver nitrate in distilled water. The bases of the ulcers must be made quite clean, regardless of the amount of bleeding induced. A one per cent. methylene blue solution is then freely applied. In cases of Vincent's angina the tonsils are carefully examined and the recesses in the crypts, in which the infection often starts, duly explored. By the second or third treatment, improvement is already manifest. The ulcer soon shows healthy, firm granulations. A one in thirty silver solution is thereafter sufficient, the treatment being kept up until complete recovery has occurred. By this method disappearance of the more superficial lesions, as ordinarily met with on the internal surface of the cheeks, was procured in three days, and of extensive tonsillar ulcerations, destroying nearly all the tonsillar tissue, in eight days. Where the treatment fails, the authors do not hesitate to affirm that some other morbid factor coexists.

Pubiotomy in Impacted Face Presentations.—Paul Titus (*Surgery, Gynecology and Obstetrics*, December, 1916) believes that the following conclusions are justifiable in cases of mentoposterior face presentation seen after engagement: 1. That a reasonable test of second stage should be allowed the patient in the hope that anterior rotation will take place, either spontaneously or with the assistance of carefully performed manual attempts at rotation. 2. That attempts to rotate by means of forceps are dangerous to both the child and the mother. 3. That Cæsarean section is directly contraindicated because of its high mortality in these cases. 4. That craniotomy is the operation of choice if the child is dead or dying, but that it is by no means as innocuous as is generally assumed. 5. That pubiotomy is the operation to be selected in those cases where the child is alive and in good or even fair condition, and that craniotomy on a living child presenting in this fashion is entirely unjustifiable.

Treatment of Amebiasis by Adrenaline.—Theodoro Bayma (*Annaes Paulistas de Medicina y Cirugia*, August, 1916) after eighteen months of investigation is convenced that adrenaline is of remarkable value in amebic infection whether it is evidenced by dysentery, hepatic localization, or appendicular involvement. Of sixty cases thus treated twenty-eight were acute and thirty-two chronic, and all were cured in from two to thirty days. The treatment was quite without untoward effect even in early infancy and advanced old age. The adult dose was twenty to thirty drops four times daily, and in liver abscess the one to 1,000 solution was injected into the abscess cavity after evacuation of its contents. Tropical appendicitis is the term applied by Fausto to the localization of the entameba in the appendix. This condition yielded to the administration of adrenaline by mouth and the application of icebags to the abdomen. Recurrences are much more rare than under the emetine treatment.

Reduction of the Size of the Heart by Corpuscular Radiotherapy.—E. Zueblin (*Lancet-Clinic*, November 11, 1916) presents a preliminary report of clinical results obtained in cases of acute and chronic cardiac dilatation, and dilatation of the arch of the aorta by brief application of intense radioactive energy over the heart. The patient is placed within the field of radiation of two specially constructed electrodes which receive their energy from the secondary current of a powerful Rhumkorf apparatus. One to five minutes of this treatment, with a current of from five to ten milliampères in the primary coil, breaks up the atoms of the tissues into their component corpuscles or electrons, thereby rendering the tissues radioactive and altering their physical and chemical properties. In advanced cases of cardiac dilatation, even where ordinary therapeutic measures have proved unsuccessful, the treatment causes an immediate, marked reduction in the size of the heart, which continues to contract well for some days and remains small thereafter for a prolonged period. Subjectively and objectively, a rapid improvement in the patient's condition is noticed. The treatment has also been successfully used in local edema, and in arthritis, neuritis, and pleurisy.

Treatment of Epilepsy.—William Held (*Maryland Medical Journal*, December, 1916) avers that epilepsy is a toxemia in which the first essential condition is the proneness of the blood to absorb and store up toxins derived from waste products. Epilepsy cannot be acquired by a person whose blood lacks this affinity for toxins. Thus the serum treatment of the disease holds out the brightest hope at this time.

Vaccines in Respiratory Diseases.—B. F. Stout (*Texas State Journal of Medicine*, December, 1916) as a result of his experience states that vaccines are of value in all forms of respiratory infection, especially in the subacute and protracted infections. They are less successful in the very acute and very chronic cases. Success depends upon the use of strains which are capable of producing an immunizing response. Where an autogenous vaccine fails trials should be made with a vaccine of proved value in a similar infection.

Treatment of Chronic Ulcers.—E. Alvarez Sainz de Aja (*Revista de Medicina y Cirugia Practicas*, November 14, 1916) recommends the application of a lead plate to chronic ulcers, especially of a varicose nature, as first advised by Ledo in 1909. A thin plate of lead is cut to approximately the shape of the ulcer and is firmly bandaged thereto. This plate is removed daily and the ulcer washed with permanganate solution, and then the plate is reapplied after washing in hot water. In the final stage of healing, the plate may be put aside and dressings of one half per cent. picric acid, one in thirty scarlet red ointment, or one per cent. ichthyol used.

Surgery in Intestinal Toxemia.—Jerome M. Lynch and John W. Draper (*Medical Record*, December 2, 1916) take up the advantages and disadvantages of the various operations for this condition. Ileosigmoidostomy benefits a number of cases, but because of anastalsis ten per cent. of such cases require a subsequent colectomy. Cecosigmoidostomy is deficient both theoretically and practically, as its employment leaves out of consideration the law that intestinal contents tend to follow the normal direction of the canal irrespective of lateral stomata. Appendicostomy is safe, but insufficient in most cases; while ileostomy is of benefit in severe colonic infections but of limited indications. Plication of the cecocolon is unreliable as to permanency of results. A new operation just described by Strauss of total colonic exclusion has not yet proved its worth. Colectomy is indicated in diffuse polyposis, papillomatosis, diverticulitis, and in certain malignant tumors, but the mortality is high and elimination is interfered with by the removal of omentum and the terminal colon. The best operation in selected cases is what the writers call developmental reconstruction, which is the resection of the terminal ileum, the cecocolon, and the oral part of the transverse colon. This operation reconstructs the colon to the primitive or developmental type as seen in the adult dog, and in the human fetus just following rotation. The use of colonic vaccines is safe, it is usually of service, and it places the patient in the best possible condition for any necessary later operation.

Salvarsan in the Treatment of Double Infections, Tuberculosis and Syphilis.—Nathaniel Bowditch Potter (*American Journal of the Medical Sciences*, December, 1916) gives his opinion that the prompt employment of salvarsan or neosalvarsan is indicated in latent, chronic, and moderately active tuberculosis as soon as the nature of an added infection is diagnosed with reasonable probability to be syphilis, or whenever a previous luetic infection is strongly suggested, and the patient is not improving under usually successful treatment. But active, acute, and diffuse miliary tuberculosis usually are definite contraindications to their use. The careful use of one of these drugs is indicated when tuberculosis infects a syphilitic. The more active the tuberculosis the smaller should be the initial dose, the slower the increase, the longer the interval, and the greater the care and watchfulness required.

Recent Experience with Ipecac and Its Alkaloids.—Sidney K. Simon (*New Orleans Medical and Surgical Journal*, December, 1916) reports his investigation of the influence upon amebiasis of cephaline, an alkaloid closely resembling emetine, and like it derived from the ipecac root. Cephaline seems to possess an amebicidal action upon the free living entamœbæ to a degree equal to that of emetine in the same dose. Its destructive effect upon the encysted organism appears to afford more promise of success than that induced by emetine. Its subcutaneous use causes considerably more irritation and pain. Gastric disturbances with nausea and vomiting are more frequent and greater with cephaline than with emetine, but there is less tendency to diarrhea in the course of treatment. The employment of a combination of the two alkaloids by hypodermic injection would seem to promise a greater amebicidal effect than is obtained with emetine alone. No evidence of toxemia was observed following the employment of comparatively small doses of cephaline.

Treatment of Pellagra.—J. D. Perdue (*American Medicine*, November, 1916) employs the following as remedies in pellagra: Thirty drops of dilute nitric acid four times a day in a glass of water; copper arsenite, beginning with 1/100 grain and increasing it to a very large dose. As a routine method of treatment he allows meals six times a day if the stomach can tolerate them; the food is given in a semisolid form. The following foods are given: Field peas and soup of the same, lima beans, soft boiled eggs, beef juice and broth, fruits of all kinds, crackers, and loafed bread. The patient receives the following medicines in one teaspoonful doses six times a day if full doses are given, and three times a day if half doses are given: Elixir lactated pepsin, tincture of nux vomica, and Fowler's solution. For the stomatitis an alkaline mouth wash and gargle is used. The nervous symptoms are controlled by morphine or chloral hydrate well diluted. In cases where diarrhea is present bismuth in large doses with tincture of camphorated opium are given. For vaginitis potassium permanganate douches twice daily are prescribed. For skin lesions a local dressing is used consisting of two parts of iodine in 100 parts of castor oil.

Further Report on Thromboplastin as a Hemostatic.—Alfred F. Hess (*Journal A. M. A.*, December 9, 1916) states that since the introduction of thromboplastin it has been very extensively employed in various conditions for the control of obstinate hemorrhage, and he reviews the results of its use. They show that it is of great value in any form of bleeding in which it may be brought into direct contact with the bleeding area. Such conditions are found after the removal of tonsils and adenoids, in nasal work, circumcision and other operative procedures, the extraction of teeth, and for the local hemorrhages encountered in hemophiliacs. For the latter group of cases it is almost a specific. In certain cases of local hemorrhage where its topical application does not prove effective in controlling the bleeding it may be injected into the immediate region of the hemorrhage with the best results. For this purpose the one per cent. solution should be boiled for a brief time, which does not materially diminish its hemostatic properties. Experiments are also reported to show that the one per cent. solution is quite as effective as stronger ones. Further, it has been observed that the substance, either in the form of a solution, the dry powder diluted with lactose, or as an ointment has a marked power of stimulating the granulation and healing of wounds, even of the chronic and indolent type represented by old varicose ulcers.

Treatment of Tuberculous Peritonitis.—C. R. Hyde (*American Journal of Obstetrics*, September, 1916) reports two fatal cases of this condition, in one of which appendicectomy was followed by fistula formation; while in the other the patient grew progressively worse after panhysterectomy. He laments the insufficient attention given the disease by gynecologists. As diagnostic points he lays stress on persistent progress of the condition, without periods of improvement, on painful urination, and on variability of the abdominal physical signs. In the treatment, authorities agree that hygienic measures should be instituted at once, and that laparotomy is the only choice in the way of operative measures If a suspected case improves under hygienic means, we should not operate. In operating, a small incision about seven cm. long should be used. If a focus of disease can be found and removed without too much traumatism, this should be done. Thus, with no great peritoneal disturbances, slight adhesions, few or no tubercles, we are justified in removing one or both tubes if involved. With extending peritoneal involvement, however, he believes nothing should be removed. Unless there is a band shutting off a loop of intestine, or a distinct obstruction, no intestinal adhesions are to be disturbed. Where intestines are matted together in one mass, under no circumstances must any attempt be made to separate them. All serous or bloody fluid collections should, however, be sponged out, after dropping the foot of the table so as to cause all fluid to gravitate toward the pelvis. The leaving of four grams of iodoform in the peritoneal cavity is advised, and McGlynn has reported seventeen cases cured in one year with the introduction of oxygen into the peritoneal cavity. Important as a final step is the closing of the abdomen without drainage.

Miscellany from Home and Foreign Journals

Cystography.—Herman L. Kretschmer (*Surgery, Gynecology and Obstetrics,* December, 1916) concludes thus: 1. Cystography is a valuable adjunct to our present diagnostic methods. 2. Cystography will always have a limited field of usefulness. 3. Great care must be exercised in interpreting cystographs. 4. Because of its limitations and possibilities of misinterpretation, cystography can never hope to take the place of cystoscopic examination, but should be used as an adjunct to it and not instead of it. 5. Cystography may be of aid in determining whether resection or fulguration should be employed in a certain percentage of papillary tumors. 6. For outlining the number, size, and position of diverticula, cystography is certainly the method of choice. 7. That regurgitation of fluid from the bladder into the ureter is possible in normal persons has been demonstrated in some of the cases embodied in this report. 8. It has also been possible to demonstrate a regurgitation of fluid from bladder into ureter in the presence of bladder infection though the ureteral orifice appeared normal.

Diagnosis of Active Pulmonary Tuberculosis.—E. Sergent and G. Delamare (*Bulletin de l'Académie de médecine,* October 31, 1916) report observations made in a hospital in which six hundred tuberculosis suspects were kept temporarily, to differentiate between those available for military duties and those deserving of release from such service. The diagnostic methods used comprised repeated physical examinations, radioscopy and radiography, bacteriological observations, the endermic tuberculin test, and systematic studies of the body weight, temperature, blood pressure, and pulse rate. Of the six hundred subjects eighty-nine were dismissed as nontuberculous, having merely instances of anemia, dyspepsia, emaciation, mitral lesions with hemoptysis, syphilis, pulmonary hydatic cysts, or nasal disorder. Eighty-three other cases showed tubercle bacilli in their sputa; in only thirty of these had the symptoms first appeared since the beginning of the war. The remaining 428 cases were labeled "suspects" and subjected to further observation. The essential x ray evidence of tuberculosis in such instances was taken to be a veiled appearance of the lung—at the apex in two thirds of all cases—generally with a more or less evident tracheobronchial adenopathy. The veiled condition, usually bilateral and varying greatly in density, did not permit of determining whether an existing tuberculous condition was active or in a cicatricial state. The conclusion was reached that actual lung tissue change predominates where there exist manifest dullness, exaggerated fremitus, crackling rales, hemoptysis, fixation of the apical veils, absence of change in these veils on coughing, and a striated or dotted condition. Pleural changes predominate where there are slight dullness, normal or diminished fremitus, and friction sounds, together with pupillary inequality and supraclavicular adenitis. The pleural type of apical shadow, different from the pulmonary type, permits some illumination of the apex to persist after coughing. Differentiation of active from healed lesions was accomplished, not by physical examination, but by general and functional observations on the patient, and by inquiry into his family history and the day of initial appearance of the disease. In doubtful cases, the iodide test was resorted to, one gram of potassium iodide being given on five successive days, and a rise in temperature of one half to one degree signified that the cicatrix was not an old one. This test was applied, however, only where a favorable result was anticipated, the danger of lighting up a quiescent focus or inducing hemoptysis from a still active lesion being thus minimized. Of the 428 suspects, 216 were by these methods shown to be active cases and 212 healed cases. Adding to the latter the eighty-nine subjects classed as nontuberculous, 301 out of the 600 soldiers examined were shown to be undeserving of relief from military service from the standpoint of tuberculosis—a not inconsiderable saving to the armed forces and finances of the nation.

The Present Status of Blood Extract Coagulants and Blood Transfusion.—Charles G. Levison (*Military Surgeon,* December, 1916) concludes as follows: 1. The indications for blood transfusion are now fairly well defined. 2. Intravenous injections of gelatin and gum acacia afford excellent substitutes for the blood lost in hemorrhage and should be more generally employed. 3. Transfusion in advanced carbon monoxide poisoning and advanced surgical shock is valueless. 4. Transfusion is recommended as a preoperative measure in chronic jaundice and in patients that have suffered from slow hemorrhages as in carcinoma of the uterus, stomach, and intestines. 5. Local applications of horse and rabbit serum may at times be effective in controlling bleeding if human serum is without effect. 6. In chronic and pernicious anemias blood transfusion has achieved no important results. 7. In hemorrhagic blood diseases such as purpura hemorrhagica, hemophilia, and melæna neonatorum, transfusion is at times very effective. 8. Injections of whole blood from ten to thirty c. c. are almost a specific in melæna neonatorum. 9. In the chemistry of coagulation Howell's theory is the one that offers an excellent working basis in the study of coagulation. 10. Injections of whole blood intramuscularly are more effective than horse serum in controlling bleeding. 11. Kephalin and coagulen are of great importance for their local effects as hemostatics. Kephalin acts almost specifically when applied locally to the wounds of hemophiliacs. 12. Unger's method is given first place, as far as simplicity and ease of employment are concerned, as it obviates the necessity for incising the tissues. 13. Lewisohn's method is next recommended, as it requires no special apparatus and can be readily carried out. 14. A very serviceable technic is that performed with the aid of the Kimpton-Brown tube.

A New Syndrome.—Siegfried Block (*Medical Record,* December 2, 1916) describes a new symptom complex occurring in women between puberty and menopause, mostly between twenty-five and thirty-five years of age. The symptoms are sleeplessness, a melancholic tendency, attacks of crying, nervous irritability, sexual hypersensibility, loss or gain in weight, lassitude, and pigmentation. Block considers that this condition is due to an improper functioning of the ductless glands, especially those of the adrenal system. Treatment is best pursued by the use of extracts of ductless glands which in proper combination are specific. Ovarian, adrenal, and thyroid extracts combined make a good combination, and sometimes the addition of pituitary extract helps.

Streptococcus Infection as a Cause of Spontaneous Abortion.—Arthur H. Curtis (*Journal A. M. A.*, December 9, 1916) reports two cases of spontaneous abortion. From the urine of one of the women, and the heart blood and placenta of the fetus in the other streptococci were isolated. These organisms were grown and injected into pregnant rabbits, with the result that they either produced abortion or led to death and beginning absorption of the fetus in every instance. One of the women seemed to be in normal health at the time of her abortion, the other was suffering from a pyuria due to the organism in question. These observations indicated that the particular streptococcus isolated in these cases had a special selective affinity for the genitourinary passages and was capable of causing abortion. This adds one more definite infectious agent to those known to cause death of the fetus.

Cerebrospinal Meningitis. — W. J. Denehy (*Brit. Med. Jour.,* November 18, 1916) states that in every suspected case of this disease lumbar puncture should be performed at once, since it is impossible to make an accurate diagnosis without its aid. Cloudiness or turbidity of the fluid may be due to slight contamination with red blood cells, and this is the commonest source of error when the diagnosis is made primarily on the gross appearance of the fluid. The fluid should then be examined at once before centrifugation and again after sedimentation or centrifugation. The presence of appreciable numbers of polymorphonuclear leucocytes is a positive indication of an acute meningitis, but does not show the type. Cocci can often be seen in such fresh smears and add to the probability of the disease being meningococcal. The presence of fibrin should next be noted and the globulin content roughly determined by the ammonium sulphate ring test. Then the permanganate test should be applied. Cultures should be made to isolate the organism, and for the purpose of increasing the proportion of positive cultures the best plan is to incubate the spinal fluid alone for twenty-four hours before sowing it. The tests mentioned, other than the cultures, are scarcely necessary in the face of a definitely purulent fluid, but the potassium permanganate test may be employed in a roughly quantitative manner and then serves as an index of prognosis. In the very serious cases permanganate may be added to the amount of seven to ten times the volume of the spinal fluid before reduction ceases to occur.

Natural History of Septic Wounds.—Kenneth Goadby (*Lancet,* November 18, 1916) reports that an extensive study of the infected wounds of military practice has taught him that these differ considerably from those encountered in civil practice. In the first place the damage done the tissues about the gross wound is extensive in the case of the high velocity missiles and greatly militates against prompt reaction to infection. Repair and degenerative processes occur simultaneously in the different portions of such wounds, the former usually being in the more superficial layers, the latter in the deeper tissues which have been damaged, though not visibly so. The degenerative processes taking place in the depths of such wounds are commonly associated with infection by Bacillus perfringens, Bacillus malignant edema, or Bacillus hibler IX. The growth of these anaerobes is associated with direct tissue digestion, and the production of acids by these organisms also plays an important role in the determination of gas gangrene. The leucocytic reactions, both local in the wound and general in the blood, are influenced very largely by the degree of infection with the ordinary pathogenic cocci. Thus, about these there is marked accumulation of polymorphonuclear leucocytes, while about the region infected with one or another of the anaerobes the predominating cell is the lymphocyte. The leucocytosis in the blood is made high by the anaerobic organisms which also raise the proportion of polymorphonuclears.

Blood Pressure in Typhoid and Paratyphoid Fevers.—D. Olmer and R. Voisin (*Bulletins et mémoires de la Société médicale des hôpitaux de Paris,* July 27, 1916), from observations in seventy-six cases, assert that diminution of the arterial pressure, especially the diastolic pressure, in the typhoid affections, is so constant as to be of diagnostic value in some instances. In the presence of a typhoid condition, a marked fall in pressure, especially the systolic pressure, generally presages some complication and leads one to apprehend weakening of the myocardium. A sudden rise in pressure, on the other hand, may indicate an imminent intestinal hemorrhage, or, if defervescence has already occurred, a relapse. Where the pulse weakens in typhoid fever, prognostic and therapeutic indications should be sought in blood pressure examinations. Beside the cases complicated with myocarditis there occur hypotensive forms of the disease, running a latent course, without high fever, apparent complications, or alterations in the pulse rate or rhythm. These cases should be carefully watched, as they are the ones in which the patient is most exposed to sudden death. They constitute an incomplete syndrome of adrenal insufficiency, and the observation of a marked descent in blood pressure indicates treatment with adrenal gland or adrenaline. Subcutaneous injections of 0.00025 gram of the latter are of the greatest value in urgent cases, but oral ingestion of twenty or thirty drops of a one in one thousand solution is also effective. In two illustrative instances the systolic pressures rose from 100 and 105 mm. Hg., respectively, to 125 and 150 mm. Hg. in one and a half hour after subcutaneous injection of 0.00025 gram of adrenaline; the diastolic pressures in both cases rose from 50 to 55 mm. Hg.

Proceedings of National and Local Societies

NEW YORK NEUROLOGICAL SOCIETY.

The 349th Regular Meeting, Held at the New York Academy of Medicine, Tuesday, November 14, 1916, at 8.30 p. m.

Dr. WILLIAM M. LESZYNSKY in the Chair.

President's Address.—Dr. W. M. LESZYNSKY said that a committee of the society, consisting of Dr. Frederick Tilney, Dr. B. Sachs, Dr. C. L. Dana, Dr. W. Timme, and the speaker, was appointed in October, 1916, to ascertain the general plan and scope of the management of the recent epidemic of poliomyelitis, and the various clinics where these patients were receiving treatment had been visited. One large orthopedic clinic was found to have a special department, but the facilities and equipment were inadequate, owing to insufficient funds. At another the poliomyelitis cases were treated in the general clinic. At a third a special department had been organized with elaborate equipment. In the first, where 200 patients were treated by braces and massage, no neurological observations were made; in the second, where 300 patients were recorded, the treatment consisted of social service, braces, and massage, and though the disease was considered surgical, the aid of neurologists was welcomed; in the third 200 children received electrical examination, baking, massage, electrical treatment, braces when required, and muscle training, but there was no neurological supervision. At Bellevue Hospital and Cornell Medical School they were under the cooperative care of the neurologist and orthopedic surgeon. At Mt. Sinai and the Neurological Institute they were under the direct supervision of the neurologist. At all other dispensaries where these patients were received, they were sent to the orthopedic department.

As a result of these inquiries and for the purpose of expressing the views of the neurologists as to the best management, observation, and treatment of this type of disease affecting the nervous system, the meeting would be devoted to addresses and to discussion of the subject.

Through lack of foresight in the management of the recent epidemic, an unprecedented opportunity for clinical neurological observation was irretrievably lost. The value of cooperative neurological study was entirely forgotten or ignored. This was shown unquestionably by the New York health department suggesting or requesting the cooperation of neurologists, and by the omission of the names of neurologists from the lists of committees appointed, either by the city administration, or among those announced as the Committee on the Aftercare of Infantile Paralysis Cases, which was formed last August. There were twenty-five physicians on this list and of the three neurologists one was appointed four weeks ago, one was not aware of his membership, and the third merely had the privilege of attending the meetings of the committee.

Furthermore, the health department issued printed instructions with lists of hospitals and dispensaries where only orthopedic treatment could be obtained. Hence the entire supervision and control of these patients had been officially relegated to orthopedic institutions.

It was universally admitted that poliomyelitis was practically confined to the central nervous system, that its symptomatology, such as paralysis, atrophy, and trophic changes, was due to a spinal cord lesion, and that its infectious origin had no direct bearing upon the subsequent developments. Therefore, in the modern classification of disease, poliomyelitis had heretofore been assigned to the province of neurology. That the orthopedic institutions were placed in exclusive charge of the aftercare of these patients might have been more a matter of expediency than of medical selection or preference.

In the solution of a therapeutic proposition of this magnitude, standardization of treatment should be adapted to individual requirements, and the best interests of these patients would be conserved and scientific progress be promoted by the harmonious cooperation of the orthopedic surgeon with the neurologist and pediatrist. The disabled children should have every advantage that might develop from such associated service, and all available means should be used for their benefit.

Some Points in the Diagnosis and Treatment of Poliomyelitis.—This paper, by Dr. B. SACHS, appears on page 1225 of this issue of the JOURNAL.

The Present Management of Poliomyelitis in New York City.—This paper, by Dr. FREDERICK TILNEY, will be found on page 1221 of this issue of the JOURNAL.

Resolutions Concerning Poliomyelitis. — Dr. WALTER TIMME read the following resolutions adopted by the society:

Whereas, Anterior poliomyelitis and its concomitant polioencephalitis were intrinsically neurological diseases, and

Whereas, Anterior poliomyelitis and polioencephalitis had been managed in all stages in the recent epidemic practically without the supervision and control of neurologists in the institutions of greater New York, and

Whereas, Faulty diagnosis, inadequate treatment, and poor methods of gathering important statistics resulted not only in detriment to the present patients but also in a final loss to scientific medicine of valuable data of great service in future epidemics; it was

Resolved, That it was the sense of the New York Neurological Society that anterior poliomyelitis and polioencephalitis being neurological diseases, the sufferers from such diseases ought at an early period to come under the care or supervision of neurologists, with the cooperation of orthopedists, and other specialists as the cases might require. And, in consideration of the unprecedented number of cases in the recent epidemic, in all public institutions and clinics where these diseases were treated, there should be a standardization of equipment and method. And it was further

Resolved, That the New York Neurological Society petition the Committee on Public Health of

the New York Academy of Medicine that it consider the advisability of appointing at once a commission on poliomyelitis which should take into consideration the ways and means best calculated to meet and combat a future epidemic similar to the one just experienced and make definite recommendations. This commission should consist of four subcommittees as follows:

1. A committee on communicability and quarantine comprised of bacteriologists and epidemiologists.

2. A committee on the criteria of diagnosis and clinical management to consist of neurologists, pediatrists, and orthopedists.

3. A committee on pathology and serology to consist of pathologists who should devise the best means of caring for such pathological material as was obtained as a result of the epidemic.

4. A committee on treatment and immunization to consist of neurologists, orthopedists, pediatrists, and bacteriologists. This committee should consider the therapeutic means best adapted to the acute stage and also the aftertreatment.

Dr. Charles L. Dana said that with regard to the general management of the late epidemic it was only fair to remember that nobody knew exactly what to do at its inception. He thought that the authorities did the best they knew, acting on the best advice they could get. They made some mistakes and one was undoubtedly that of ignoring the work and possible help of neurology. It was not now too late to introduce this service for the therapeutic work since the victims of this epidemic would require treatment for a long time.

The public and perhaps some of the faculty did not realize that a considerable percentage of these victims would not need much treatment any way. They had had the infection, but no, or very slight, paralysis, and promptly got well. Another percentage of the cases, those with single and moderate paralysis involving only one segment of one limb, did not require elaborate treatment or the cooperation of specialists. Most of them improved under simple treatment. There was another and small percentage of cases in which the patients suffered severely, having quadriplegic and triplegic paralysis often with involvement of the trunk. These required the most careful supervision and humane attendance, but were hopeless so far as cure was concerned. There was a fourth group of cases which included thirty or forty per cent. of the whole, in which the paralyses were of considerable or moderate severity and distribution. These were cases in which the very best treatment of every possible kind should be employed. It was this phase of the question that was largely being debated tonight.

There were two phases of the subject to be considered: 1. The general management and organization of the institutions and individuals concerned in treatment and, 2, the technical methods of treatment. With regard to the first, the New York Committee on Aftercare of Infantile Paralysis Cases was working earnestly and would undoubtedly gradually bring matters into an efficient state. In regard to treatment, every one agreed that warm baths, exercises, muscle training, and educational methods in general were definitely helpful. Some doubted the value of electricity, others acclaimed it. The speaker was not expressing his opinion, but rather his experience when he said that it was definitely helpful in properly selected cases, and he considered it not only wrong but rather thoughtless to take the position that it was always useless, even when properly applied. He had never seen any direct benefit from massage, but thought it might be useful indirectly if done carefully.

There was no question of the value of warmth or of the utility of exercising in warm baths. The same was true of the measures which gave support to the paralyzed muscles by approximating the ends and relieving tension. There was a distinct difference of opinion between some neurologists and some orthopedists as to how much support by braces should be given and as to its extent and duration. Neurologists believed in allowing as much as possible normal physiological movements, allowing the child to lie on the bed or the floor and kick about rather than to lock up the joints in positions of perfect anatomical adjustment. Practically, however, there was never any difference of opinion when it came to individual cases between himself and the orthopedist.

Referring to prognosis, a physiological fact, perhaps not generally known, but of hopeful significance, was that the motor cells of the spinal cord increased in number from birth to adult life. Kaiser showed that in the anterior horn of the spinal cord at the time of birth there were about one hundred thousand cells and at the age of fifteen years two hundred thousand cells. This did not mean that nerve cells actually divided and multiplied, but that minute nucleated nerve cells developed into full sized function cells. Thus there was always hope in young children that nature was going to assist enormously the work of the therapeutist. It was better to take the position that all these therapeutic measures be allowed under wise supervision. No one knew enough to stand up and declare that massage was of no use, electricity was of no use, vibration was of no use, or braces were of no use. This attitude would be unjust to the child and to their art. The essential thing was a sane judgment of what should be used in each case. One thing only was absolutely certain: good came from wisely applied treatment and bad came from neglect or stupid and unintelligent treatment, whether this was boluses or braces. It was certain also that the general profession which both looked on and took part in this discussion would eventually pass final judgment, and care of poliomyelitis would be taken to or stay with the pediatrist, the neurologist, or the orthopedist, in accordance with the final test of experience. Cases should be assorted to each department in accordance with individual indications and the stage of the disease. But now, while waiting, it was only wise for the neurologists to urge upon those who had authority in dispensary therapeutics, that the child be given all the measures known to be probably helpful when wisely applied, and surely this meant that they should secure the cooperation of good and soundly grounded neurol-

ogists trained in dealing with paralyses, familiar with the anatomy and physiology of the disease, and able to give help in diagnosis and prognosis as well as in therapeutics. The qualification "good" was made because of the neurologist who dealt with the delicate mechanisms of the soul as well as of the body; it was especially true what Horace had said of poets and poetry; in some specialties mediocrity and tolerable endowments might properly be allowed, but neither gods nor men gave any indulgence to mediocre neurologists.

Dr. M. Allen Starr approved every suggestion made by Doctor Tilney and Doctor Sachs. In treating poliomyelitis they should not be confined to any one method; every known therapeutic measure should be resorted to. He was in favor of electrical treatment, though not of its unintelligent and indiscriminate use, but it was invaluable for exercising a muscle which could not be exercised by will. Many children had lost the power of voluntary muscular movement, and it was the duty of the attending physician to see that these muscles were exercised by electrical current for at least two years after onset, and galvanism only should be used. The sinusoidal current was the most efficacious. It could be given by any one properly trained; six careful lessons to any intelligent mother would enable her successfully to use a small galvanic battery of thirty cells. In the tenements and among people of mediocre intelligence those caring for the child could not be trusted and it would have to be brought to the clinics. The idea of visiting nurses was to be applauded in directing massage, proper bathing, electrical applications, and educational exercise; those who were contributing money for this purpose should be commended by the medical profession.

The next point of interest was in regard to graduated exercises under proper supervision. When Doctor Fraenkel gave instructions some time ago in regard to a carefully regulated series of movements which were beneficial in locomotor ataxia, the result was good; but when the matter was left in the hands of the patients alone they lost interest and found the continuance of the movements monotonous. When a trained instructor went to the patient day after day and helped and encouraged him, the results were remarkable. With education of muscles and exercise it was necessary to have an instructor who was capable; some one who understood it and carried it out with the cooperation of the patient. Massage could be done by the mother. The Zander movements were also important. All these measures could be applied at the clinics or by a nurse at home.

Out of 404 cases of infantile paralysis in the epidemic of 1907, in 280 one or both legs were affected; in eighty-four the arm, and in forty the neck and face. Orthopedic apparatus could have been put on 280, but there remained 124 where orthopedics were of no avail whatever. Orthopedics strengthened a leg, but there were many cases not open to orthopedic treatment, and this the public did not understand. Large amounts of money were being used to buy braces; in fact the mind of the public seemed to be focused on braces. Apparatus was valuable to keep a limb in proper position, but a brace which kept a child from exercising its limb did harm instead of good. Braces should be removed occasionally and not kept on all the time.

Dr. Edward D. Fisher said that there was no antagonism between orthopedists and neurologists apparent to him. He had seen many of these cases during the summer and any neurologist could also have seen as many as he wished. In regard to treatment, certainly neurology had nothing to do with the early stage. Etiology belonged to the laboratory and, if possible, a remedy, either for prevention or cure. The health department had worked faithfully on these lines. It was with the future of these children that what had been said by Doctor Tilney and Doctor Sachs applied. Any one with experience in this disease must agree to this. There was a distinction between the treatment of the orthopedist and neurologist, and there should always be cooperation between them.

Dr. Virgil P. Gibney, as an orthopedist among so many neurologists, felt out of place. But while he was listening to the criticism he was reminded of the story of the young man who went out and committed suicide by hanging. Some one asked why and was told that he had done it because he had been criticised. If that was a good reason, said the curious one, then the woods would be full of doctors, lawyers, clergymen, artists, and others hanging from the trees; if a professional man was not criticised, he would do well to commit suicide, as he was a dead one already. For thirteen years the speaker was an intern at the Hospital for the Relief of the Ruptured and Crippled; here he employed galvanism, faradism, and franklinic electricity in infantile paralysis, day in and day out; many cases were recent, but the majority were of patients who had been paralyzed from one to four or five years. He measured the limbs from time to time and kept full records, but was unable to see that electricity in any form helped except in diagnosis; he learned early that by galvanism a fair test could be made, but as far as treatment was concerned it yielded no permanent results. Doctor Gibney said that he had referred many cases of poliomyelitis to neurologists for their opinion and had carried out their treatment faithfully, but had come to the conclusion that electricity was valuable only in diagnosis.

The speaker agreed with Doctor Dana in believing that nothing should be omitted that would give hope of recovery or relief from pain or deformity; he used braces that could be taken off, put the patient in warm baths, and moved the limbs from time to time. After deformity had been corrected and the muscles were capable of support, the apparatus was discarded until deformity recurred. Although they were called orthopedic surgeons, they practised neurology as did the neurologists. If the neurologists proposed to work with orthopedists, they would find no methods of treatment opposing them.

In reply to Doctor Starr's remark about braces not being applicable to the upper extremities, he would reply that he had had occasions to adjust apparatus to give rest to the deltoid and relieve it

of strain. This consisted of a brace with arm pieces to keep the arm and forearm in extension above the head or at right angles from the side. He was sure that neurologists would agree with him that paralysis of the deltoid on one or both sides was of frequent occurrence in the recent epidemic. The muscles must not be overtired or overexercised; when the muscle was weak it should be supported and joints should be protected from strain and consequent relaxation. Deformity should be corrected, but it took from one to two years for the muscles to regain strength and tone. In spite of treatment, many cases from the 1907 epidemic were still *in statu quo ante* and were in the hospital for orthopedic surgical operations; they all had had electricity, massage, and apparatus. The present epidemic was the worst experienced and in the aftermath the neurologists would find that the orthopedic men were willing to cooperate in every way.

Dr. Reginald H. Sayre said that orthopedics had been defined by Audry, who first used the term to describe the art of correcting or preventing deformities in children. It seemed to be taken for granted that an orthopedist tied the patient up in an apparatus and left to the Almighty any other improvement, taking no other therapeutic measures. He wished to assure the neurologists that they were mistaken, as orthopedists used every known measure of cure or relief.

Dr. Arthur H. Cilley would like to know whether the strictures laid on the health department in not consulting the neurologists were well taken. Was it a fact that any neurologist had offered his services to the health department and been refused? The speaker knew personally of only one volunteer, an orthopedist, whose services were quickly accepted, and he personally had approached two neurologists to offer them a share in the work. Their reply was that Riverside Hospital was too far away.

Dr. William M. Leszynsky, in answer to Doctor Cilley's questions, wished to say that the statements made this evening were done so deliberately, being founded on facts and based on thorough investigation.

MEDICAL SOCIETY OF THE STATE OF NEW YORK.

Stated Meeting, Held November 23, 1916.

COMMITTEE ON MEDICAL ECONOMICS.

(*Concluded from page 1215.*)

Compulsory Health Insurance (*Continued*).—In the plan outlined by Doctor Kopetzky, the medical referee was a physician as well trained in medicine and surgery as in health matters. He was to be paid by the Mutual Funds and under control of the Mutual Funds, but would have absolutely nothing to do with private practice or the care of patients in any way. Half of the directors who would control and manage the Mutual Funds would be appointees of the employers, and half appointees of the working man. In that way the referee would be responsible to both sides equally; he would not be interested in any controversy and would have nothing whatever to do with the care of patients. All referees should be appointees and officers from the executive departments. They would be administrative officers and the ideal referees would be those appointed by the State as part of the regular administration of the law. This, at present, under the exigencies of politics, might not be feasible in this State. In Doctor Kopetzky's outline, therefore, it was put according to standards set by the medical advisory board. The State Civil Service Board examined the medical referees and they were chosen by the directorate of the Mutual Fund. But the every day care of the patient was divorced from them which could not be reiterated too strongly as the necessary condition.

Another thing that was inherently wrong in the English health insurance was that all men were paid on the capitation basis. That was lodge practice developed to the nth power. There were certain inherent evils in capitation which could not be ameliorated. Briefly the speaker's present opinion was that the payment of physicians should be a matter of executive regulation under the commissioners and not part of organic law. The plan outlined by Doctor Kopetzky was designed to be put in the organic law. It would be difficult to change because it would be necessary to have legislative action to change it. Executive regulations were easily changed and justice could be more easily obtained and injustice more easily remedied. Therefore, medical regulations and all regulations concerning the daily care of the patient should be under executive regulation and not under organic law.

Dr. Emil Altman said there was no one scheme that would please everybody. In the same way that one safeguarded one's property rights, this committee had sought to establish a bill that would safeguard the health of the working man and his wages in such form as to satisfy everybody, but this could not be done, there were so many objections. There was only one thing to be kept in view in passing on a measure of this kind, and that was the greatest good of the greatest number. This measure was not entirely altruistic, but it should not be considered from a money standpoint only.

The speaker wished to take issue with Doctor Warren's suggestion that public health officials had a monopoly on knowledge of sanitation, because any practitioner could acquire it with a little training. They had more experience, of course, with epidemic disease and preventive measures. But the fact that a public health officer was sure of his pay for his services did not always make him ready to demonstrate his professional skill, as was shown recently when they were called upon to examine some of the working people in their department without extra compensation. Their desire was to be of benefit to humanity, but they did not include the poor working class.

Alfred E. Ommen, Esq., ex-judge and ex-president of the Society of Medical Jurisprudence, said that as the meeting had heard the subject discussed from various angles, those of the doctor, the working man, and the insurance carrier, he considered that it was about time somebody discussed it from the standpoint of the public. Doctor Delphey had

said that he thought every man, woman, and child should have free medical service under the State or Government whether they paid any part of the cost or not, on the same ground that the State furnished free schooling, free fire protection, and free water. There had been considerable applause when that statement was made, but analysis would show that in the city of New York it cost this year $45,000,000 for free schools, about $12,000,000 or more for free fire protection, and if one did not pay his water bill he would find that he could not get free water. Surely one did not want to class the medical profession with the firemen and policemen, existing only on money obtained from taxing the population.

Mr. Dawson had said that the bill would abolish patent medicines and quackery. The speaker declared that he did not think it would. Many physicians prescribed patent medicines because they contained in exact formula the medication considered advisable for the particular case and would probably always continue to do so. It was also a mistake to believe that this law would abolish dispensaries. There would always be rich people who felt that the poor were not getting proper attention by the paid doctors and that it was better to have dispensaries.

At a hearing on the Mills Health Insurance Bill, at Albany, where Doctor Kopetzky and the speaker were present, James P. Holland, president of the State Federation of Labor, asked by what right the American Association for Labor Legislation used the word "labor" and who had given them authority to do so, as this association did not represent labor and labor was opposed to the Mills bill. The speaker's understanding of labor's point of view in the matter of compulsory health insurance was that it was willing to benefit by it provided that all the expenses in connection with it were paid by the employer and the State and not any expense whatever by labor. Also, that if labor ultimately did decide to pay any part of the expense, it would not permit a deduction of its share to be made from the weekly payroll as provided in the Mills bill.

The entire proposition tended toward State socialism. The time had come when everything tended to be regulated by law; there were laws now when certain people should get up and when they should go to bed; when they should eat and what they should eat. A lot of this propaganda came from social workers and so called uplifters, who had no interest in the thing whatever and not a dollar invested, but were always telling other people how to live and act and have their being.

The individual should be allowed to live his own life and build up his own character. This bill might be temporarily beneficial to the young doctor just coming out of medical school, as he would receive a fixed salary and have immediately an established income, but it would not help the general medical profession. Men developed the best in them through the battle of life. Knowledge of prophylaxis and therapeutics would be discouraged in young doctors, and probably the career of many a competent young man would be checked who if he had to open an office for himself and establish a practice would some day become a great physician. It was not suitable that the medical profession generally become salaried employees of the State or of any associations created for that purpose.

Dr. Samuel A. Tannenbaum said that inasmuch as compulsory health insurance was inevitable, the medical profession should not oppose, but welcome it, and try to get the most out of it for the benefit of the public as well as the profession. Labor was at present opposed because it distrusted the insurance companies, and because it was already getting free medical services in dispensaries and hospitals and from lodge doctors, and because labor had not risen to the dignity of refusing to be treated as a pauper.

Dr. H. L. Winter, of Cornwall, N. Y., said that it was the general impression among physicians throughout the State that some form of State medicine was inevitable. Whether it would take the form proposed in the present tentative bill for health insurance or not, however, was a question which required further time to decide. There was one thing certain, and that was that none of these bills should become a law until the matter of compensation had been decided as satisfactorily as possible to the medical profession. The speaker had the honor to be a member of the Council of the State Society at the time the Workman's Compensation Law went into effect. While a so called tentative fee bill was submitted to the members, they had practically nothing to say about the fees which were to be allowed for medical services. Whether the bill was satisfactory or not, it was the principle involved that counted.

Dr. William S. Gottheil thought it is the greatest pity in the world that Mr. Frayne was not present, because they were all interested in the medical details, and wanted a square deal for the doctor. He thought the fundamental question whether the people wanted a bill of this kind or not was one that interested them still more. If the labor interests and the interests that controlled the votes did not want a compulsory health insurance law, then the gentlemen of the A. A. L. L. had given the administration a great deal of vicious trouble. Some of them had given much time, care, and attention to these medical details and would like to know whether the bill was wanted or not. The object was to see that if a health insurance bill was passed, the doctors received fair treatment. They were going to do decent work without the supervision of the local health insurance officers or the State insurance officers, and he was not much interested in the individual schemes so long as whatever plan was selected was an equitable one. He did not know whether "capitation" or "visitation" was the most desirable method of compensation. They had not yet been able to decide that question, but he did know that the demands, or rather the postulates, which Doctor Delphey had stated in his paper were the ones that they must stand by. They must be in any bill that was to be presented if it was to have the support of the Legislature, because they did not propose to push this or any other. The postulates were those of proper representation on the commission, etc., formation of panels, free choice of doctors, and especially the collective bargaining which was, to the speaker's mind, the basis of anything like a just and

equitable agreement between the insurers and the physicians.

In the present instance, the backers of the proposed health insurance wished to give the medical profession every chance, and it would be their own fault if they did not take it. The Committee on Economics of the State Society was doing excellent work and was taking the matter up in the right way by giving it wide publicity from every side. It was, however, impossible for such a committee to do satisfactory work without assistance and the subject should be referred to every county society in the State for free discussion before any steps towards legislation were taken.

Everyone interested in the subject should move slowly and every means should be taken to prevent an inefficient or incomplete bill being presented to the Legislature.

Letters to the Editors

SOME RESULTS OF BIRTH CONTROL.

To the Editors: New York, *December 13, 1916.*

Since the publication of my article on Birth Control in the issue of your esteemed Journal for November 18th, I have been the recipient of many letters from readers of the Journal, a good number commenting favorably on my attitude toward this difficult problem, a few condemning it, saying that it was an economic and not at all a medical question, and lastly, some criticising me kindly on the incompleteness of my contribution.

To those whose criticisms and condemnations of my attitude were rather of a private nature I replied privately, and I hope satisfactorily. To the critics who maintain that with the knowledge of birth limitation many women, whether poor or rich, who should and can bear children, will shirk the duties of motherhood, I wish to reply that I do not believe this. In fact, I feel most certain that it is not true, and I would like to tell my friends that one can no more prevent the desire for motherhood in the normal, healthy woman than one can stem the tide of the ocean. It is inherent in every woman's heart. With more marriages of young people and a rational birth control, I do believe there will not be fewer children, but the same number of better ones. There will be, of course, instances—and there are too many in certain classes of society now—where for purely selfish reasons the marriage remains barren, but it is a question in my mind whether it would be really desirable for society to have such women be mothers.

Again it has been asserted that the enfeebled, diseased, ignorant, and poverty stricken woman in whose case birth control might be justified, will never know about the existence of birth control clinics. In Holland however, there must have been some such ignorant women, yet they seemed to have learned to avail themselves of the service of such clinics. Besides, these classes will sooner or later come under the observation of some physician, either privately or in a hospital. Some opponents to the birth control propaganda say that the measure advocated would not reach the feebleminded, the idiotic, half insane, chronic alcoholics, and chronic criminals. This I will grant, and sterilization of those totally unfit for parenthood will some day have to become a State measure unless segregation is resorted to more universally and more rigorously. Birth control is only one measure toward a saner and happier manhood, womanhood, and childhood.

Finally, I must reply to the almost pathetic criticisms of those of my colleagues who wrote me that this matter was a question not for the medical profession, but for the laity. To such I could only express my regret at their attitude. The physician of the twentieth century who deals only with the purely medical and curative part of his profession, who is indifferent to the measures to prevent disease, and cannot feel with the social sufferings of the masses, is lacking in the highest ideals of his calling and misses the greatest opportunity of benefiting suffering mankind.

S. Adolphus Knopf, M. D.

Book Reviews

[We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.]

Medical Lectures and Aphorisms. By Samuel Gee, M. D., Fellow of the Royal College of Physicians, Honorary Physician to H. R. H. The Prince of Wales, and Consulting Physician to St. Bartholomew's Hospital. With Recollections by J. Wickham Legg. London: Henry Frowde (Oxford University Press) and Hodder & Stoughton, 1915. Pp. viii-408. (Price, $2.)

It is a rare pleasure and privilege to have a book of this kind drop into the editorial hands. Fascinating as are the bare facts of medical science, they are as susceptible as other facts to artistic literary treatment, and to acquire thereby additional charm and interest. Fortunate indeed were the students whose first knowledge of the subjects treated in this volume was acquired from the genial and scholarly author; the hours must have sped by quickly and memory must have hardly been aware of a burden as it treasured up the musical sentences in which were embodied the personal experiences that doubtless added much to the dryer details which had been long accumulating in the textbooks. The subjects cover a fairly wide range, beginning with the history of a case of cerebral hemorrhage, going on to brachycephalic and dolichocephalic heads, to catarrh and bronchitis, asthma, enlarged spleen, tuberculous peritonitis, etc. There is a discussion of sects in medicine, and finally a delightful series of clinical aphorisms, 272 in number, each a medical epigram worthy to be pondered. The volume concludes with Recollections of Samuel Gee, by J. Wickham Legg, Hon. D. Litt. (Oxon.), F. S. A. (Lond.), which will well repay perusal. We cannot resist stating, in commending this interesting work to our friends and readers, that it is an excellent book by Gee!

Geschichte der Augenheilkunde. Von Dr. J. Hirschberg, Professor in Berlin. Drittes Buch, Dreizehnter Abschnitt. Die Augenärzte der Schweiz, 1800 bis 1875. Mit 5 Figuren im Text. (Handbuch der Gesamten Augenheilkunde, 2. Aufl. XIV. Band, VII.) Leipzig: Wilhelm Engelmann, 1916. Pp. 273.

This is the third volume of a series entitled The History of Ophthalmology, published by Julius Hirschberg, M. D., of Berlin, on the occasion of the celebration of his jubilee. The foremost ophthalmologists of the different countries enumerated during the period from 1800 to 1875 are listed, together with a short biography and reference to their writings. There is a separate chapter for each country containing two indexes, one for the subject matter and the other for the authors of the different articles. The work is exhaustive and, together with the remaining volumes, forms a complete history of ophthalmology during this period.

Mortality Statistics, 1914. Department of Commerce. Bureau of the Census. Sam L. Rogers, Director. Fifteenth Annual Report. Washington: Government Printing Office, 1916. Pp. 714.

The fifteenth annual report of the census bureau is a compilation of the mortality statistics for 1914, covering the registration area of the United States. The number of deaths registered was 838,059, corresponding to a death rate of 13.6 per 1,000 population, the lowest ever recorded for the registration area. The causes of death are based upon the International List of Causes of Death and the report contains complete summaries and rate tables. It is a valuable reference book for all those interested in the subject.

Proceedings of the American Medico-Psychological Association. Seventy-first Annual Meeting, held at Old Point Comfort, Va., May 11-14, 1915. Published by American Medico-Psychological Association. Pp. 387.

This volume, which has just come to hand, contains the representative work of the members of the medical profession who have to treat the vast majority of the mentally disordered in this country, and naturally contains much valuable matter, from administrative, diagnostic, and therapeutic viewpoints. If there is any fault in this collection of papers, it is in the conservative note struck; the

genetic and interpretative side of psychiatry is conspicuous by its absence. On the other hand, the management of mental cases *en masse* receives much attention—the occupation and recreation of the patients—and there is some discussion of such subjects as the treatment of paresis by the newer methods.

Cultivo in Vitro del Plasmodium vivax. Dr. JUAN ITURBE, Miembro de la Academia de Medicina. Dr. EUDORO GONZÁLEZ, Laboratorio Del Dr. Juan Iturbe. Caracas, Venezuela, 1916.

This little brochure describes the authors' experience in the artificial cultivation of Plasmodium vivax after the method of Bass. This method was greatly simplified so as to be readily utilizable in any laboratory. Ten c. c. of defibrinated blood were mixed with ten cgm. of a fifty per cent. solution of dextrose, placed in tubes each containing three c. c., and used as a culture medium. Centrifugation was unnecessary, and the sporulation cycle of the parasite was found to be shortened in proportion to the elevation of temperature, it being only thirty-two hours at 41° C.

Contribución al estudio de los gérmenes patógenos del agua. Dr. JUAN ITURBE, Miembro de la Academia de Medicina. Dr. EUDORO GONZÁLEZ. Caracas, 1916.

This pamphlet gives the results of the examination of thirty-four samples of water taken from various parts of the city of Caracas in a search for bacteria of the typhoid and colon group.

El Paludismo De Las Aves En Venezuela. Dr. JUAN ITURBE, Miembro de la Academia de Medicina. Dr. EUDORO GONZÁLEZ. Caracas-Venezuela, 1916.

Hæmoproteus danilewsky was found by these investigators in 145 of 367 specimens of Venezuelan birds whose blood they examined. Rosenbusch's method of fixation and staining was used throughout by them with uniform satisfaction.

Interclinical Notes

A good joke is probably immortal. On page 844 of the *Outlook* for December 20th is a cartoon from the London *Bystander*, showing an officer on a battleship conversing with a recently acquired midshipman. The officer remarks politely, "Well, my boy, the old story, I suppose—the fool of the family sent to sea?" To which the boy rejoins, "Oh, no sir; that's all changed since your day." This wheeze, practically unaltered, occurs in one of Captain Marryat's best sea stories written about one hundred years ago.

* * *

The *Survey* for December 2nd gives a list of bills to be presented to the sixty-fourth Congress dealing with social hygiene—labor, health, and immigration Several of these bills have been approved by labor. One is a bill to promote efficiency in the public health service. It provides for the appointment of a surgeon general who has been trained in national health administration as well as in hygiene and disease prevention; secures a permanent position for that officer in the service at the expiration of his term of office; simplifies the promotion of assistant surgeons, and makes possible the appointment of five additional professors.

* * *

Do our readers know what Naval Stores are? They would if they had read in *Commerce and Finance* for December 6th an article on the subject by E. S. Nash. Naval Stores are nothing more or less than the products of the pine tree, tar and pitch, once extensively used in the navy for smearing ropes and caulking the seams of ships. As our ships are now of steel, turpentine and rosin have had to find a market elsewhere, but soap makers (and some ointment makers, very likely), paper manufacturers, makers of varnish, paint, and russet shoe polish absorb the supply nowadays. No doubt, too, the now numerous students of the violin account for considerable rosin.

* * *

"Bible!" exclaims *Leslie's* for December 14th. "Thirty Bible societies throughout the world put into circulation annually about 18,000,000 copies of the Holy Scriptures. When to this is added 10,000,000 more, the output of private publishing houses it is readily seen that the Bible is entitled to be called the world's "best seller." It pays to advertise, however, even the sacred scriptures, so the New York Bible Society urged the second Sunday in Advent—this year December 10th—as Universal Bible Sunday." Far be it from us to criticise statements concerning the circulation of the English Bible, but we recently saw forty-five copies of the volume in the cupboard off a bedroom in a big uptown hotel. Perhaps an excessively impious guest had once occupied that room, who needed all that weight of sacred literature to balance his villainy. It is more likely, however, that the system of distribution had broken down at some point.

* * *

Stefansson, the arctic explorer, according to the *Outlook* for December 6th, considers Broadway to be more dangerous than the average trail near the north pole. When his fear of Broadway was commented upon he is reported to have answered: "The streets of New York are more dangerous than the frozen level plains of the Arctic Ocean. In the north, ice can be measured, meteorological conditions studied, and the extent and the imminence of most dangers can generally be determined pretty accurately. But on these streets danger is at every hand and cannot be foreseen. While avoiding a taxicab you step into a subway excavation, and in sidestepping a motor truck you walk under a falling piano."

Meetings of Local Medical Societies

TUESDAY, *December 26th.*—New York Academy of Medicine (Section in Obstetrics and Gynecology); New York Dermatological Society; Metropolitan Medical Society of New York City (annual); Buffalo Academy of Medicine; New York Medical Union; New York City Riverside Practitioners' Society; Washington Heights Medical Society; Woman's Hospital Society, New York; Therapeutic Club, New York; Valentine Mott Medical Society, New York; Onondaga Medical Society (annual).

WEDNESDAY, *December 27th.*—New York Academy of Medicine (Section in Laryngology and Rhinology); New York Society of Internal Medicine; Schenectady Academy of Medicine.

THURSDAY, *December 28th.*—New York Physicians' Association (annual); Hospital Graduates' Club, New York; Medical Union, Buffalo; Ex-Intern Society of Seney Hospital, Brooklyn.

FRIDAY, *December 29th.*—Academy of Pathological Science, New York (annual); Hospital Graduates' Club, Brooklyn.

Official News

United States Public Health Service:

Official list of changes in the stations and duties of commissioned and other officers of the United States Public Health Service for the seven days ending December 13, 1916:

FRICKS, L. D., Surgeon. Reassigned to duty at the Hygienic Laboratory, Washington, D. C., effective December 5, 1916.

GOLDBERGER, JOSEPH, Surgeon. Reassigned to duty at the Hygienic Laboratory. Washington, D. C., effective October 31, 1916.

HARRINGTON, F. E., Assistant Epidemiologist. Directed to proceed to Anne Arundel and Dorchester Counties, Md., to make sanitary resurveys of those counties.

HASSELTINE, H. D., Passed Assistant Surgeon. Reassigned to duty at the Hygienic Laboratory, Washington, D. C., effective December 6, 1916.

IRWIN, FAIRFAX, Senior Surgeon. Granted twelve days' leave of absence from December 26, 1916.

KEMPF, G. A., Passed Assistant Surgeon. Reassigned to duty at Ellis Island Immigration Station, New York, effective August 17, 1916.

KOLB, Passed Assistant Surgeon. Granted one month's leave of absence from December 23, 1916.

LAUGHLIN, J. B., Assistant Surgeon. Directed to proceed to Talladega, Ala., to investigate the water supplied to passenger trains in interstate traffic.

Moore, Dunlop, Surgeon. Reassigned to duty at Ellis Island Immigration Station, New York, effective October 3, 1916.

Nydegger, J. A., Surgeon. Directed to proceed to Washington, D. C., for duty on the Board on Color Perception.

Oleson, Robert, Passed Assistant Surgeon. Directed to proceed to certain plants of the General Chemical Company, in connection with investigations of industrial sanitation.

Rucker, W. C., Assistant Surgeon General. Directed to proceed to Chicago, Ill., on business relative to the operation of the Interstate Sanitary District of the Great Lakes.

Smith, F. C., Surgeon. Detailed to deliver an address on public health at the meeting of the Seaboard Medical Association, Washington, N. C., December 19-21, 1916.

Williams, C. L., Passed Assistant Surgeon. Directed to proceed to various points in the State of California to conduct the work of the eradication of plague among ground squirrels.

Williams, L. L., Senior Surgeon. Directed to make a sanitary survey of Yosemite National Park.

United States Navy Intelligence:

Official list of changes in the stations and duties of officers serving in the Medical Corps of the United States Navy for the three weeks ending December 9, 1916:

Ames, M. H., Passed Assistant Surgeon. Detached from the *Salem* and ordered to the *Maine*.

Bacon, Sankey, Passed Assistant Surgeon. Detached from the *Panther*, and placed on waiting orders.

Brown, E. A., Assistant Surgeon. Commissioned an assistant surgeon, Medical Reserve Corps, from November 7, 1916.

Calver, G. W., Assistant Surgeon. Detached from the *Brooklyn* and ordered to the Yokohama Hospital for treatment.

Carr, E. C., Assistant Surgeon. Commissioned an assistant surgeon, Medical Reserve Corps, from November 7, 1916.

Casto, D. H., Passed Assistant Surgeon. Detached from the Marine Brigade, Port au Prince, Haiti, and placed on waiting orders.

Clement, M. T., Assistant Surgeon. Commissioned an assistant surgeon, Medical Reserve Corps, from November 7, 1916; ordered to the Marine Barracks, Port Royal, S. C.

Clerf, L. H., Assistant Surgeon. Commissioned an assistant surgeon, Medical Reserve Corps, from November 7; ordered to duty at the Naval Hospital, Great Lakes, Ill.

Cornett, H. V., Assistant Surgeon. Detached from the *Villalobos and* ordered to the Canacao Hospital.

Crawford, R. L., Assistant Surgeon Detached from the *Rhode Island* and ordered to the *Smith*.

Donelson, M., Passed Assistant Surgeon. Detached from the receiving ship at Norfolk, Va., and ordered to the *Pennsylvania*.

Dragoo, C. H., Passed Assistant Surgeon. Detached from the naval training station, Newport, R. I., and ordered to navy recruiting station, Detroit, Mich.

Durrett, J. H., Assistant Surgeon. Commissioned an assistant surgeon, Medical Reserve Corps, from November 7, 1916.

Farwell, W. G., Passed Assistant Surgeon. Ordered to the navy recruiting station, Brooklyn, N. Y.

Findeisen, W. L., Passed Assistant Surgeon. Detached from the navy recruiting station, Detroit, Mich., and ordered to the naval training station, Newport, R. I.

Foote, O. C, Assistant Surgeon. Detached from the *Delaware* and ordered to the *Sterett*.

Freeman, G. R., Surgeon. Ordered to Navy Yard, Boston, Mass.

Hetfield, W. B., Assistant Surgeon. Detached from the *Monocacy* and ordered to Olongapo, P. I.

Henry, R. B., Passed Assistant Surgeon. Ordered to the training station, Norfolk, Va.

Johnson, M. K., Surgeon. Detached from the *Oklahoma* and ordered home to await orders.

Kobbe, E. E., Assistant Surgeon. Commissioned an assistant surgeon, Medical Reserve Corps, from November 7, 1916.

Lawrence, H. F., Passed Assistant Surgeon. Detached from the Naval Hospital, New York, and ordered to duty with the Marine Expeditionary Forces, Santo Domingo.

Lowman, K. E., Assistant Surgeon. Commissioned an assistant surgeon, Medical Reserve Corps, from November 7, 1916.

McCullough, F. E., Surgeon. Detached from the *Florida* and ordered to the *Oklahoma*.

McDonell, W. N., Passed Assistant Surgeon. Detached from the *Pennsylvania* and ordered to the *Montana*.

McLean, N. T., Passed Assistant Surgeon. Ordered to Haiti, for duty as sanitary engineer.

O'Brien, C. S., Assistant Surgeon. Detached from the Canacao Hospital and ordered to the *Villalobos*.

Pollard, J. B., Passed Assistant Surgeon. Detached from Naval Academy, Annapolis, Md., and ordered to the Naval Hospital, Norfolk, Va.

Porter, F. E., Passed Assistant Surgeon. Detached from the *San Francisco* and placed on waiting orders; ordered to the navy recruiting station, Portland, Me.

Raison, T. W., Passed Assistant Surgeon. Detached from the Naval Hospital, Great Lakes, Ill., and ordered to duty with the Marine Expeditionary Force, Santo Domingo.

Rhoades, G. C., Passed Assistant Surgeon. Detached from the Naval Hospital, Norfolk, Va., and ordered to the *San Francisco*.

Robertson, G. E., Passed Assistant Surgeon. Detached from the *Memphis* and ordered to the *Arkansas*.

Robinson, A., Assistant Surgeon. Commissioned an assistant surgeon from November 4, 1916.

Sellers, F. E., Passed Assistant Surgeon. Detached from the *Kearsarge* and ordered to the *Panther*.

Smith, A. G., Assistant Surgeon. Commissioned an assistant surgeon, Medical Reserve Corps, from November 7, 1916; ordered to the Naval Hospital, New York.

Stalnaker, P. R., Passed Assistant Surgeon. Ordered to the training station, Newport, R. I.

Stein, E. J., Assistant Surgeon. Commissioned an assistant surgeon, Medical Reserve Corps, from November 7, 1916.

Sullivan, A. J., Assistant Surgeon. Commissioned an assistant surgeon from October 7, 1916.

Taylor, S. P., Jr., Assistant Surgeon. Commissioned an assistant surgeon from November 4, 1916.

Taylor, S. M., Assistant Surgeon. Detached from the Olongaco Hospital and ordered to the *Monocacy*.

Weaver, C. H., Assistant Surgeon. Detached from the *Arkansas* and ordered to the *Paducah*.

Wiggs, L. B., Assistant Surgeon. Ordered to naval recruiting station, Columbia, S. C.

Williams, R. B., Surgeon. Detached from duty with the Marine Expeditionary Forces, Haiti and ordered to the *Florida*.

Zalesky, W. J., Passed Assistant Surgeon. Detached from the naval recruiting station, Brooklyn, and ordered to the New York Naval Hospital.

Births, Marriages, and Deaths

Died.

Cain.—In Sewanee, Tenn., on Sunday, December 3rd, Dr. John Savely Cain, aged eighty-seven years.

Cohn.—In San Francisco, Cal., on Sunday, December 3rd, Dr. Isadore Elkan Cohn, aged sixty-four years.

Ernest.—In Lockport, N Y., on Tuesday, December 5th, Dr J. Glenn Ernest, aged forty-six years.

Huston.—In Hamilton, Ohio, on Tuesday, December 5th, Dr. William C. Huston, aged forty-eight years.

Le Fevre.—In Portland, Ore., on Saturday, December 2nd, Dr. Frank W. Le Fevre, aged fifty-seven years.

O'Neil.—In Providence, R. I., on Thursday December 7th, Dr John Edward O'Neil, aged fifty years.

Reamer.—In Baltimore, Md., on Monday, December 5th, Dr. Howard C. Reamer, of Danville, Cal., aged fifty years.

Richman.—In Philadelphia, Pa., on Friday, December 8th, Dr. Kenneth Charles Richman, aged thirty years.

Smith.—In Glenn Springs, S. C., on Sunday, December 3rd, Dr. William F. Smith, aged eighty-three years.

Williams.—In Mt. Carmel, Pa., on Sunday, December 3rd, Dr. Walter Lear Williams, aged thirty-seven years.

DENTAL INFECTIONS IN SYSTEMIC DISORDERS.*

Their Röntgenographic Diagnosis.

BY SINCLAIR TOUSEY, A.M., M.D.,
New York.

"The widest publicity should be given to the fact that greatly varying and sometimes serious or fatal systemic diseases and those affecting remote organs are often due to infection connected with the teeth or with the pneumatic sinuses of the face. The infected foci are discoverable by the x rays. Some of these cases are cured by treatment of the oral lesion and some require also autogenous vaccination with a bacterial culture from the pus in the oral lesion." These are the words of an eminent jurist whose wife has been dragged back from the verge of the grave through the discovery by the x rays of a focus of infection in connection with the teeth. Pernicious anemia and general spinal sclerosis were threatening to destroy life. The judge's remark is the occasion for this article.

INFECTIONS OF THE TEETH AND PNEUMATIC SINUSES AND X RAY DIAGNOSIS.

A. *Alveolar abscess.* This is the technical name given to infection about the apex of the root of a tooth with a certain amount of decalcification of bone, but not necessarily with liquid pus. The usual origin is from the death and putrefaction of the nerve or pulp of the tooth. The access of septic microorganisms to the region of the apical foramen is either along the root of the tooth or through the pores in the decayed tooth substance. The root canal once infected has no means of spontaneous cure. Its cavity cannot become obliterated by a process of granulation and cicatrization, but remains as a permanent culture chamber for the germs.

The most dangerous cases are those which develop insidiously, without pain, and whose existence is unknown to the patient and even to the dentist until the occurrence of some severe constitutional or other secondary disorder leads to their discovery by x ray examination. It might be expected from the absence of local symptoms that the x ray appearance in these insidious dental infections would be less striking than of those with pronounced local symptoms, but these are sometimes much more noticeable. Other cases pursue a perfectly frank and recognizable course. There is toothache followed by a painful swelling of the jaw. These cases naturally come for relief to the hands of the dentist, but if they are neglected, an abscess forms in the jawbone surrounding the apex of the root, denuding the latter and sometimes eroding it considerably. In some cases there is more or less necrosis of the jaw. All these conditions are clearly shown with almost microscopic detail in a radiograph. These obvious cases are treated by the dentist, who opens the pulp chamber, removes the nerve, and drains the abscess cavity through the root canal. When an aseptic condition has been secured, a radiographic figure with a wire in the root canal will show whether the foramen has been reached. The dentist then fills the root canal to the apex with nonabsorbent material. Some cases require amputation of the apex of the root. Only extreme cases require extraction of the tooth with or without curettage of necrotic bone.

Very many if not most of the cases of alveolar abscess referred for x ray examination are connected with teeth which have already gone through the history of death and removal of the nerve. The x ray often shows in such a case that the root canal has been only partly filled. A cavity remains in the tooth, lodging germs which keep up infection of the jaw and the general system and on occasion start an abscess in the jaw bone.

Pyorrhœa alveolaris, also called Riggs's disease. This is a disease the symptoms of which point directly to the teeth, and which the dentist is naturally called upon to treat. The name implies a discharge of pus from the alveolus or tooth socket. The gums around certain individual teeth are swollen and usually red and bleeding, but sometimes white and cartilaginous. Pressure upon the gum causes an escape of a drop of pus along the neck of the tooth; and this may be repeated every five minutes. Day and night, this discharge of pus and infected blood is swallowed with the saliva. The pus comes from a pocket extending from the neck of the tooth, perhaps even as far as the apex of the root. The root of the tooth is often covered by dense black calcareous adherent scales. The pocket is formed by greater or less absorption of the alveolar process surrounding the affected tooth. The pocket may be demonstrated by passing an instrument into it, as is done by the dentist for the pur-

*Read before the Medical Association of Greater New York, New York Academy of Medicine, May 15, 1916.

pose of removing scales and applying suitable antiseptics. In the presence of the scale covered root of the tooth and under the influence of the constant suppuration there is progressive absorption of the alveolar process until the tooth lies loose in a large painful cavity from which it is an act of mercy to extract it. The pocket is much more clearly demonstrated by the x ray as reported in the author's various papers and clinics before dental conventions during the past twelve years. *In many cases the radiograms reveal the cause of the pyorrhœal pocket.* A famous actress was referred to the author for treatment, by the x ray and ultra violet ray, of pyorrhœa affecting the left upper central incisor. Following my usual custom, I made a radiogram of the affected portion of the superior maxilla and found an unerupted supernumerary tooth pressing upon the root of the incisor and acting as a constant source of irritation. This, far from being an isolated case, is but one of numerous cases of pyorrhœa originating from a similar cause. The discovery of this cause affords the key to successful treatment by removal of the unerupted tooth, and saves the patient fruitless attempts at a cure by other means. An unerupted tooth is clearly demonstrated by modern apparatus and technic. In other cases the x ray shows a root filling extruded through the apical foramen or through a false passage and forming an irritant foreign body. Removal of the offending substance either through the root canal by enlarging the foramen, or, more effectively, by an amputation of the apex of the root, cures such a case, and other methods of treatment must necessarily fail. It used to seem desirable to allow a stump to remain after the crown of the tooth had all vanished through decay. This was on the theory that any kind of a root tended to prevent absorption of the alveolar process and so would preserve the contour of the face. Recent cases have shown that this is sometimes dangerous. In one case an alveolar abscess of such a root was the seat of infection producing cardiac and arthritic lesions. In another case infection from such a retained root started up pyorrhœa in a neighboring tooth and neurasthenia.

Pyorrhœa alveolaris makes the teeth very sore and in the first case treated with the x ray the patient, a medical student in London, had to warm his beer and cool his tea. The dental treatment also is exceedingly painful. The suffering and the inevitable loss of the affected teeth and the constant absorption of pus both through the local circulation and also from the discharge that is swallowed, make a cure extremely important.

The treatment of pyorrhœa will naturally be discussed by the dentists. But I may mention that cases which do not yield to ordinary dental measures or to emetine are often referred to me for treatment by the x ray and the ultra violet ray from high frequency vacuum electrodes. These measures as an adjunct to the dentist's treatment have cured at least one case. Very extensive pyorrheal pockets were present about several teeth, and pain and discharge and looseness of the teeth had persisted in spite of dental treatment by Dr. Van Saun. A course of twelve treatments resulted in a cure and at last accounts, three years later, there had been no recurrence. The fact that restoration of the lost alveolar process cannot be expected renders it desirable to cure the disease while there is still enough of the bony socket left to hold the tooth firmly when a healthy condition has been restored.

One of the worst cases of dental infection the author has ever seen was referred for x ray examination by Dr. M. H. Brown. There was a cavity in the lower jaw opening in the mouth behind the last molar tooth. A yard of the foulest gauze packing was drawn out and it seems as if nothing short of cancer could possibly produce such a mass of corruption. The radiogram showed a large thin walled cavity in the lower jaw, at the bottom of which was an unerupted supernumary tooth. The latter lay far from the ordinary tooth bearing area.

Another case, referred by Dr. Fellowes Davis, presented swelling and a fistulous opening. Into this was injected a bismuth paste by means of which the radiogram showed the path of the fistulous tract and its origin in a root at a distance from the swelling.

Several years before the discovery of the x ray, a case was referred to the author, a fistula, which had been discharging externally under the angle of the jaw for seven years in spite of treatment by the best physicians. I was asked to recommend a good skin specialist. It seemed desirable to introduce a probe which led up through the jawbone to the root of a tooth. And it was a simple enough matter under a general anesthetic to extract the tooth and curette the bony socket and the entire length of the fistulous tract. The latter was permanently healed in ten days.

The foregoing is a brief exposition of some of the local lesions directly affecting the teeth which may form the focus of constitutional infections and produce an amazing variety of secondary lesions and symptoms.

The focus of infection not always connected with the teeth. A case in point was one in which an eye and ear specialist had for two years and a half suffered from pain and had constitutional symptoms for which the ethmoid cells had been scraped out and every upper tooth extracted. The pain continuing, spicules of bone had been cut out of the upper jaw by rongeur forceps. A number of radiograms showed no retained root of a tooth as had been suspected and no alveolar abscess. A radiogram of the whole face, however, showed that one antrum was absolutely opaque. It was operated on by Doctor Cryer, of Philadelphia, who removed a mass of pus and granulation tissue, and the abscess was cured. If the x ray had been resorted to in the beginning, two and a half years of suffering and the useless extraction of all the upper teeth would have been avoided.

The x ray will reveal any source of infection connected with the teeth or the pneumatic sinuses of the face, if these are present. If these were undiscovered and untreated there might follow the most serious consequences, which could easily have been averted. A case in point is described later, in which the author discovered the cause, but the teeth seemed perfectly sound to the dentist with the usual means of examination. The patient, himself a physician, had terrible neuritis and high blood pressure, and eventually died of apoplexy, apparently from neglect to remove the cause in time.

CONDITIONS FROM WHICH ALVEOLAR ABSCESS AND PYORRHŒA ALVEOLARIS MUST BE DIFFERENTIATED.

Pulp stones. These are calcareous concretions in the pulp or "nerve" of the tooth. They cause pain, and the patient comes for a radiogram which is expected to show the site of an alveolar abscess. The picture, however, shows an area of density in what should be the perfectly transparent contents of the pulp chamber. The "nerve" is more or less irritated, and there is in the figure a slight departure from the normal appearance of the bone surrounding the apex of the root. Such cases are treated by removal of the "nerve."

Pain similar to that of chronic abscess and very slight radiographic indications of apical irritation may occasionally be simply the result of constantly repeated pressure: this tooth alone making contact with the opposite teeth when biting or chewing. The dentist can remedy the cause by regulating the teeth slightly or by grinding the surface of this tooth or the one it collides with. This explanation of the case should, however, be accepted with more than the traditional grain of salt. If the pain ceases and the radiographic appearance becomes normal, that is all that can be desired. But if more or less discomfort remains and the radiographic appearance continues distinctly abnormal, the case should not be temporized with, even though the usual tests by the dentist indicate a vital and healthy tooth. The symptoms and radiographic appearance in such a case at the start were as described above. Grinding the surface of the opposing teeth did away with their collision, but the discomfort and abnormal radiographic appearance persisted for years. Then there was an attack of intense pain necessitating the use of morphine and accompanied by swelling and suppuration. This required months of treatment through the root canal. A year later the root was filled to the apex and surrounded by healthy bone.

The treatment of just such a case should, according to the author's views, consist in drilling into the tooth and removing the dead or chronically irritated nerve. This should be done before putrid decomposition has poisoned the alveolar or bony socket almost beyond recovery. The very serious subsequent developments in this patient are described on another page.

Cysts. A cyst in either the upper or the lower jaw may cause symptoms resembling those of alveolar abscess, and the radiographer should be careful to differentiate between the two. In a recent case treated by Doctor Clawson there was a large area of transparency between the roots of the lateral incisor and the canine. Both these teeth had healthy "nerves." The cyst contained a clear straw colored liquid and was successfully treated by incision, curettage, and packing, without disturbing the two neighboring teeth. A large, thin walled, clearly defined cavity without local symptoms is frequently a cyst; while an alveolar abscess is often evidenced by decalcification, gradually shading off into healthy bone without a distinct line of demarcation.

A dentigerous cyst commonly shows as a hard swelling upon the jaw and is essentially a cavity in the bone wherein lies an unerupted and usually supernumary tooth. Exceptionally the x ray shows that such a swelling is an *odontoma*, a tumor of almost stony hardness and consisting of a conglomeration of nodules of dentine covered by enamel.

Alveolar abscess and unerupted tooth combined: In a patient seventy years old with painful swelling of the lower jaw, the dentist could not determine whether the cause was an unerupted tooth or an alveolar abscess. The radiogram showed that both conditions were present. Another patient, aged fifty years, was referred for an examination to determine the presence of an unerupted upper canine. The radiogram showed the unerupted tooth and an unsuspected alveolar abscess of an upper molar.

An impacted wisdom tooth, lying perhaps in a horizontal position concealed in the jaw and growing directly against the root of the second molar, causes pain suggestive of neuralgia or neuritis. It is mentioned in this place because of the misinterpretation that has sometimes been made of the radiographic appearance. The unerupted tooth lies in a natural cavity of the jaw, and if the root is not fully developed a transparent area is seen at that end. This represents soft tissue in which tooth substance is developing and is not an abscess. The flaring foramen of a growing tooth in a young person should not be mistaken for an abscess.

LESIONS AND SYMPTOMS SECONDARY TO INFECTION CONNECTED WITH THE TEETH OR THE PNEUMATIC SINUSES OF THE FACE.

Tuberculosis. It has long been known that one of the common sites of infection in pulmonary, bony, and glandular tuberculosis, is an alveolar abscess. The continued existence of such a pus pocket is therefore a distinct menace to life itself.

Neurasthenia. A man of powerful physique, weighing 220 pounds, was lately referred to me suffering from neurasthenia. He complained chiefly of not being able to stand as much business activity and responsibility as one of his apparent strength would be expected to. There had been no dental, but some nasal symptoms. The radiograms showed pyorrheal pockets, including one of the right lower second bicuspid, due to irritation from the retained and infected roots of the first molar. An anteroposterior radiogram of the head showed the frontal sinus to be solid, either from pus or some other opaque substance or because of congenital absence of the frontal sinus. In another patient with neurasthenia applying to the author for x ray examination, the radiogram showed an alveolar abscess with erosion of a considerable part of the root. The canal was only partly filled and the foramen wide open.

Chorea. One of the most conservative neurologists has just made the statement that eighty per cent. of the cases are due to streptococcic infection. He says that the prognosis is entirely changed by this discovery.

Arthritis has become known within the last few years to be frequently due to toxemia originating and maintained by an alveolar abscess or pyorrheal pockets. Since this discovery, many a case of acute or chronic "rheumatism" has been cured in a short time by treating the focus of infection.

CASE I. *Arthritis, pleurisy, endocarditis, and meningitis.* A patient has been already referred to who had a trouble-

some lower first bicuspid which the dentist at first thought was simply irritated by striking against an upper tooth. This went on to the formation of an alveolar abscess. Following prolonged treatment through the root canal the tooth was filled. The x ray showed this tooth in an apparently cured condition. The root filling reached about to the apical foramen and the surrounding bone had regenerated. During the latter part of the summer, the patient began to complain of renewed discomfort and wanted to have the tooth extracted, but a radiogram showed it to be all right. Nevertheless a series of fugitive attacks of arthritis, myositis, and neuritis occurred. Each attack lasted a week or ten days and produced severe pain. During these two months the patient lost twenty pounds in weight and at times had a slight rise in temperature. A diet from which sugar and meat were excluded, and medication by aspirin, salophen, and sodium salicylate produced little or no effect. Finally a few applications of high frequency currents from ultraviolet vacuum electrodes seemed to have brought these attacks to an end. On December 5th, however, she was seized by sudden severe pain in the left upper quadrant of the abdomen, with great rigidity of the left rectus muscle. This pain was not relieved by laxatives and enemata and gradually extended to the left side of the chest, where in two or three days the physical signs of pleurisy with effusion developed. The heart was greatly dilated and there were rasping mitral murmurs. Absolute rest in bed, a purin free diet, and an ice bag over the heart, temporarily reduced the severity of the symptoms without much change in the physical signs.

After five weeks of this acute illness, Dr. Harlow Brooks, in consultation, found that she presented the clinical picture of tuberculous peritonitis and tuberculous pleurisy on the left side. There was also flatness at the base of the right lung, which with the onset of meningitic symptoms and constant leucocytosis led to a suspicion of abscess which was disproved by an exploratory puncture. The meningeal symptoms became rapidly worse, the patient was unable to speak a connected sentence. There were several severe convulsions, lasting from an hour to an hour and a half each. A spinal puncture showed a clear fluid under normal pressure and containing no microorganisms, and negative to the Wassermann test. The spinal fluid contained one lymphocyte to about fifteen red cells. The blood contained no microorganisms and was negative to the Widal and Wassermann tests and contained 25,000 leucocytes per cm. The urine contained albumin and casts. A radiogram of the chest, made at the bedside with a portable outfit, showed no collection of fluid in either side of the chest, but some mottling on the right side. It showed a greatly dilated heart and an enlarged thymus gland. The pulse was 120, respiration 34, temperature 102.5° F.

Dr. N. B. Potter and his assistant, Doctor Ordway, had always been suspicious of streptococcus infection, possibly from the teeth shown in my radiographs. And it had been the plan that the first time the patient went out of doors it should be to the dentist's office to have the suspected second bicuspid drilled into and the question of the life or death of its nerve decided. It had now become evident that it was a question of the life or death of the patient to discover and remove the source of infection at once, unless it should prove to be tuberculous and not removable. Dr. Henry Sage Dunning accordingly operated upon the patient in bed under local anesthesia. He extracted the originally infected first bicuspid without difficulty. The hooked root of the second bicuspid broke off, as had been feared, and had to be chiselled out. The operation took about two hours, but was entirely painless.

Improvement in every particular began from that moment. The original tooth was found to be sterile, but a culture of Streptococcus viridans was obtained from the second bicuspid, and on the fifth day after the operation inoculations with autogenous vaccine were begun. After this the improvement was more rapid, and on the thirteenth day after the removal of the teeth the respiration was 24, pulse 74, temperature 98° F.; the patient's strength increasing daily. The physical signs were clearing up. Pneumonia and hemiplegia were later developments, but there was still a prospect of recovery.

Neuritis, neuralgia, tic douloureux, sciatica, constitute a group of cases in which our first thought is to determine the presence or absence of a cause connected with the teeth or sinuses, for no ordinary medical agents will avail if the trouble is due to such a cause. A patient had very severe tic douloureux spasms of pain at a few seconds' interval, feeling exactly as if a tack were driven into the jaw bone. The x ray and high frequency currents from ultraviolet ray vacuum electrodes gave great relief, but the final cure was accomplished through overcoming intestinal autointoxication, which appears to have been the underlying cause. The negative x ray findings saved the patient from needless and ineffective sacrifice of his teeth. A patient of the late William T. Bull had been treated by neurologists and electrologists, in this country and Paris, for trigeminal neuralgia which had persisted for three years. Doctor Bull had arranged to perform an operation for the removal of the Gasserian ganglion, but as a final preparatory step sent her for an x ray examination. The picture showed an unerupted tooth near the angle of the jaw, which Doctor Bull operated upon, with a cure of the disease; the patient was also saved the fruitless suffering and danger of an intracranial operation.

Paroxysmal cough. Such a case in a man who has recently become blind was referred to the author by Doctor Osborn. The radiograph showed alveolar abscess and numerous pyorrheal pockets.

Case II. *Arterial hypertension,* leading to arteriosclerosis with many distressing symptoms and a prospect of apoplexy and death, calls for an x ray examination of the teeth and pneumatic sinuses. A patient with extensive pyorrheal and abscess areas about the teeth, was professor of laryngology and rhinology in one of our universities, and had been referred to me for treatment of neuritis of the arm. He was under treatment elsewhere for high blood pressure, which I thought was of the same toxic origin as the neuritis. Suspecting dental infection, I made radiographs which showed the area of infection. I most strongly urged treatment, either by extracting the affected teeth or by applications made through the root canals. The dentist, however, found the teeth healthy according to his tests, and refused credence to the x ray findings. It was before the general recognition of this source of systemic infection, and the doctor was allowed to go from bad to worse until he was in a desperate condition in the Battle Creek Sanitarium. There he met a dentist who believed the story told by the radiographs. A number of terribly abscessed teeth were extracted, with immediate and marked constitutional benefit, but on his return to New York the radiograph showed other infected areas in the upper jaw from which all the teeth had been extracted, and in a few weeks he died of apoplexy. Timely extraction of all the infected teeth I believe would have saved this useful life. He was only fifty-six years old.

Cardiac lesions secondary to dental infection with its accompanying rheumatism, nephritis, or neuritis, occurred in twenty-three out of thirty-one cases of Hartzell, Henrici, and Leonard, and were evidenced by valvular disease, usually mitral insufficiency. Four cases had a diagnosis of myocarditis and three of pericarditis. Removal of the causative foci of infection prevented further damage to the heart in valvular cases, and general medical measures were adopted to favor compensation.

Case III. *A cardiac lesion,* which was the most important result of dental infection. The patient had a mitral murmur, mitral regurgitation with some compensatory enlargement of the heart, but no edema of the extremities or dyspnea. Getting up quickly from a reclining posture would cause him to drop back, practically in a faint, and he had to avoid turning suddenly for the same reason. The urine contained numerous

granular casts, calcium oxalate, uric acid, and contained albumin. The recent occurrence of a swelling of one or two finger joints caused him to have radiographs made of all the teeth. Pyorrheal pockets were found about several teeth; and there were three alveolar abscesses with considerable destruction of bone. The three abscessed teeth were extracted. The first two contained no pathogenic microorganisms. The third yielded a culture of Streptococcus viridans from which an autogenous vaccine was prepared.

Exophthalmic goitre. This is a disease in which an x ray examination of the teeth is indicated. Arising at an early stage, as it often does, it might seem unlikely that dental infection should have been an exciting cause. In nearly every family some case of dental abscess with local symptoms may be found to have occurred during youth or childhood. Those with manifest symptoms have usually been treated more or less successfully, but the x ray alone would have disclosed those with an insidious course. In one case there had been alveolar abscesses of two lower molars for a long time. In the other case all the upper and lower teeth, except two or three isolated ones, had been lost through pyorrhea.

Eye diseases. Some cases which were formerly diagnosed as rheumatism or syphilis have been found to be due to dental infection. The uveal tract, including the choroid, the ciliary body, and the iris, is most apt to be affected by this cause. Cases have been known in which even one eye has been lost and this cause of infection discovered in time to save the other. One patient with endocarditis and hemiplegia from alveolar abscess had neuroretinitis as an effect of meningitis, and at another stage episcleritis as a direct effect of the infection or as a reaction from the autogenous vaccine. Another patient became blind and was without perception of light before the infection was discovered, but perhaps not in consequence of it.

Tinnitus aurium was the symptom complained of by the patient referred to me by Doctor Clawson. The radiograms showed no dental lesion. The ringing in the ears may in other cases be an indirect result of high blood pressure directly caused by dental infection.

Spinal cord lesions have recently been recognized to be sometimes due to infection arising from the teeth. A patient of Doctor Solley's, with pernicious anemia and numbness and loss of power in the upper and lower extremities, was in a desperate condition with thirty-five per cent. of hemoglobin and becoming weaker every day. Dr. Pearce Bailey found positive evidence of general, not merely lateral spinal sclerosis, with symptoms indicating a stage of irritation rather than destruction of the nerve fibres and cells, and with a possibility of partial or complete cure if the source of infection was discovered and removed. The radiograms showed alveolar abscesses of several teeth. The teeth were extracted and an autogenous vaccine prepared from the pus was administered. There was immediate improvement in her general condition and restoration of power in the arms, and there is hope of a complete recovery.

Gastric ulcer. The most surprising success has been reported by Hartzell, Henrici, and Leonard[1] in the treatment of gastric and duodenal ulcer. Unmistakable cases were cured so promptly as to indicate a causative relation between the dental infection and the destructive process in the gastric wall. We cannot tell which of the two factors is most destructive. There is the irritation from the infected matter which is constantly swallowed with the saliva and there is the hematogenous infection. The demonstration of this easily discoverable and removable cause of many cases of gastric and duodenal ulcer is a fact of great importance. Consider the number of these cases coming to the röntgenologist for diagnosis after months or years of pain and loss of weight and strength; also the tendency to recurrence after medical treatment, the tendency to produce adhesions interfering with gastric and intestinal digestion and transit, the danger of adhesions following operative treatment, and the ever present menace of a chronic ulcer developing into cancer.

Alveolar abscesses of both roots of a lower molar tooth were one of the lesions in the case of a lady, who for two years had been treated unsuccessfully for symptoms of gastric or duodenal ulcer. After seeing the radiograph, she recalled that three years previously there had been pain about this tooth, the only treatment having been by counterirritant applications. Alveolar abscess was one of the dental foci of infection in a lady who had a large hemorrhage from the stomach, with temporary recovery under absolute rest and suitable diet. Later there were further gastric symptoms, and a large six hour residue as demonstrated by a radiograph. The dentist thought it wise to extract this tooth and two others.

It seems as if x ray examination of the stomach and of the teeth should go hand in hand in cases of suspected gastric or duodenal ulcer. Of course radiographs of the stomach and intestine should be made to exclude the presence of a lesion requiring an abdominal operation.

Cholecystitis and gallstones. Charles H. Mayo, from experience based upon 6,000 operations for these diseases, draws the conclusion that they are due to infection. Septic inflammation of the gallbladder and hepatic duct leads to adhesions followed by stagnation and concentration of the contents of these hollow viscera. He believes that the primary source of infection is most frequently a focus in the mouth. He says that the old statement that many persons have innocent gallstones has been disproved. All gallstones are a source of illness and danger. These observations are confirmed by other abdominal surgeons.

The moral to be drawn is that early x ray examination of the teeth in every case of pain in the upper part of the abdomen will frequently reveal foci of infection, and attention to these may often prevent cholecystitis, adhesions, and gallstones.

Cancer of the stomach and bile duct. Malignant disease of these organs seems to start from inflammation, ulcer, and adhesions. Discovery and remedy of the primary cause at the earliest possible moment will doubtless have a powerful prophylactic influence.

CONCLUSIONS.

A putrescent mass in the pulp chamber of a tooth may exist for months or years because the walls of the cavity cannot collapse and are incapable of

[1] Report of the Minnesota Division of the Scientific Foundation and Research Committee, *Journal of National Dental Assoc.*, November, 1915.

throwing out granulations and eventually filling the cavity with healthy tissue, like the natural process of cure in an abscess in the soft tissues of the body. This putrescent mass may constantly poison the bony tissues surrounding the apical foramen sufficiently to produce an effect clearly recognizable in a radiogram. This condition may be unknown to the patient, and sometimes may not reveal itself to the usual tests applied by the dentist. From this long persisting source of infection, secondary lesions and symptoms of the gravest and most diversified character may arise.

The x ray is to be depended upon to show whether or not the source of trouble is connected with the teeth or the pneumatic sinuses, and if so, whether the trouble is due to malposition and unnatural pressure or to infection. It would be a mistake to regard every case as due to the teeth and proceed to sacrifice the latter without first making a radiogram which may acquit them of any complicity in the matter.

850 Seventh Avenue.

ECZEMA IN CHILDREN.*

By George W. Crary, M. D.,
New York.

Eczema must still be described as comprising forms of dermatitis which as yet have not been assigned to any other distinctly specific entity; only when a dermatitis cannot be classified as belonging to any other group of diseases of the skin may a diagnosis of eczema be made. Only when an existing erythema is determined not to be a simple intoxication erythema, nor one of the acute infectious diseases, not an urticaria nor due to mechanical, thermic, or chemical irritation, nor to belong to any of the other forms of erythema, may a diagnosis of an erythematous eczema be made. Similarly, a vesicular eruption must be determined not to be a zoster or other form of herpes, including dermatitis herpetiformis, the early stage of an impetigo contagiosa, dysidrosis, dermatitis calorica, or any of the other forms of dermatis accompanied by the formation of vesicles or bullæ, before a diagnosis of vesicular eczema may be made, and this same method of diagnosis by exclusion must be pursued throughout in the other forms under which eczema may present itself.

With such a conception of eczema before us, it follows that the etiology of the disease will often be obscure and nearly always varied, and mixed. Such a mixture of causes will most often be found to be internal and external, and the relative potency of the two will vary much in different cases, and in a given case the one may so predominate as to cause us to diagnose the condition as an eczema of external origin, or as an eczema of internal origin, and from the point of clinical therapeutics this is perhaps the important point to establish. In children two years of age, or less, an eczema of extensive distribution, of purely external origin, is rare, though in perhaps nearly all, if not indeed in all, the external cause is present as the determining cause; the predisposition to the outbreak being established by causes of internal origin. The external cause is quite certainly of a bacterial nature, but the specificity of the particular microorganism has not been established, though affirmative statements have been made by a few investigators. If there is an absence of proof by the bacteriologist of the responsibility of any one germ, it is not an unwarranted assumption upon the part of the clinician to assume the activity of more than one form of microorganism. In young children, the site of the internal causation for an eczema is the gastrointestinal tract, and is of the nature of an autointoxication due to feeding which in that particular subject, at that particular time, is faulty in that, for the time, the subject is unable perfectly to digest or to assimilate the food taken, or because there has been developed in the child a hypersusceptibility to certain foodstuffs. Such liability to food anaphylaxis as a cause of outbreaks upon the skin has very recently received much attention. Strichler and Goldberg (1) and McBride and Schorer (2) have given us valuable accounts of their experiments upon the skin reactions to food anaphylaxis, and White (3) reports his study of the effect of this form of anaphylaxis upon the occurrence of eczema in infants. The power of certain foods specifically to cause the outbreak of certain forms of dermatoses or even of certain varieties of eczema, must be considered "not proven." But before the phenomena grouped under anaphylaxis were named or understood, and long before intoxication by foods was included under the heading, it was known that certain subjects, especially infants, would at times manifest a susceptibility to the ingestion of certain foods, and these often of the simplest. Babies have been thrown into convulsions, with even a fatal outcome, by even small amounts of egg albumin, taken by stomach or injected under the skin, and milk has been known to cause similar disturbance. Nearly all authorities, however, admit that there are eczemas in infants which are quite independent of any form of food ingestion, and an intestinal autointoxication may result, as McBride and Schorer have pointed out, from an indifferent food which has undergone change, either within or without the body of the host, through the action of parasites. We have cases also arising from so called reflex causes, and one of the most frequent is that associated with an adherent prepuce, especially in female infants. Undoubtedly dentition may also act as an exciting or predisposing cause of a reflex eczema.

TREATMENT.

Upon approaching the treatment and cure of eczema, we are met, first, with a prevailing belief among the laity, and entertained indeed by many of the profession, that the cure, or at least the rapid cure, of an eczema is fraught with danger to the life of the child. In his report of his fatal cases of eczema, Purcell S. Hichens (4) lends his support to this belief by concluding to give to mothers of eczematous infants the warning that their children may be better off with eczema than without, and that its cure is not an unmixed blessing. In five

*Read at a meeting of the Medical Association of the Greater City of New York, April 17, 1916.

of these six cases, details of the disease and its treatment are given, and it is of some interest to note that in four, lead, in the form of Goulard's extract or of ointment or emplastrum, was used in the external treatment. In the discussion of the report, Doctor Guthrie suggested that death might sometimes be due to the poisonous nature of external applications, and the extensive application of remedies to the delicate skin of a child which might, if absorbed, prove harmful to the general health or even to the life of the infant, should be most carefully guarded against. An examination of this report would further suggest that it was not the rapid cure of the eczema that had proved fatal, for in none of them was a quick cure obtained. In two cases improvement was noted in two weeks and in thirteen days, respectively, and in one other case a cure was established in four weeks. It would seem more likely that these deaths took place as a result of the intestinal autointoxication, of which the skin manifestation was only one symptom, and not perhaps a very important one, as in two of the cases the eczema was limited to the head and face, in one other the nates were involved, and in still another one arm was the site of the eczematous process. In one of Guthrie's cases which came to autopsy, he found marked congestion of the whole gastrointestinal tract, with raised, swollen, and red Peyer's patches. Whenever this suggestion of the danger of a quick cure has been made to me by an anxious mother, I have been more accustomed to reassure them by remarking upon the unlikelihood of a quick cure than to warn them of the dangers of such a cure. The cause of eczema in infants, the cause of the illness of which the eczema is a symptom in infants, being so intimately connected with faulty feeding, it seems to be the duty of the pediatrist to assume direct control of the case, and for the dermatologist to assume the position of consultant. Certain general guides may, however, be indicated. Freeman (5) advises that the food be cut down to the caloric requirement, that the ration be balanced, and that digestion be aided. He advocates the introduction of malt soup into the dietary to maintain the proper caloric balance, and he prohibits stewed fruits and cream. Southworth (6) also finds malt soups to be a valuable aid in the nutrition of infants who do not properly digest and assimilate other forms of modified or unmodified milk feeding. Ochs (7) likewise believes in cutting down the amount of food and the number of feedings. Varnot (8) in nursing infants recommends a change of milk, believing this to be less dangerous than the external treatment. I am accustomed to forbid eggs and sugars in the diet of the older babies, a position founded largely upon clinical experience. In the choice of external dressings, protection is first of all to be sought, but the dressing itself should be capable of absorbing moisture from the skin, and should not be impervious to it. For this reason pastes rather than ointments should be the base, and such a paste is better than a lotion when a large surface is to be covered, as under such circumstances the application of lotions as wet dressings is sure to be depressing to the vitality of the little patient. Again I have so often found that the application of any fat to the skin of an eczematous infant proves irritating, that I now invariably use an Iceland moss jelly, either to dilute the petrolatum base, or alone as the base for whatever medicament I wish to apply. I believe in the introduction of a mild antiseptic into the external treatment, and I generally employ a resorcin, as euresol, the monoacetate according to the manufacturers of the preparation I use. This I introduce into the paste in the proportion of one, two, or even three per cent. With this may be combined small percentages of ichthyol, up to five or ten per cent. Where a purely protective dressing is required, the preliminary application of the Iceland moss jelly, followed by thorough dusting on of an indifferent powder, composed usually of zinc oxide and powdered talcum, and allowed to dry, has oftenest proved of value. Where such an application is made, the flexures, as in the cubital triangles and popliteal regions, must be softened when dry by the application of petrolatum, to prevent cracking or a milder irritation of the skin upon movements of the extremities.

535 PARK AVENUE.

INFECTIONS OF THE BONES AND JOINTS.*

BY PERCY W. ROBERTS, M. D.,
New York.

It has seemed to me that it might be of more interest to give some impressions gathered from every day work in the orthopedic clinics on joint involvements, than to prepare a studied paper, as I assumed that the symposium would cover the general phases of the subject. Arthritis, however, is of very great importance. The orthopedic clinics are crowded with cases of joint lesions in all stages. We see them in the early and late stages. It would seem that there were two general types of the condition, the subacute, and what simulates a metabolic form such as we see in senility. The question arises, What may be the origin of these cases? Personally, I believe it is at one time or another an infection, despite the observations to the contrary. Undoubtedly, subacute forms result from infections, and unquestionably the teeth and tonsils are prominent portals of entry for the bacteria.

I am somewhat of a conservative, however, in regard to the dental and oral infections generally. That does not mean any lack of enthusiasm for the work that is under way at present and which has taken such a strong hold on us, but I am conservative because of my experience. Undoubtedly, the teeth are often the cause of chronic multiple arthritis, but when we see patients who have had all their teeth removed and their tonsils taken out, and still the arthritis goes on, is it fair to assume that the cause lies in the teeth or tonsils? There are various

*Read before the Medical Association of the Greater City of New York, May 15, 1916.

sources of infection, and we are too apt to regard those most accessible as being the most probable. Very often the accessible parts, although they contain cocci, are not the source of the offending organism—for joint troubles, as is well known, are not due to any one type of organism, or any one strain. They follow infections of any sort—staphylococcus, streptococcus, gonococcus, scarlet fever, grippe, typhoid, etc., and it is seldom that the organisms themselves are recovered from the joints.

That means that it is some irritant or toxin which disturbs the joint, and it is not always possible to determine whence that toxin arises. The throat is probably even more important than the teeth as a matter of consideration in determining the cause of joint infections, for numerous organisms find lodgment there and autogenous vaccines frequently give most brilliant results—although quite as frequently they fail.

To diverge for a moment or so from the dental and oral infections to say a word or two about treatment, because many of the cases which come to us have been the rounds of the hospitals and clinics, springs, and baths, and have spent time and money without results—one of the most common errors in the treatment of multiple arthritis is the assumption that joints should be kept in motion or they will be sure to have ankylosis. There is nothing more fallacious. If I had to choose one form of treatment for acute or subacute arthritis, it would be absolute rest. We frequently see joints which are enlarged, tender, and extremely painful on motion that need immobilization, and yet when plaster of Paris is suggested as the treatment—this applies particularly to the knee—not only the patient, but very often the physician hesitates and says No; and it is only by considerable urging that such treatment is permitted. As a matter of fact, nothing is better. Joints which are enlarged and tender and have been painful for months, or perhaps years, often improve remarkably after three or four weeks in plaster of Paris. It is very seldom that a knee joint of the subacute type will not come back nearly to normal—provided, of course, that there have not been extensive bone or cartilage changes. Therefore, I say, that if I had to choose one form of treatment it would be immobilization.

The best illustration of the innocuous nature of immobilization in plaster of Paris is seen in cases of hip disease in which the knee is kept at rest for two, three, four, or five years, and yet ankylosis never follows. The knee joint is stiff when first released from its splint or brace, but restoration of function always occurs.

Inasmuch as the matter of dental and oral infection has been pretty well covered, may I say another word about chronic joint cases—that is, the early diagnosis? It is a little difficult to make a correct diagnosis in the early stages; in the later stages, it is very simple, but when a patient comes in with a stiff finger or a painful knee we cannot always be sure whether it is a local or a progressive condition. In going over a very large number of these cases, one point that has been of some service in determining the nature of the trouble has been the tenderness of the bones at the point of insertion of the long muscles—such as the tuberosities of the condyles of the femur and the humerus, the great trochanter, and the head of the fibula. These are nearly always tender in osteoarthritis, and yet the patient is quite unaware of that fact until pressure is made upon them. In following up cases of this kind, which in after years have gone on to a chronic multiple arthritis, I feel convinced that this finding is of some value in arriving at an early diagnosis. I have seldom seen it in other diseases, syphilis excepted. It is not, I think, present in acute infections of the joints.

I believe that the teeth should be x rayed in every chronic joint condition. I have so often seen relief from the proper treatment of the dental lesions that it seems very wrong in the light of our present knowledge to let a patient go on suffering without attention to the teeth. Again let it be said, however, the teeth are not always wholly responsible. Very often in chronic cases, where there is exacerbation, a pus pocket at the root of the teeth will be found to be the cause of that exacerbation, and relief of that will relieve the symptoms. I believe, therefore, that radiography of the teeth is one of the fundamental principles in the treatment of chronic arthritis.

576 Fifth Avenue.

DIATHERMIA.*

Its Technic and Its Indications,

By Heinrich Wolf, M. D.,
New York.
Chief of Department, Physical Therapy, Mount Sinai Hospital and Dispensary.

Diathermia consists in the induction of a higher temperature in the body, in an area between two electrodes, by the electric current. The importance of increasing the temperature of the tissue in a given area has been recognized for many years. we may say, for centuries. Up to 1907 we had no reliable method of doing so. It is true that Bier, through his splendid work on hyperemia, has helped greatly to popularize the use of heat, but we were obliged to restrict ourselves to the employment of conductive or radiant heat. Whether we use electrically heated radiators or gas apparatus, fango mud, hot water bag, or other agents, the object is always to produce a higher temperature in the body.

Diathermia is based on an entirely new principle. We know that electricity produces heat by passing through a conductor in proportion to the resistance offered, still the use of the galvanic, faradic, or static current was not possible on account of their strong chemical and stimulating action. Long before the current was strong enough to produce appreciable heat, either the chemical action of the current would have destroyed the tissue, or the stimulation would have become unbearable.

The problem was solved when Tesla discovered that it was possible to pass electrical currents of great strength through the body, without causing reaction, provided that the current changed direction

*Read before the meeting of the Medical Association of the Greater City of New York, June 5, 1916.

very frequently; that is, if we employed a high frequency current. The French school had long before realized the possibility of producing heat by the high frequency current, but considered it rather a disadvantage, and it was left to Zeynik and Bernat, in Vienna, in 1906, and independently to Nagelschmidt, in Berlin, to realize the importance of this fact.

As far as the theory of diathermia is concerned, it can be explained in a few words. Every electric current, direct or alternating, passing through a conductor produces heat. The high frequency current is an alternating one caused by the discharge of a condenser in the secondary coil. The duration of this spark is only about 1/50,000 of a second. Now suppose we have 500 such sparks in the second, it is evident that the current is passing during only 1/100 part of the time unit, while ninety-nine parts are without current. The problem was to increase the number of discharges to such an extent that the amount of current passing through the body would be considerably greater. This has been accomplished in more than one apparatus. It is quite impossible to enter deeper into the description of the theory of this method, and I have to refer my readers to the textbooks which deal with the treatment.

Up to a short time ago, the ordinary high frequency apparatus was used exclusively in this country with the ordinary or the multiple spark gap. The trouble with such apparatus was that the currents produced by them had a very high tension, the electrodes sparked, when strong currents were used, and the amperage was correspondingly small. Since then an apparatus has been manufactured, according to my suggestions, combining simplicity with efficiency. The older apparatus, which I have been using a number of years, has the disadvantage of being too complicated, and only men well acquainted with electrical technic can use it without trouble.

I wish to discuss the theory of the action of diathermia. All that we positively know is that it increases the temperature of the tissues between the two electrodes. We have no proof whatever that electric energy in itself has a curative effect, but we can safely say that the effect of diathermia is identical with that of local heat.

Physiology tells us that heat relaxes the tonus of the tissues, and by the relaxation of the muscular fibres of the blood and lymph vessels it dilates them. The arteries of the neighboring parts not being affected, the blood rushes in the direction of least resistance, and hyperemia in the treated part results.

The question can be asked as to the difference between hyperemia produced by hot applications of any kind, and diathermia. It is this: By hot applications we increase the temperature of the skin and the underlying tissue; experiments having shown that heat so applied does not penetrate to any degree, although we know that a strong hyperemia of the skin results. A change in the local blood supply of such a degree as produced by hot applications, cannot exist without a corresponding dilatation of the afferent vessels. We can assume that these become dilated by reflex action.

The difference between these two forms of treatment lies in the fact that we can increase the local blood supply better by means of diathermia than by external heat application, as it increases the temperature of the tissue itself, causing dilatation by direct influence and not by reflex. We know much less about the influence of heat on the local metabolism. It is true that an increased temperature quickens the chemical processes, but to what extent, and in what direction, we are not able to say, as it is not permissible to draw conclusions from hyperpyrexia in infectious diseases. We can safely say that diathermia acts by causing an increase of the blood supply in the area treated, thus aiding nature in the cure; it also softens the tissue, making it susceptible to other mechanical treatments, like massage or gymnastics. It probably increases metabolism; chemical processes being enhanced by increase of the temperature. The fact that diathermia is dangerous in acute infectious conditions, might indicate that, and in spite of its bad effect on microorganisms, it should not be used where the local metabolism is abnormally increased.

A great deal has been expected from the influence of increased heat on bacteria. We know that the increased body temperature in infectious diseases is to some extent a curative action, but opinions are divided as to the value of increasing the temperature in an infected area. When diathermia was first tried, it was hailed as an ideal method in the treatment of acute gonorrhea, as it was known that the gonococcus was harmfully affected by an increase of the temperature. I shall discuss this point later, when speaking of the contraindications to diathermia.

INDICATIONS.

The indications for the treatment with diathermia are numerous. I have had very good results in the treatment of intermittent claudication, a condition due to occlusion of the arteries. There are two forms of this disease, the senile gangrene and thromboangitis obliterans. While in the former diathermia gives very good results in most cases, the latter is much harder to treat. In the senile gangrene we know of only one contraindication to diathermia, and that is thrombosis of the veins. This is quite plain. If we dilate the arteries increasing the blood supply without allowing the venous blood to flow on, we must face a venous stasis; the circulation will become stagnated and the result will be disastrous. In thromboangiitis obliterans, we have to deal most likely with an infectious condition, which is frequently associated with phlebitis migrans. I noticed that the patients with phlebitis always became worse if the treatment was repeated two or three times a week, and I decided not to treat these cases any more with diathermia, except when the disease was confined to the arteries. I have a number of cases on my records which have improved under this treatment, but we must be careful not to expect too much. A number of these cases do not progress quickly; some of them terminate favorably without treatment, and only after a long period of time can a definite conclusion be reached.

In cases of increased blood pressure, diathermia has given excellent results. I do not wish to enter into the discussion whether lowering of the blood pressure is desirable. We can accomplish it in the

prearteriosclerotic stage in cases where the etiology is unknown. I do not consider it indicated in patients with kidney disease, nor in cases where marked arteriosclerosis has developed, neither do I hold that we should be satisfied with the result accomplished.

It is necessary to regulate the diet so as to eliminate the etiological factor; but I say that it would be wrong to expose a patient to the danger of a hemiplegia only for the sake of principle, instead of lowering it to a reasonable degree. The results are fairly permanent; at least I treated some patients years ago, and the blood pressure stayed low (relatively) for many months. I never try to lower the pressure below 160 mm. On two occasions I noticed weak spells during the treatment. Examination showed that the blood pressure had gone down considerably. Treatment was stopped, and the strength of the current as well as the duration were diminished. I very rarely go higher than 900 milliamperes and twenty-five minutes at each treatment.

I know that in using the ordinary high frequency machine we consume considerably more current, but it seems that with the diathermia machine no higher temperature can be tolerated, and the results are better.

In the treatment of trifacial neuralgia and tic douloureux the results are very good, but not all forms react equally well. Cases which had been operated in or injected are often refractory, and so are those where pain is continuous, but patients who have the real form of tic, and the neuralgia in old people which is evidently due to arteriosclerotic changes in the vasa nervorum, respond splendidly to diathermia. It is difficult to describe the technic in detail, and I only wish to bring out the fact that the diseased nerve must be placed between the two electrodes. I have to refer my readers to my publication on this subject.

The results of this treatment in pain after fracture as well as in chronic myositis (lumbago), in tenosinovitis, and in trigger finger are surprising. In the short space at my disposal it is impossible to describe the technic in every case, but it is necessary to state that the most important point is to make a correct local diagnosis. We cannot expect results if we apply the current in the wrong place. This holds true in every method of physical therapy. Let me give an instance. In a case of lumbago, the whole muscle is very seldom involved. It is necessary to determine where the pathological process exists and to treat that spot in order to obtain the desired result. I believe that the poor results obtained by some physicians and laymen are due solely to improper diagnosis.

Lately, much has been said about sacroiliac disease. I have seen a number of these cases, and must say that there is no treatment, except fixation, which will give such good results as diathermia.

Little is known of the great value of diathermia in the treatment of certain heart diseases. I have used it in stenosis of the aorta. The pulse was typically small, the pulse wave long, the systolic pressure ninety mm. Hg. Immediately after the treatment the pulse became much better, and the blood pressure rose to 110 mm. Hg.

Naturally the electrodes had to be placed so that the aortal valves were lying between them. In another case there was a distinct change in the region of the coronary arteries as shown by the x rays. The patient was suffering with real stenocardiac attacks. During the treatment the improvement of these subjective symptoms began, and the patient lost her pain completely for hours. The pain returned at times the next day, but I was informed that there was considerable improvement, though naturally not permanent.

A few words about the contraindications to diathermia: Of these, I know two very important ones; the acute and subacute infections, and venous thrombosis. When diathermia was first tried, physicians expected a great deal. It was known that the gonococcus was very sensitive to heat; that it stopped growing at 41° C. As we could easily increase the temperature of the tissue to any degree, at any rate to 44° C., without hurting the body materially, the possibilities were obvious. Unfortunately the results did not come up to expectation. My friend, Doctor Eitner, who was one of the first to use diathermia in gonorrhea, told me, when I saw him in Vienna, "that he had given up this method." The reason for this failure seems to be the fact that we cannot easily reach all the affected parts. Granting that we can destroy most of the microbes, the remaining ones developed quickly, as microbes do in infected pasteurized milk. There are some authors who state that by prolonging the single session to three quarters of an hour or more, their results are very good; I have had no personal experience, and shall therefore not discuss this point. What I have tried has taught me not to use diathermia in acute and subacute infections of joints. This experience has been quite general as far as the baking was concerned, and I cannot see the difference as far as the result goes.

In arthritis of long standing, especially in old people, the results are often surprisingly good. As many joints are affected at the same time, the treatment is limited in private practice, as it is necessary to treat each joint separately, which means a long session.

I cannot cover the entire field in the restricted space at my disposal, therefore I must content myself if I have aroused your interest in this remarkable therapeutic agent.

161 West Eighty-sixth Street.

Treatment of Osteomalacia.—Alfred C. Crofton (*American Medicine*, November, 1916) recommends phosphates administered in codliver oil in doses of one mgm. of phosphorus to the teaspoonful, two or three times a day. It may also be given in the dose of 0.01 gram in pills or in chocolate coated tablets. Calcium phosphate may be given in capsule form, one gram two or three times a day. Saturation with atropine is recommended by some authors. It is best to begin with 1/200 grain two or three times a day and increase. If of long duration, cachexia develops with diarrhea, extreme wasting, and marasmus. In these cases iron and arsenic should be used.

EYE STRAIN.*

By Isaac Hartshorne, B. A., M. D.,
New York,
Assistant Ophthalmic Surgeon, Manhattan Eye, Ear, and Throat Hospital; Adjunct Ophthalmologist, Staten Island Hospital, Staten Island.

Why is eye strain the least talked of subject in medicine, and why does the subject seem to excite little or no interest when presented? Perhaps it is partly because eye strain is the result of one or more anatomical anomalies; a condition and not a disease; a physiological malfunction which cannot be cured, i. e., cured in the sense of removal without more or less permanent mechanical assistance. Perhaps, also, because the general practitioner has so much else to attend that he obtains only a small knowledge of the mechanism and physiology of vision. Yet fully ninety-five per cent. of the work of the ophthalmologist is either directly or indirectly due to eye strain. And to this may be added all the fitting of glasses done by optometrists and opticians and the mercantile distribution of glasses by advertising quacks and the five and ten cent stores.

As the slogan of modern medicine seems to be "Cooperation for the sake of Prevention," the excuse for this contribution is an effort to direct the attention of the general practitioner to a field of helpfulness on the part of the ophthalmologist.

The function of the ocular system is to receive impressions of objects in space and to transmit those impressions to the brain for interpretation. These impressions are produced by stimulation of the retina by that form of energy we call light. The ciliary muscle, or muscle of accommodation, is in almost constant activity during waking hours, in the effort to clarify retinal images. This activity is particularly marked in the hyperopic eye where no retinal image is clearly defined except through action of the ciliary muscle. Myopes cannot aid vision through ciliary activity, and consequently all retinal images in myopes are blurred. Fully ninety-five per cent. of all persons have more or less astigmatism, i. e., irregularity in the curvature of the refractive media producing irregularly shaped retinal images which are extremely irritating to the retina itself and also to the cerebral centres of interpretation. Low hyperopic errors are easily overcome by action of the ciliary muscle, and the effort to see better being stimulated by fair vision, results in muscular fatigue or hypertrophy, or both; so that the patient with 20/15 vision is often suffering greatly from eye strain; whereas in high errors of refraction the ciliary muscle soon learns that it cannot overcome the defect, and the poor vision which results is associated with blurred images of irregular diffusion which persist in irritating the retina. As the great majority of both hyperopic and myopic eyes are complicated with astigmatism, we can readily see that in most cases we are dealing with a combined effect of muscular fatigue and retinal irritation.

Twelve muscles are required to balance the two eyes so that all images will fall on corresponding retinal areas and thus maintain binocular vision When one or more of these muscles is weaker than the others, our sense of fusion requires it to keep up with the stronger muscles in the effort to maintain binocular vision, thereby calling forth an abnormally large amount of nerve force to the weaker muscles.

To quote from my previous article on this subject (1): "It becomes evident, therefore, that the reasons for eye strain are hypertrophy, fatigue, and congestion of the ciliary muscles in their constant effort to produce clear vision; retinal irritation from circles of diffusion, made worse by irregularity in the presence of astigmatism; and extrinsic muscular hypertrophy and fatigue in the struggle to maintain binocular vision."

As I wish to draw attention particularly to the effect of eye strain on the eyes themselves and also on other organs of the body, I should like to go over the nerve elements involved in the ocular mechanism, with special reference to the part played by the sympathetic system. This I take mostly from Gray's *Anatomy*.

Of the twelve pairs of cranial nerves, the second, third, fourth, and sixth are devoted wholly to the eye and its appendages, while the fifth plays the important part of sensory function.

The second or optic nerve, after entering the orbit, pierces the scleral and choroidal coats of the eyeball and expands to form the retina. Its function is purely visual in that it transmits to the cerebral centres of vision the exact impressions made upon the retina through the refractive media of the eye.

The third nerve, or motor oculi, sends voluntary motor fibres to all the extrinsic ocular muscles, except the superior oblique and the external rectus. While passing through the cavernous sinus, it receives a few sensory fibres from the ophthalmic division of the fifth nerve and a definite anastomosis from the cavernous plexus of the sympathetic. The branch of the third nerve which supplies the inferior oblique muscle, gives off a twig which is the motor root of the lenticular ganglion.

The fourth nerve is the motor nerve of the superior oblique muscle, and like the third nerve has an anastomosis with the sympathetic from the cavernous plexus, and also receives sensory fibres from the first or ophthalmic branch of the fifth nerve.

The sixth nerve supplies the external rectus muscle and receives its sympathetic fibres from the carotid plexus.

The first division of the fifth nerve given off from the Gasserian ganglion is purely sensory and is called the ophthalmic nerve. It receives sympathetic fibres from the cavernous plexus and has three branches:

1. The lacrymal enters the lacrymal gland and has anastomoses with the orbital branch of the superior maxillary and with the facial nerves.

2. The frontal divides into the supratrochlear and the supraorbital, which are distributed to the forehead, eyelids, and scalp, and communicate with the infratrochlear and the facial nerves.

3. The nasal has several branches. Those of importance in this discussion are the *ganglionic*, which enter the lenticular ganglion to form its sensory

*Read before the joint meeting of the Medical Association of the Greater City of New York and the Richmond County Medical Society, at St. George, Staten Island, June 5, 1916.

root, and the *long ciliary nerves* (two or three) which pierce the sclerotic near the optic nerve and pass forward in the eyeball to be distributed to the ciliary muscle and iris. The nasal also sends sensory fibres to the conjunctiva, caruncle, lacrymal gland, the upper eyelid, forehead, and the root of the nose, and also to the nasal septum and turbinate bones and the tip of the nose.

Please note particularly the ciliary or lenticular ganglion. This small reddish body is in the back of the orbit, external to the optic nerve, and has three roots:

1. A motor root from the motor oculi nerve;
2. A sensory root from the nasal branch of the first division of the fifth nerve; and
3. A sympathetic root from the cavernous plexus.

This ganglion gives off ten to twelve short ciliary nerves which pass forward in two bundles above and below the optic nerve and in close relation to the long ciliary nerves noted above. They pierce the sclerotic and pass between the scleral and choroidal coats of the eyeball to be distributed to the iris and ciliary muscle.

The sympathetic system consists of two great gangliated cords extending the whole length of the vertebral column. The two cords are connected above with two plexuses which enter the cranium and unite with the fifth cranial nerves; below they are joined together in a loop over the coccyx. Each ganglion has an afferent and efferent connection with the anterior primary division of the corresponding spinal nerve. This extensive system, through its ganglia and series of plexuses, provides a switchboard connection between the various organs, and it is supposed that a sympathetic relation is thus maintained between different organs. The chief functions of the sympathetic nerves are vasomotor, trophic, secretory, and control of smooth or involuntary muscles.

I have gone into these neurological details in order to recall the close relations between the motor and sensory supply of the ocular mechanism and the sympathetic system. Much has been written about ocular symptoms complicating aural and nasal diseases, and in May, 1913, Dr. William H. Haskin (2) made a contribution of distinct value in that he brought to light the probability that as the majority of ocular symptoms associated with disease of the nasal sinuses are due to vasomotor disturbances, and as the sympathetic nerves are the vasomotor nerves, hence we have a "most reasonable explanation for most of these manifestations in that they are caused by irritation of the (sympathetic) system."

It is common knowledge that stimulation of the third nerve causes contraction of the pupil, and that stimulation of the sympathetic causes its dilatation. It may also be noted that many patients suffering from eye strain have dilated pupils. The fifth nerve is the sensory means of transit of ocular malfunction, either as pain or photophobia from retinal irritation or from irregular and diffused retinal images, or as pain from fatigue of ocular muscles, both ciliary and extrinsic; and it is through the numerous communications between the sympathetic system and the motor and sensory nerves of the eye, as already noted, that the ocular effort to secure clear vision in the presence of slight refractive errors; or else the distorted retinal images persisting as such through failure of the refractive apparatus to clarify them, result sometimes in headaches as referred pain; or sleepiness as fatigue; or in chronic inflammatory conditions of the lids and conjunctiva—including blepharitis, hordeola, chalazia, etc., as vasomotor and trophic disturbances; and sometimes in the malfunction of distant organs, producing such symptoms as vertigo, indigestion, anorexia, insomnia, constipation, car sickness, nausea, and vomiting.

Epiphora is quite a common eye strain symptom, which is doubtless due in part to irritation of the sympathetic secretory function; and can it not be argued that the secretory function in other glandular organs may be similarly affected by the same source of irritation? Epiphora, as an eye strain symptom, is also at times due to chronic inflammation of the lids and conjunctiva in the region of the tear duct openings producing a mechanical obstruction to the outflow of tears. This is due to a vasomotor and trophic disturbance—again a sympathetic irritation.

Dr. W. W. Kahn (3), of Detroit, recently published a paper entitled The Systemic Diseases Caused by Eye Strain, in which he has interestingly tabulated the percentage of recoveries from various symptoms of systemic malfunction after accurate correction of the refractive error of the patients coming to him in one year. The value of this paper by Kahn is that it has grouped several symptoms of the malfunction of various organs evidently produced by some ocular malfunction, as evidenced by the definite relief given by correct glasses. The every day work of those attempting to do therapeutic refraction is so regularly attended by experiences similar to those reported by Kahn that we often forget that the ocular cause of much systemic malfunction may have been passed unnoticed by the general practitioner.

While mastering the field of pathology and studying the benefits to be derived by the patient through the mechanics of surgery, let us remember the assertion of Dr. Richard Cabot, that four fifths of human ailments are functional and only one fifth organic. Let us also remember that probably most functional disorder is at least partly due to some irritation of the sympathetic system. That ocular malfunction is a definite and frequent source of sympathetic irritation, resulting in symptoms of distant organic disorder, is being demonstrated daily by the careful refractionists. Hence, also, a large part of refraction work may become preventive by correcting the eye strain as soon as the earliest symptom of malfunction appears.

To consider the scientific art of refraction, the proper use of cycloplegics, the various elements that make up an optic prescription, the necessity of having the prescription accurately filled and carefully fitted to and worn by the patient in the effort to secure the results suggested, would require a separate paper.

Therefore, in conclusion, and to quote again from my previous article on this subject (1): "When symptoms of malfunction of one organ or system persist after treatment of all obvious disorders, we

have no right to lay it to nervousness or idiosyncrasy, or even to call the condition obscure, until the function of every other organ has been carefully tested and corrected. The constant use of the eyes during waking hours, and the demand for and frequently great waste of nerve force in their use, call for a careful ocular correction in all cases of functional disorder possibly due to some reflex irritation or leakage of nerve force."

105 WEST FORTIETH STREET.

A NEW METHOD FOR INTRASPINOUS TREATMENT OF NEURAL SYPHILIS WITH MERCURY.*

BY MAURICE F. LAUTMAN, M. D.,
Hot Springs, Ark.,
Medical Director, Leo N. Levi Memorial Hospital.

A PRELIMINARY REPORT.

Intraspinous therapy now occupies a well established position in the treatment of syphilitic affections of the central nervous system. Since Swift and Ellis, in 1912, demonstrated the possibilities of intraspinous medication with the serum obtained from patients shortly after the intravenous administration of salvarsan, various preparations have been used, such as serum to which small quantities of salvarsan have been added, neosalvarsan in small doses and weak concentration, and mercurialized serum. These methods have met with varying degrees of success, but, in general, reports show that successes have been attained with the intraspinous treatment of cases of nervous syphilis which had not yielded, in the slightest degree, to systemic specific medication.

It is too soon to draw definite conclusions concerning the permanency of the results. Our standard for measuring the efficacy of any treatment for nervous syphilis must therefore, for the present, be gauged by, 1, the apparent extent of clinical improvement; 2, the arrest of further progress of symptoms; as well as, 3, the reduction in the number of cells, the quantity of globulin, and change of a positive Wassermann to a negative in the spinal fluid, and conversely any method which produces a negative serology in addition to improvement or arrest of the clinical symptoms, may, in the light of our present knowledge, be deemed efficient.

A brief review of the methods now in use shows that in the case of autosalvarsanized serum the amount of specific medication introduced intraduraly is so extremely intangible that it requires a large number of injections to produce results. And the same holds true for the use of serum to which small quantities of salvarsan have been added, or the use of neosalvarsan in weakly concentrated solutions. The direct applications of mercury is theoretically of value, although it would seem from the reports on the method as it is used today that the effects on the Wassermann reaction are not as brilliant as could be desired.

The method about to be described offers nothing startlingly new, inasmuch as it embodies three more or less well known principles. It is to the simultaneous employment of these three principles, however, that I ascribe the excellent results to be related.

1. The first principle requires recognition of the known fact that the serums of patients under mercurial treatment contain infinitesimal though determinable quantities of mercury, the mercurial content being more or less proportional to the intensity with which the drug is pushed. To this serum I have given the name of automercurialized serum.

2. The second factor is more or less theoretical, though to me it seems quite plausible. It assumes that the reason that remedies or dyes administered into the general circulation do not reach the intradural space is because the cerebrospinal fluid is formed by a process of osmosis through the choroid plexuses. The osmosis takes place very slowly or not at all when the pressure in the two systems is equal, but the formation of a negative pressure in the spinal canal by removal of the cerebrospinal fluid would favor the osmosis of drugs from the general into the spinal circulation. This probably accounts for the beneficial results in the treatment of mild syphilitic central nervous involvement, in which lumbar puncture was regularly performed following the intravenous administration of salvarsan.[1] Animal experiments are now in progress in an effort to demonstrate this point.

3. The third principle rests on the supposition that a soluble organic salt of mercury would be less irritating and possess better penetrative powers than an inorganic preparation. As Byrnes[2] points out, when an inorganic salt of mercury comes in contact with protein matter a coagulative process takes place with the formation of the insoluble albuminate of mercury. In order to obviate this I decided to employ a mercurial salt which in solution would be miscible with blood serum without being changed into the albuminate. I found the benzoate of mercury admirably suited to fulfill this requirement.

Mercuric benzoate is the mercuric salt of benzoic acid, having the formula $Hg(C_6H_5COO)+2\ H_2O$, which is readily soluble in normal saline in the quantities necessary for intradural administration, this solution being miscible in any proportion with blood serum without the formation of a precipitate. For the past six months I have been using this salt intramuscularly and have obtained apparently good results in some cases.

To summarize briefly then at this point, the method consists in pushing mercury to the point of tolerance, obtaining the blood serum, reinforcing this by the addition of a solution of mercuric benzoate in normal saline, removal of as much spinal fluid as can possibly be obtained by lumbar puncture, and injecting intradurally the serum mercury preparation. The quantity of fluid injected should be less than the

amount of spinal fluid withdrawn so as to create a negative pressure within the dural cavity. To saturate a patient with the mercury I give daily inunctions of one fourth of an ounce of fifty per cent mercurial ointment, supplemented by triweekly intramuscular injections of any one of the mercurial salts. These procedures are continued until the first evidences of ptyalism appear (foul breath, gingivitis, cramps, etc.), when thirty c. c. of blood are removed by venipuncture. The rest of the technic is similar to that used in the Swift and Ellis method:

1. The blood is allowed to clot and the ten or fifteen c. c. of serum obtained is pipeted off and
2. Centrifugated to remove all the blood cells.
3. One c. c. of a solution of one grain of mercury benzoate in twenty-five c. c.[3] normal saline and is placed in a clean test tube and boiled. If on cooling this solution becomes turbid, it should be discarded and another c. c. of the solution boiled up in the same tube.[4] If this remains clear on cooling,
4. The clear serum is added and the preparation is mixed well.
5. It is then heated at 56° C. for half an hour and
6. Administered, by gravity, at body temperature.

The method of administering the serum is essentially the same as that recommended by Swift and Ellis. The puncture is performed with the patient lying in bed with the knees drawn up, and head flexed as far as possible, and as much fluid removed as can be obtained.[5] The patient is then instructed to extend the head and limbs and the serum is administered. After the injection the patient should lie flat on his back (without a pillow) for three hours, and the foot of the bed may be elevated for the first half hour.

RESULTS.

I have used the method in eighteen cases, though the present writing contains the report of the first ten cases which completed the course of injections. I admit that this number is extremely limited to furnish any positive conclusions, but owing to the fact that the cases are unselected and that the results have proved so uniformly and rapidly favorable, I have not the slightest hesitation in recommending the procedure for the treatment of syphilis of the central nervous system in cases where intensive systemic antiluetic treatment has failed to influence the nervous symptoms or the spinal serology.

Case I. Tabes dorsalis. Mrs. F. S., was forty-one years old, widow and housewife. No knowledge of date of infection. Denied initial lesion, secondary or teritary manifestations. Shooting pains in legs for sixteen years. Gastric disturbance for twelve years. Eight years ago, suddenly lost use of legs and was in bed for two years. After this patient walked with difficulty, legs and feet were numb. Girdle sensation for past eight years. Gastric crises every week for past two months. Intensive systemic treatment for past eight years. Argyll Robertson, contracted unequal pupils, fissured tongue, marked ataxia of upper and lower extremities, absent deep reflexes, marked Romberg. Hypesthesia of legs and soles of feet. Serology on admission: Blood Wassermann negative. Spinal fluid Wassermann four plus to 0.4 c. c. fluid, globulin one plus, thirty cells per c. mm.

Treatment: Received four intraspinous injections in nine weeks. Two weeks after last treatment spinal Wassermann was negative with one c. c. of fluid, nine cells per c. mm., globulin negative.

Note on discharge: Spinal fluid normal, sensation normal, shooting pains and gastric crises stopped, walked without cane, and up and down stairs with a little support, felt the ground underfoot and could walk in bare feet. Felt better than she had in eight years.

Case II. General paresis. Mr. I. M., was fifty-three years old, married, plumber, initial infection thirty years ago. For past two years patient was irritable and slovenly, neglected business, felt weak and tired easily. Insomnia and bad dreams for past four months. Lost twenty-five pounds in weight. One day before admission, while on his way to Hot Springs, patient had an epileptiform seizure lasting an hour. Facial contortions, hesitating speech, apathy, grandiose ideas, defective recent memory, slovenly attire, tremor of tongue, face, and extremities. Incoordination. Gait very unsteady, marked Romberg. Serology on admission: Blood Wassermann negative, spinal fluid Wassermann four plus to 0.2 c. c., globulin three plus, thirty-two cells per c. mm.

Treatment: Received five injections in six weeks. After the third injection the spinal Wassermann was negative with one c. c. fluid, seven cells per c. mm., globulin one plus. The additional two treatments were given for the sake of thoroughness. Ten days after the last treatment the fluid Wassermann was negative, globulin negative, and showed five cells per c. mm.

Note on discharge: Spinal fluid normal, ate ravenously, sleep undisturbed, memory and mentality apparently perfect. No tremors or incoordination. Could walk a straight line, even with eyes closed. No Romberg, speech good. Felt and acted normally in every way.

Case III. Tabes dorsalis. Mrs. R. W., was forty years old, housewife, and widow. Date of infection could not be elicited. Shooting pains for eight years, numbness, paresthesia, and feeling as if walking on rubber for past four and a half years. Difficulty in walking in the dark and up and down stairs. Walked with cane and had occasional urinary incontinence. Gait ataxic. Incoordination in upper and lower extremities. Hypesthesia of entire lower limbs. Marked Romberg. Deep reflexes absent. Serology on admission: Blood Wassermann negative, spinal fluid Wassermann four plus to 0.6 c. c., globulin two plus, forty-nine cells per c. mm.

Treatment: Received three injections in four weeks. Spinal fluid, seven weeks after last treatment, showed negative Wassermann with one c. c., seven cells per c. mm., globulin one plus.

Note on discharge: Spinal fluid normal, legs felt much stronger, no shooting pains. Walked much better, though still with cane. Sensation in feet improved.

Case IV. Syphilitic meningitis. Mrs. N. S., was twenty-one years old, married, domestic, infected three years ago. Systemic treatment for the past year and a half, very intensive for past four weeks. Intense nocturnal headaches for three years. Eruption on body for three months, since which time headaches had been continually getting worse. Patient practically moribund. Regressing papular syphilide. Retraction of head. Rigidity of neck. Bilateral Kernig and Babinski. Serology on admission: Blood Wassermann negative, spinal fluid pressure markedly increased, fluid turbid, Wassermann four plus to 0.1 c. c., globulin four plus, 1,220 cells per c. mm., ninety per cent. polymorphonuclears, bacteriology negative.

Treatment: Received four injections in twenty-seven days. After the third injection the cells were 120 per c. mm., globulin one plus, Wassermann negative with 0.2 c. c., but positive with larger quantities. Clinically she was normal in every respect and therefore refused further treatment, nor would she permit a spinal puncture after her last injection.

Case V. Spastic paraplegia. Mr. H. R., was fifty-four years old, peddler, married, no recollection of initial lesion or external manifestations of syphilis. A year ago he noticed itching all over body (paresthesia), and a month later feet and legs became numb. Three months later, lost use of left leg, which regained power after two injec-

[3] An accurately weighed out grain of the powdered mercuric benzoate is added to twenty-five c. c. boiling normal saline and boiled until the powder is dissolved. This is placed in a stopped graduate and saline added up to the twenty-five c. c. mark to make up for the moisture lost in evaporation. This solution keeps indefinitely, although if not used frequently, it is best to make up a fresh solution each time.

[4] The turbidity is caused by using a soiled test tube.

[5] When the fluid ceases to run spontaneously, the barrel of a Luer syringe is connected to the needle by a rubber tubing about twelve inches long. If the syringe is now lowered, an additional ten to twenty c. c. of fluid can be obtained. A total of from thirty to fifty c. c. fluid can usually be obtained. I disregard the pressure and have encountered no untoward results from removing all the fluid possible.

tions of salvarsan and thirty-five injections of mercury salicylate. Spastic gait, exaggerated reflexes, double ankle clonus, ataxia, and Romberg. Serology on admission: Blood Wassermann negative, spinal fluid Wassermann four plus to 0.4 c. c., globulin double plus, fifteen cells per c. mm.

Treatment: Received four injections in seven weeks. After the third injection the spinal Wassermann was negative, globulin one plus, seven cells per c. mm. Ten days after the last injection the fluid Wassermann was negative, globulin negative, four cells per c. mm.

Note on discharge: Spinal fluid normal; gait still spastic, though considerably improved. Reflexes normal, exhaustable ankle clonus on left side. No clonus on right side.

Case VI. Tabes dorsalis (incipient). Mr. F. W., was a cook, thirty-five years old, single. Initial lesion ten years ago; no rash, but had severe laryngitis and was literally covered with ulcers six months after infection. Had been taking mercury pills all this time. Symptoms of three years' duration. Complained of headaches and nervousness. For past year had had stiffness and numbness of legs, with difficulty in walking in the dark. Sight poor. Sleeplessness and sexual impotence for three years. Nystagmus, tremor of tongue, face muscles, and hands. Incoordination and adiadokokinesia. Deep reflexes absent. Distinct Romberg. Serology on admission: Blood Wassermann negative, spinal fluid Wassermann four plus to 0.2 c. c., globulin two plus, thirty-two cells per c. mm.

Treatment: Received four injections in thirty-four days. Ten days after the last injection the spinal Wassermann was negative. Globulin negative, six cells per c. mm.

Note on discharge: Spinal fluid normal. No tremors or incoordination. No insomnia or headaches. Felt strong. Knee jerks and Achilles reflex still absent.

Case VII. Tabes dorsalis and cerebrospinal syphilis. Mr. C. P., was a cutter, forty-one years old, single. Initial lesion nine years ago. Mild secondaries. Treatment begun three weeks after infection and consisted of seventeen intravenous injections of salvarsan, thirty injections of mercury salicylate, mercury and potassium iodide by mouth. Symptoms dated for one year and consisted of girdle sensations, vomiting attacks without apparent cause, diminished sexual potency, pains in legs, failing memory, an attack of diplopia, and impaired hearing. Slight tremor of fingers, absent knee and Achilles jerks, distinct incoordination and Romberg. Serology on admission: Blood Wassermann negative, spinal fluid Wassermann four plus to one c. c., globulin one plus, nineteen cells per c. mm.

Treatment: Received four injections in one month. After the last treatment the spinal fluid Wassermann and globulin were negative and there were two cells per c. mm.

Note on discharge: With exception of pains in feet (flatfeet), patient felt and acted normally. Knee jerk obtained under reinforcement; spinal fluid normal.

Case VIII. Tabetoparesis. Mr. I. H., was a switchman, forty-five years old, married. Initial lesion twenty-three years ago, followed by sores in mouth. No treatment till three years ago, since when had had three injections of salvarsan. Began to tire easily and had lightning pains in legs three years ago, and shortly after, left leg was almost completely paralyzed, but had gradually improved. Failing memory and irritable temperament (avoided company and conversation) for past two years. Had girdle sensations and "head felt like it had a hat on" for two years. Sexual impotence and urinary incontinence for one year. Slept poorly and had several numb areas on body. Noticed difficulty in pronouncing words. Tremor of face and tongue, dysarthria, Argyll Robertson pupils. Incoordination of upper and lower extremities. Absent knee and Achilles jerks; plantar reflex diminished. Tabetic gait. Could walk straight line. Marked Romberg. Hypesthesia of left leg and upper left quadrant of abdomen. Serology on admission: Blood Wassermann negative, spinal fluid Wassermann four plus to 0.2 c. c., globulin one plus, twenty-one cells per c. mm.

Treatment: Received six injections in forty-four days. After the last treatment the spinal Wassermann was negative with one c. c.; globulin was negative; four cells per c. mm.

Note on discharge: Spinal fluid normal. Gait still unsteady and deep reflexes absent. No girdle sensations or urinary disturbances. Patient in excellent spirits and felt very well.

Case IX. Tabes dorsalis. Mr. J. W., was a cook, forty-two years old, single. Initial lesion followed by sore throat, twenty-five years ago. Had no treatment of any kind. No trouble till eighteen months ago, since when had had gastric crises, difficulty in urinating, pains in back shooting into legs, diplopia and failing vision, and sexual impotence. Tired easily and felt weak. Irregular, dilated pupils, did not react to light. Deep reflexes absent. Marked Romberg and incoordination of upper and lower extremities. Unsteady gait. Serology on admission: Blood Wassermann negative, spinal fluid Wassermann four plus to 0.4 c. c., eighty cells per c. mm., globulin two plus.

Treatment: Received six injections in forty-eight days. After the last treatment the spinal Wassermann was negative with one c. c. of fluid, globulin negative, and eight cells per c. mm.

Note on discharge: Spinal fluid normal, gastric crises, leg pains, and urinary troubles disappeared. Deep reflexes absent. Felt pretty well, but still a little weak.

Case X. Cerebrospinal syphilis; double optic neuritis. Mr. H. S., was a peddler, forty-three years old, married. Initial lesion, twenty-one years ago. No secondaries. No constitutional treatment. Ulcers on legs four years ago. Shooting pains in legs for two years. Noticed that left eye was blind, five months ago. Vision failing in right eye for two weeks. Condition progressing rapidly. Left eye had light perception; right eye vision two fifths of normal. Reflex pupillary rigidity. Unsteady gait, Romberg, and ataxia. Knee jerks not elicited. Serology on admission: Blood Wassermann negative, spinal fluid Wassermann four plus to 0.1 c. c., globulin four plus, reduction to Fehling's absent, eighty cells per c. mm.

Treatment: Received four injections in forty-nine days, left the hospital, and returned after three months for two treatments. After the last injection, spinal fluid showed a negative Wassermann, negative globulin, and contained eight cells per c. mm.

Note on discharge: Spinal fluid normal. No clinical improvement, but there had been no further impairment in vision. This patient had been under observation for nine months.

Of the remaining eight cases, four are still under treatment and four would not continue treatment. Three had advanced tabes, two were ordinary tabetics, two had general paresis, and one had cerebrospinal syphilis. These cases showed varying degrees of clinical and serological improvement according to the number of treatments each received, and while all of them showed a lowered cell count and a less positive or negative Wassermann reaction with the usual quantities of fluid, no case is reported as a serological cure unless the cell count was normal and the Wassermann test gave complete hemolysis when one c. c. of fluid was used.

SUMMARY.

This communication describes a method of treatment of syphilis of the central nervous system and a detailed account of the first ten cases in which the method was applied.

The cases were unselected and, happily, embrace almost all the forms in which neural syphilis manifests itself. The diagnosis in all the cases was based upon unmistakable clinical symptoms and a positive Wassermann, increased cell and globulin content in the cerebrospinal fluid. In all the cases, after from three to six injections the spinal fluid was rendered normal. The extent of clinical improvement and the restoration to economic efficiency seems to depend upon the extent of degeneration at the time the treatment was instituted. In no case was there further deterioration during or after the treatment. Neither was there any case in which the spinal serology could not be influenced. In fact, when a case comes under treatment, if the smallest quantity of spinal fluid which gives complete inhibition is ascertained, and then gradually increasing amounts of fluid are used in doing the Wassermann, it will be seen that after each treatment it will require a larger amount of fluid to give complete inhibition.

It is granted that the number of cases treated is so

extremely small and the period of observation so short that no definite statement can be made regarding the absolute value or merits of the method. The results in the cases treated were so uniformly favorable, however, and in some cases so brilliant, that I have not the least hesitation in recommending the method for the treatment of syphilis of the central nervous system.

THE FALLACY OF FALLACIES ABOUT TUBERCULOSIS.

A Criticism of Doctor Fishberg's Paper in the New York Medical Journal *for December 2, 1916,*

By A. Robin, M. D.,
Wilmington, Del.,
Medical Director, Hope Farm Sanitorium for Consumptives.

Now and then some one who is outside the great movement against the white plague steps into the limelight and indulges in a few oratorical flings at the "crusaders." The flings do not hurt the crusaders, nor do they materially affect the worldwide crusade; but they furnish some sort of ammunition to the objectors, give courage to a lot of Rips who slumber while dreaming the dreams of the past, and, what is worse, disturb the mind of the layman whose judgment is easily distorted by conflicting opinions and whose natural inclination is to follow the leadership of those who are opposed to restrictive measures of any kind. For such people Doctor Fishberg's article will serve as a pillar of support.

Doctor Fishberg dismisses many a live medical problem by the convenient term "fallacy." To the "fallacies" that he discovered in relation to tuberculosis we will attempt to add one more, and that is the fallacy of his reasoning.

First, let us dispose of the fallacy that "over ninety per cent. of human beings in large cities have been infected during their lifetime," and that "it is difficult to find a person who does not react to tuberculin, or in whom active, latent, or healed tuberculous lesions cannot be found when a careful autopsy is made."

In the first place, this is not exactly correct. The fallacy arose from some European statistics which seemed to indicate that in certain hospitals over ninety per cent. of the autopsies revealed old scars in the lungs. Whether these scars were due to tuberculosis or to some other conditions is not certain, and I am not aware of any statistics based on a careful histological study of these incriminating scars. I do not care to take the time to hunt up statistical data, but my impression is that in this country autopsies show evidence of old tuberculous lesions in from sixty to seventy-five per cent., which is much nearer the truth. Equally fallacious is the statement that almost all children react to tuberculin. My own experience has been that only from sixty to seventy-five per cent. react. And here again we must bear in mind that in a certain proportion of positive cases, the children may possess an inherent or acquired sensitiveness to tuberculin without having suffered a tuberculous infection.

May I say in passing that our knowledge of the large group of acidfast bacilli to which Bacillus tuberculosis belongs is far from complete, and it may well be that certain varieties of this group produce mild infections which are not true tuberculosis as we understand it clinically, and which may induce a sensitiveness to tuberculin? This should occasion no more surprise than the fact that the serum of normal persons who never have had typhoid fever may give a positive Widal reaction in certain dilutions.

If my reasoning is correct then there is a considerable number of people (at least twenty-five per cent.) who are free from tuberculous infection and are in danger of such infection *when exposed to a sufficient number of implantations.*

The impression conveyed, perhaps unintentionally, by Doctor Fishberg is that tuberculosis is a comparatively trivial infection from which a great many persons recover spontaneously without any treatment whatever, and even despite treatment.

I wish it were so, but the 200,000 graves that are filled up annually in this country by victims from tuberculosis do not indicate any such benign character for this disease. In fact, it seems that when the tubercle bacillus has made appreciable inroads into the tissues, the patient has a mighty hard time to manage to live. But let us assume for the sake of argument that every one of us has, as some German savant expressed it, "a bit of tuberculosis," does that carry with it the assumption that we are immune? Doctor Fishberg thinks it does, and gives us the assurance that "adults are safe against infection with tubercle bacilli" (of course, children not being "safe" should still be protected). He assumes that the million or so consumptives in this country have acquired the infection in childhood and the disease later. He stands almost alone in this sweeping assertion. While it is generally believed that in a great many cases the infection is acquired in childhood, no one with authority to speak on the subject would support the doctor's contention. But assuming that the incidence of childhood infection is as universal as Doctor Fishberg maintains, we are still not at all sure that reinfection is impossible. I am unaware that "recent research has shown, however, that tuberculosis is no exception to the rule in pathology, that one attack of a specific disease immunizes against further and renewed infection with the same virus."

In the first place, "the rule" in pathology is exactly the other way, or, what is more correct, there is no such rule. Tonsillitis, influenza, pneumonia, diphtheria, erysipelas, and a host of septic infections do not confer any lasting immunity. Even typhoid fever and the eruptive fevers which do confer a lifelong immunity may attack certain persons more than once. Gonorrhea can certainly be acquired many times during a lifetime, and a recent chancre in an old syphilitic is by no means rare. We are not in a position to make any rule free from numerous exceptions, but were we permitted to generalize, I should say that infections characterized by bacteriemia confer a lifelong immunity, while in those in which the bacteria are localized and the toxemia is the underlying factor, the immunity is of short duration. Tuberculosis being a toxemic infection belongs to the latter group, and clinical evi-

dence as well as experimental data bear out this assertion, Doctor Fishberg to the contrary notwithstanding.

The doctor belittles "the warnings given to consumptives that they must not expectorate indiscriminately because they were likely to infect others, and may reinfect themselves, and thus acquire new lesions in parts of the lungs hitherto unaffected." The warnings are perfectly timely and should be heeded. Tuberculosis spreads by extension, probably through the lymphatics. Successive areas of lung tissue become involved on one or both sides, at the apex, the base, or the roots; the larynx and at times the pharynx become affected owing to the contact with germ laden sputum; tuberculous ulceration of the intestines results from sputum that is swallowed: other organs such as the kidneys, the spleen, and the pelvic organs are frequently infected. If all these pathological changes, dependent as they are on dissemination of tubercle bacilli, are not the result of reinfection, how are they brought about? And if a patient can be reinfected by his own bacilli, is it not reasonable to limit as far as possible the reintroduction of these bacilli? And if a consumptive can reinfect himself, why cannot he infect others? After all, the incidence of infection is, all other things being equal, as much a matter of dose as the introduction of a poison. A person may be able to resist the implantation of a certain number of tubercle bacilli, but when that number is multiplied a hundredfold or the implantation is repeated frequently the resistance is broken down. An advanced consumptive with his half million tubercle bacilli thrown off every twenty-four hours is a greater menace to himself and others than one in early stages who expectorates only a relatively small number of bacilli. Likewise, a consumptive who takes care of his sputum is far less dangerous than one who does not, even if there is still some danger from droplet infection. There is a chance that the fine droplets may contain a few stray tubercle bacilli which have become disentangled from the main mass of sputum and remained in the mouth or nose; there is absolute certainty that the sputum mass does contain these tubercle bacilli in large numbers. There is a chance that tubercle bacilli enclosed in minute droplets of moist sputum will lodge in the mouth and infect the susceptible victim by way of the tonsils or digestive tract; there is a certainty that dried sputum will become pulverized and in the very best state for direct inhalation. There is still another reason why advanced consumptives should take care of their sputum, even in sanatoriums where they are in contact with other consumptives. We know that the worse feature of tuberculosis, the condition that seals the patient's doom, is the mixed infection with pyogenic cocci. They are not the ordinary tame cocci which we find so generally distributed on body surfaces. By virtue of their sojourn in a diseased body and also, perhaps, through symbiosis, they have become highly virulent, giving rise to the marked septic conditions from which the advanced consumptive suffers. It is not right to expose another fellow patient in the earlier stages of the disease to infection with these virulent cocci. So, then, our "crusaders" are not so ludicrous when they advocate the proper care of the consumptive's sputum.

Further to strengthen his case against modern tuberculosis prophylaxis, Doctor Fishberg presents the clinical evidence, to wit: That doctors and nurses who come in contact with consumptives, "do not suffer from tuberculosis more than others," and that conjugal phthisis is "exceedingly rare." Of all fallacies this sort of argument is the most fallacious. We have known doctors, nurses, husbands, and wives who contracted tuberculosis, but we are in no position to assert categorically that they were infected by their patients or mates, or through other sources. Who can say? As to doctors and nurses coming in contact with consumptives in hospitals, their chances of infection are far less than in private practice, particularly among the poor, since in hospitals they come in contact with moist sputum, the least prolific source of aerogenous infection.

Doctor Fishberg accounts for the rarity of infection among doctors and nurses as well as for conjugal infection by the fact that these persons are immune by virtue of a preexisting infection. How will he explain their freedom from tuberculous disease? By immunity? What became of the immunity of the afflicted? It is puerile to juggle with these obscure phenomena in an effort to bolster up a preconceived notion. This sort of reasoning will lead us to the conclusion that pneumonia is noninfectious because doctors and nurses rarely contract the disease while on duty, but do contract it occasionally when they go to a party. In many instances only one case of typhoid fever, scarlet fever, or diphtheria develops in a family, and during the recent epidemic of poliomyelitis there were relatively few family infections. Are the others immune, or have they escaped infection by the same chance by which some lucky soldier on the battlefield escapes being hit by a bullet? Who knows? What we do know is that every bacterial disease is communicable directly or indirectly to persons who are thoroughly exposed and who are susceptible at the time, provided that the virulence and the dose of the infective agent are sufficient to produce disease. This general principle underlies our conceptions of all transmissible diseases. As to the application of the principle to individual cases our ground is not so firm, since many of the factors involved cannot be determined.

Viewed from this standpoint every consumptive with an open lesion is a carrier of infection, and, therefore, a menace to others, to the extent to which he is either a potential or an active carrier. Whether he infects children or adults, whether in his life's journey he comes in contact with immune or susceptible people, is really beside the question, since it is not in our power to predetermine these factors. Therefore, there is every reason to "employ the strenuous measures which have been taken by the authorities, as well as by the members of our profession during recent years," if we are to make any headway in our campaign against the great white plague.

Concerning the "fallacies in diagnosis," Doctor Fishberg takes the astounding position that since in

a certain number of cases of tuberculosis a fatal issue will result notwithstanding treatment and in a certain larger proportion patients will recover without medical attention, early diagnosis is unnecessary. Why make a diagnosis at all? Why not resort to the convenient label of "chronic bronchitis," or a "run down system," as our forefathers did and some doctors are still doing? There is certainly much less trouble in such a course. Is such a position reasonable? Let us for a moment forget the favorable results obtained by sanatoriums in the treatment of early tuberculosis. Is it reasonable to assume that in a disease which affects general metabolism as profoundly as does tuberculosis early rational treatment is of no benefit? And if it is, are the patient's chances for recovery not greater when such treatment is instituted at the earliest possible moment? Is not this equally true of other diseases in which the disturbance of metabolism and the resulting toxemia are the chief factors, namely, that the sooner the disease is recognized and proper treatment instituted the better are the patient's chances of either ultimate recovery or prolongation of life? I take issue with Doctor Fishberg when he assumes that the "crusaders" make a diagnosis of incipient tuberculosis on physical signs alone. I know of no authority on the subject who does not insist on the correlation between objective and subjective signs as necessary for a proper diagnosis of early tuberculosis. No one who is at all careful in his work will hazard a positive diagnosis on the presence of impairment, prolonged expiration, or a few rales. But if in addition to these signs there are constitutional symptoms, a diagnosis may be made with reasonable certainty, and in that case the sooner treatment is instituted the better. Deny this and you deny the utility of early rational treatment in nephritis, diabetes, arteriosclerosis, rheumatic conditions, etc.

What is the rational treatment of tuberculosis? Just such as would increase natural resistance of the patient, if he has any. Good food, fresh air, which acts as a tonic, and such symptomatic treatment as may be indicated. If the patient's appetite is lagging, nux vomica before meals will be of considerable help; if digestion is poor, hydrochloric acid will prove of value; if the harassing cough upsets the stomach, disturbs sleep, or favors hemorrhage, a sedative will be of inestimable benefit, and so on. Failure to apply this simple treatment will rob the patient of his chance to get well. The most essential part in the treatment of tuberculosis, however, is the regulation of rest and exercise, a point not generally appreciated. Given a febrile case, even in the earlier stages, exercise will often change an otherwise favorable course to one leading to a fatal issue. On the other hand, in afebrile cases a certain amount of exercise is necessary to stimulate metabolism. A patient with tuberculosis requires the most careful and painstaking supervision, such as can be given only in a well regulated sanatorium. To say that such supervision has no beneficial effect is to deny the value of the practice of medicine in general. As to the use of "creosote, arsenic, iodine, allyl, ichthyol, mercury succinimide, and a host of other drugs," they form no essential part of the treatment, any more than a large number of other drugs employed empirically in other diseases. While here and there a physician may employ them with apparent success, they are not used to any extent in sanatoriums. Even tuberculin is not regarded as a specific, although it has its legitimate place in certain cases.

Sanatoriums are frequently held up to ridicule for assuming to treat tuberculosis in the sense that certain definite remedial agents are employed and unwarranted statements are made. As a matter of fact this is not so, and Doctor Fishberg, as one of our leading authorities on tuberculosis, ought to know that it is not so. The sanatorium, in the first place, takes care of the advanced and incurable consumptive for the same humane reasons which actuate the establishment of institutions for the care of the incurable. In discharging this duty, the sanatorium indirectly segregates the consumptive who would otherwise be a source of infection (to children).

Secondly, the sanatorium places the curable consumptive in the best possible position to get well. No one can tell in any given case whether the patient possesses sufficient resistance to overcome the disease; consequently, when left to himself, with slight resistance, he may lose all chance to make the most of it in his fight against a formidable enemy. The sanatorium helps such a patient to make a successful fight.

Thirdly, the sanatorium is becoming an institution in which advanced work in the study of tuberculosis is carried on to the ultimate benefit of mankind. In this respect it is sufficient to mention the work of the late Doctor Trudeau and his followers to silence the vociferous objectors to these splendid institutions.

In conclusion, I wish to assure the reader that we do not "prohibit school attendance" or institute "prolonged and costly treatment" in the case of the "sickly, underfed child" with "enlarged tracheobronchial glands." We merely suggest open air schools and nourishing food. Just to what "costly treatment" Doctor Fishberg refers I do not know. At the present high cost of food, proper nourishment is perhaps a trifle costly, but less so than subsequent ill health or a funeral. I know of no other "costly treatment."

THE ROLE OF SYPHILIS IN THE INSANE NEGRO.*

By Louis Wender, M. D.,
Washington, D. C.,
Assistant Physician, Government Hospital for the Insane.

Although syphilis has always been a subject of great interest to the medical man, it has especially occupied the attention of investigators since the advent of the various biochemical diagnostic aids and the epoch making discovery of salvarsan by Professor Ehrlich.

It was only natural that the subject of syphilis in the negro should have received its share of attention, and as a result all sorts of unsubstantiated statements have appeared in the literature. Thus,

*Read before the Washington Society of Nervous and Mental Diseases, May 18, 1916.

one writer (1) states that sixty per cent. of the southern negro are infected with syphilis, while another (2) asserts that ninety per cent. of the colored patients who apply at his clinic suffer from this disease. If these statements are to be taken as correct, it is indeed a sad state of affairs for the negro, and evidently does not speak very flatteringly for the so called benefits of the white man's "civilization." It is quite comprehensible that with his gain of freedom the negro should have plunged headlong into so called "civilization," grasping the good and the bad, and so should have fallen a victim to alcohol and syphilis. And, if the latter disease has really laid such hold upon him as the figures lead us to believe, it is time that definite steps were taken to put a check to the evil. This study was prompted by the desire to investigate more closely the prevalence of syphilis in the colored insane.

The material utilized here consists of 106 colored male patients admitted to the Government Hospital for the Insane, Washington, D. C., between July 1, 1914, and June 30, 1915. Inasmuch as all but twenty of these patients were residents of the District of Columbia, the finding ought to throw some light upon the status of the problem in the city of Washington.

GENERAL STATISTICAL CONSIDERATIONS.

Of the 106 cases admitted, fifty-three, or one half, were infected with lues, the diagnoses having been based, aside from the clinical findings, upon positive serological data. The fifty-two syphilitic cases divide themselves further into two groups:

1. Those in which the relationship between the existing psychosis and the syphilis could not be clearly established, twenty-one cases, and,

2. Those who suffered from distinct syphilitic disease of the central nervous system, thirty-two cases. Of the latter group eleven suffered from cerebrospinal syphilis, so called, while the remainder, twenty-one cases, or 18.86 per cent., suffered from general paralysis. When we compare our findings with those of other investigators, our material shows a considerably higher prevalence of syphilis. Ivey (3) finds that twenty-five per cent. of males and twenty-seven per cent. of females suffered from syphilis among 600 colored people (insane) examined by him, while Hindman (4) found only sixteen per cent. of syphilitics among colored insane patients, compared to five or six per cent. among white insane in 1,194 consecutive admissions.

It is significant that our figures should be so high, notwithstanding the fact that all but twenty of our patients were residents of the District of Columbia, for it is quite definitely established that as a whole the Washington negro belongs to a higher social stratum than the average negro. Of the 106 subjects only eight had no education at all, while of the remainder, four had some high school training, eighty-one had attended public school for a number of years, and thirteen only knew how to read and write. From our knowledge of the negro, we should be inclined to the opinion that a chance for an education or even its acquisition does not materially influence his well known sexual promiscuity.

The negro has invaded certain industrial fields to such a marked extent, fields of endeavor which furnish such great opportunities for the transmission of syphilis by nonsexual methods as to cause us to take special notice of the tremendous prevalence of syphilis among this race. We have only to think of the thousands of colored waiters and barbers throughout the country to appreciate the danger.

Of the fifty-two syphilitics thirty-five were married, seventeen were single, while the conjugal state of one is not known.

	Conjugal Condition.			
	Group 1.	*Group 2.* Cerebral Syphilis.	Paresis.	*Total*
Married	11	9	15	35=66.03 per cent.
Single	10	2	5	17=32.75 per cent.
	21	11	20	52

The greatest number of the married patients belonged to Group 2, namely, those suffering from syphilis of the central nervous system.

Age.	*Total admissions.*	*Total syphilitics.*	*Grade I.*	*Grade II.*
1-20 years	7	2	2	..
21-30 years	30	4	3	1
31-40 years	25	21	4	17
41-50 years	20	15	5	10
51-60 years	9	5	1	4
61 years and over	15	6	6	0
	106	52	21	32

While it will be seen that more than one half of our admissions were between the ages of twenty-one and forty years, those infected with syphilis fell mostly between the ages of thirty-one and fifty. This is readily understood when we remember that paresis, at least, which was represented in our material by twenty-one out of the fifty-three, occurs on the average between ten and fifteen years after initial infection. The sins that are committed in the younger days claim their victims in later life, in the form of cerebral syphilis or paresis. All ages are represented. The youngest is seventeen and the oldest is over sixty years old.

History of infection. Only twenty-three of our fifty-two syphilitic patients admitted luetic infection; eight admitted gonorrhea. Four patients who admitted syphilitic infection gave a negative Wassermann. These were treated in the Army and Naval Hospitals, and knowing the danger of the disease, perhaps wanted to get more treatment. It is very seldom that we meet with a patient who is frank about his venereal history. Notwithstanding that many of the objective findings, such as scars on the penis, general adenopathy, scars in the groin from infected glands, are present, the negro patients will always find some sort of an excuse how the thing happened, other than through sexual intercourse.

Serological findings. For some years past all patients admitted to this hospital had the blood examined as a routine, and those patients who show involvement of the central nervous system have the cerebrospinal fluid examined. The diagnosis is in many cases thus cleared up. We encounter syphilitic psychotic disturbances with mental pictures resembling other forms of mental disorder, and considerable depends upon the serological findings for the clearing up of the diagnosis. The following case illustrates a typical alcoholic hallucinosis, but on examination it was found that the patient was suffering from cerebral syphilis.

Case I. J. J. P., was a porter by occupation, aged forty years, married. Medical certificate stated: "Patient heard voices at night and during the day, stated that people were trying to harm him and that he could hear them coming after him. He also stated that he saw dead people who were in front of him, then would vanish as soon as he wanted to talk to them." Status on admission, a poorly nourished colored adult male with irregular pupils, reacting poorly to direct and consensual light and accommodation and diminished reflexes, also suffering from a depressive anxiety state due to hallucinations of a threatening nature both in the visual and auditory fields. History showed that the patient had been married for the past thirteen years, that one stillborn child was the only issue. He gave a history of having had a chancre about twenty-five years ago. He also gave a history of alcoholic indulgence for the past seven years, which he attempted to minimize, but his statement was contradicted by his wife, who stated that he spent most of his earnings on beer and whiskey. A detailed mental examination showed him to be only approximately oriented in all spheres. Comprehended without difficulty what was said to him, but was somewhat retarded in his movements and speech. Was apprehensive and would become lacrymose when relating his hallucinatory experiences. These voices accused him of theft and drunkenness and would call him bad names, curse him, threaten to kill him, etc. His memory for recent and remote events was impaired. Physical examination showed a scar across the neck from a suicidal attempt. The pupils were irregular and reacted poorly to light and accommodation. Tongue was tremulous, face asymmetrical. Aortic sound was accentuated. The liver was enlarged. Diminished deep reflexes. He had a coarse tremor of extended hands. Wassermann reaction with the blood serum was positive; with cerebrospinal fluid the appearance was clear. Wassermann negative, and protein content increased. Cells per c. mm. were fifty-six. With the history of excessive indulgence in alcohol for the past seven years and the mental symptoms, the diagnosis of alcoholic hallucinosis would have readily suggested itself, but the laboratory findings materially aided in clearing this doubtful case, and under active antiluetic treatment in the form of salvarsan and mercury, we were able to reduce practically all the findings to a negative phase, and also to improve his mental picture.

None of the hallucinatory disturbances are manifest now and as a whole he does not display any gross mental symptoms, aside from being a little retarded. He enjoys parole privileges and helps with routine work. Failure to recognize this case in its true light and thus neglect the proper therapeutic measures would have no doubt led to a severer form of cerebral involvement with a worse prognosis.

In spite of so many negative histories we found the following: Forty-five patients gave a complete fixation with their blood to the Wassermann test. In eight cases the fixation varied between a nearly complete positive to weak, thus giving a total of fifty per cent. of our male colored population infected with syphilis. Out of seventy-nine female colored patients we found 30.37 per cent. suffering from syphilis, 20.25 per cent. of whom suffered from syphilitic psychoses. Among our total colored male population, of about 400, twenty per cent. showed syphilitic infection. This great difference in the prevalence of syphilis among the cases reported and the total colored population is to be explained on the ground that so many of those suffering from syphilis of the central nervous system, especially paresis, die within a short period.

In the following cases the blood had to be examined several times in order to clear up the diagnosis. One patient whose blood gave a weak fixation in the Wassermann was admitted for an alcoholic psychosis, during an attack of delirium tremens, and his reaction to the Wassermann tests was weak, but he admitted luetic infection. In another patient a provocative test had to be done in order to clear up the diagnosis. In a young boy, whose Wassermann was negative, but in whom physical examination showed the stigmata of congenital syphilis, the blood became positive after a provocative test was made.

One patient who showed all the physical findings of cerebral syphilis gave a negative Wassermann in the blood, but his cerebrospinal fluid showed that an inflammatory process was going on in the brain. He was placed under antiluetic treatment, receiving mercury and potassium iodide, and his blood continued to remain negative. He acquired a luetic keratitis and therefore received salvarsan intravenously, and his blood became positive and remains so at the present writing. So it will be seen that a negative Wassermann does not exclude syphilis, but means further examinations either by a provocative or a luetin test.

Urinary findings. Although this paper deals with the prevalence of syphilis in the insane negro, I cannot refrain from mentioning that twenty-six cases showed renal involvement. Stengel and Austin (5), in speaking of syphilitic nephritis, mention a chronic form in which syphilis is the etiological factor. It is in the later stages of syphilis that amyloid and interstitial kidneys are common. These authors believe that there exists a parenchymatous type of nephritis due to syphilis, characterized by albumin, hyaline and granular casts, with occasional tendency to produce edema of renal distribution. Out of eighty-four cases of nephritis they found sixty-six with syphilis as a possible cause for the disease. Of the eighteen remaining there existed in eight either an unquestionable history of syphilis or a positive Wassermann, or both. In six no Wassermann was secured, while in four syphilis was definitely excluded. There is no doubt that our cases bear out their statements. The coincidence of syphilis and nephritis in a middle aged man, without apparent cause, suggests that syphilis no doubt is a factor in the chronic form of nephritis, and further study in this direction suggests itself.

As previously stated, the fifty-three syphilitics divide themselves into two groups: Group 1, in which syphilis could not be laid down as the primary etiological cause, twenty cases, and Group 2, in which syphilis played its role in the production of the psychosis, thirty-two cases.

Group 1. The group comprises twenty patients in whom the relationship between the syphilitic infection and the existing mental disorder could not definitely be established. We are unable to state how much syphilis played a role in the production of the mental upset. Two of these patients were imbeciles, in one of whom syphilis was congenital. Here no doubt syphilis played an important part in the causation of the mental defect. In the other it is impossible to state whether the syphilis was congenital or acquired. An important fact in his case is that a half brother was admitted to this hospital some time later suffering from paresis. The diagnosis of dementia præcox was made in twelve out of twenty cases. The causative factor of dementia præcox is still debatable. Although no doubt

there are cases in which certain psychic disturbances enter into the causation of the disease, yet it seems that there are cases of the so called dementia præcox group in which biochemical disturbances have a great influence in precipitating the disorders. We see no reason why a disturbance in the vegetative nervous system or an affection in the complex mechanism of the internal secretory glands could not produce a psychosis as well as it produces certain neuroses. That these systems share in the evils of a systemic syphilitic infection is quite plausible.

Group II. Thirty-two, or 30.15 per cent. of our male colored patients suffered from syphilitic psychoses, and since this disorder manifests itself largely after the thirtieth year, the large percentage of married people among them is explained. It is probable that this high ratio of syphilitic psychoses in our admissions depends to a large extent upon the urgency of hospital care in these cases. We admit many dementia præcox patients whose illness has been going on for years without having been recognized by the family. It is not so with syphilitic disorders of the nervous system. If the family fail to take cognizance of the prodromata, they are bound to notice the disorder within a few months in full display. Whether it is cerebral syphilis or paresis, the disorder cannot escape the ordinary observer, though some of our subjects were not admitted until they fell down with a convulsion while at work, became so amnesic that the police picked them up, or so excited that the family were frightened and asked for protection. This accounts for the very few recoveries in cerebral syphilis and high, rapid mortality in the paretic group. In an examination for the cause of admission in our series of thirty-two cases, only six asked for protection by the police from their own delusions, only a few were sent by the relatives because the patients were unmanageable, while the remainder were committed by strangers, and none were admitted at an early stage of the disease. Consequently we were unable to ascertain the duration of the disease prior to admission to the hospital.

The syphilitic psychoses divide themselves into two great groups, viz., the cerebral syphilitic type and the paretic type, although at times no distinct differentiation could be made out. Some observers differentiate between these two disorders by the Wassermann test in the cerebrospinal fluid, calling all cases with a negative Wassermann in the fluid in all dilutions cerebral syphilis, while those that give a positive Wassermann in the fluid are paretics. But this rule is not infallible. In this series several patients had the laboratory diagnosis of cerebral syphilis and the clinical and mental pictures of general paresis, while others whom we diagnosed to have cerebral syphilis, had a positive Wassermann in the fluid. It is obvious that all available facts, clinical and laboratory, should be utilized before making a diagnosis, for the exact differentiation between cerebral syphilis, so called, and paresis is of great importance therapeutically and prognostically.

Cerebral syphilis. In this group we had 11 cases in the following ages:

31 to 40 years,	7
41 to 50 years,	2
51 to 60 years,	2

The youngest patient was thirty-one and the oldest fifty-five years old, the date of infection being so unreliable that it was not deemed of any value to record it.

While anatomically three distinct groups of cerebral syphilis are recognized, namely, gummatous, meningeal, and endarteritic, clinically apathy, stupor, various degrees of confusion, headache, and local palsies are the most commonly met with symptoms. Confusion was the most common symptom in six of the cases, others suffered from a paranoid state, and one patient's clinical picture resembled catatonic præcox, the diagnosis having been cleared up only by the aid of the laboratory.

Neurological disturbances. Pupillary disturbances, such as loss of reflexes or diminished reflexes, were present in all patients, but irregular pupils were present in only five and unequal pupils in only two patients. Nine patients showed disturbances in tendon reflexes, five having exaggerated, three diminished, and one unequal reflexes due to hemiplegia. There are no better danger signals than the pupil and tendon reflexes, and we have to be on guard for syphilis of the nervous system when we encounter these symptoms. Especially is this true of the pupillary disturbances, for at times they are the first objective signs to appear. It is at this time that active antiluetic treatment in the form of mercury and salvarsan is of the greatest import.

DIAGNOSIS.

It seems that with the present up to date laboratory technic the diagnosis of cerebral syphilis should be an easy task, but at times we meet cases that are atypical, not only in the serological findings, but also in the clinical picture. It is most important to differentiate this disorder from paresis. Although the prognosis for either disease is not bright, yet those of cerebral syphilis have a chance of prolongation of life, and "where there is life, there is hope!" In our series of cerebral syphilis only one patient died, while the mortality of general paresis was far greater than was anticipated: only four out of the twenty are now living.

PROGNOSIS.

The prognosis in this disorder is more favorable with treatment, especially so when the disease is recognized in its early manifestations in the so called gummatous or meningeal type. Several of our patients have given negative serological findings and in some the mental disturbances are gradually improving, and while it is doubtful whether we can do anything where destructive brain changes have taken place, it is a fact that excellent results have been obtained when the disease was recognized early, especially the meningeal and gummatous types.

TREATMENT.

All the aforesaid cases were treated with salvarsan, mercury, and potassium iodide. We not infrequently hear practitioners state that about three doses of 0.6 grams of salvarsan are sufficient to cure syphilis. In our limited experience, whether treating syphilis in general or of the nervous system, we seldom obtained a negative Wassermann with the amount mentioned. One patient received

as many as nine intravenous injections before his blood became negative. Several other patients who suffered from cerebral syphilis required treatment continuously. Three of our patients showed on two occasions negative Wassermann with the blood serum, but when their blood was tested several months later it was again positive. Continuous energetic treatment is therefore obviously necessary, and those who give their patients only a few injections of salvarsan and believe them cured are doing a great deal more harm than good. We had no complication in our intravenous administration of salvarsan or neosalvarsan. The mercury injections seemed to have a deleterious effect on the older patients only, and these had to be treated with arsenical preparations.

With this treatment we were able to reduce most of the laboratory findings to a negative phase, and the mental picture in several has been gradually improving. To be sure, the question of recovery depends upon the amount of damage done to the brain tissue, and amount of mental deterioration the patient has undergone before coming to a hospital of this sort.

The following cases of cerebral syphilis illustrate how, after active antiluetic treatment recovery at the laboratory level became complete, but no improvement resulted in the mental picture.

Case II. N. R., who was admitted in a marked state of confusion which gradually cleared up. The laboratory findings, as well as the neurological picture, were typical of cerebral syphilis. After some treatment the laboratory picture became negative in all phases. However, mentally he still showed no improvement. He received mercury intramuscularly, salvarsan intravenously, and three injections of mercurialized serum intraspinally. His blood was negative on one occasion and became positive again after several months. He was again placed under treatment and blood remained negative the past five months. We had several others of this series whose blood became negative after treatment and positive when treatment was discontinued. It seemed essential to reduce the findings to the negative phase both in the blood and the cerebrospinal fluid before we stopped treatment.

Another patient whose blood became negative but whose cerebrospinal fluid had been continually positive, showed on recent examination that his blood was positive and remained so in spite of all treatment, although there was some improvement in his mental condition.

In all of our treated cerebral syphilitic cases we were able to obtain some degree of improvement in the clinical as well as in the laboratory picture. However, treatment should be complete. The case cited below shows the error in an incomplete treatment of cerebral syphilis.

Case III. J. W. T., was fifty-five years old on admission. Medical certificate stated: "Present symptoms—marked depression, delusions, mental excitement, and violence." On admission, clouding of consciousness was present; he was confused and totally disoriented. Nothing of importance in family history. Personal history: Patient an ordinary colored man, common laborer by occupation. Was married seventeen years ago, but there were only two stillbirths from this union. Gave a history of gonorrhea about twenty years ago. Stated he was a moderate user of alcohol. Present trouble started when he had convulsions while at work. Mental examination of this patient after his confusion had somewhat subsided, showed him to be approximately oriented in all spheres. Emotionally he was indifferent and had no insight into his condition. No delusions or hallucinations could be elicited. He performed the intelligence tests to the best of his ability. Physical examination showed a well nourished colored adult male. Pupils irregular, but equal and reacted only to light. There was a rough tremor of the extended hands, as well as of the facial muscles. Face was asymmetrical, angle of mouth deviating to the right. Deep reflexes were all diminished. Slight swaying in Romberg test. Uranalysis showed trace of albumin, hyaline casts. Wassermann reaction with blood serum was double plus, with cerebrospinal fluid was negative; cells, sixty-five per c. mm. Protein content increased. Throughout his sojourn here he complained of pain in his head, at times experienced difficulty in replying to questions. He complained of being dizzy and would be seen to throw out his hands spasmodically as if warding off something. Two months after his sojourn here he began to suffer from convulsions, which lasted for several days. He had treatment in the form of salvarsan intravenously and, several months later, the Wassermann reaction with cerebrospinal fluid became positive. However, he continued to get active treatment and his blood became negative to the Wassermann reaction, and his cerebrospinal fluid showed protein content only slightly increased, all other findings being negative. Mentally he showed marked improvement. He was oriented in all spheres and comprehended readily what was said to him, replied to all questions to the point, and was able to conduct a coherent, rational conversation. His wife was very anxious for his discharge, and we discharged him in her care as improved after a year's sojourn.

This case is an example that in some instances treatment materially helps the patient. This patient would have been going on to recovery had he stayed longer with us, but his mental picture was normal and his wife could not understand why we kept him any longer. As a result he was taken out, and about six months later he had convulsions and died.

PARESIS.

General paresis was diagnosed in twenty out of fifty-three syphilitics, or 18.86 per cent. of the total. Out of seventy-nine consecutive admissions to the female colored service eight or 10.12 per cent. suffered from paresis, about ten per cent. less than the male colored. Furthermore, cerebral lues and paresis had the same number of patients, while in the male colored paresis was nearly twice as frequent as cerebral syphilis. It is the consensus that cerebral syphilis is predominant, and we are unable to give an adequate explanation for these findings other than that the negro can go on with syphilis of the nervous system for a much longer period than the average white patient. This accounts for the rapid mortality in this disease. Out of the twenty patients, only four are living.

Involvement of the central nervous system takes place during the secondary stage of this disease, according to recent reports of various investigators who examined the cerebrospinal fluid during the early stages. They assert that in these cases where there is an involvement of the central nervous system during the secondary stage, cerebral syphilis or paresis ultimately develops. They advocate lumbar puncture, therefore, in general syphilis before the patient is discharged as cured.

The symptomatology of paresis in the negro does not vary to a great extent from that of white people The grandiose type was present in nine of the patients. In this form we often meet with the "color complex" (6) of the negro—aside from being very wealthy they are also *white*. Five were in a confused state throughout their entire residence here. Three were in an agitated and depressed state, while in the remainder euphoria alternated with depression. In the last named the symptoms usually changed after a convulsive attack.

The neurological findings were all very marked

on account of the advanced stage of this disease. Disturbance in the form of irregular or unequal pupils, or loss of reflexes was present in all cases. The tendon reflexes were lost in eight patients and diminished in four, while in six the tendon reflexes were exaggerated. In only three patients were the reflexes normal on admission.

The diagnosis of paresis with the typical laboratory findings, such as an increased protein content, pleocytosis, and a positive Wassermann in the cerebrospinal fluid, is rather an easy task. We do not always have these typical findings, however. A negative Wassermann in the cerebrospinal fluid is of frequent occurrence, and it is in the latter cases that we have to take into consideration the clinical picture of the disease. In the series reported, two had a negative Wassermann in the fluid throughout their sojourn here, but their mental picture was typical of paresis.

The prognosis in this mental disorder is unfavorable. The treated cases, it seems, share the same fate as the untreated. With the introduction of the arsenical praparations in the treatment of syphilis and the discovery of Spirochæta pallida in the brain, it was thought that a new cure for this disorder had been found. It is true that we are able to reduce the findings in the blood and cerebrospinal fluid to a negative phase, yet it is doubtful if recovery is possible. We meet with remissions in untreated cases as frequently perhaps as in treated cases. In one case we allowed the patient to go for a visit to his home for several months, and in another case—cited below—the patient stayed away from the hospital for nearly a year, and received no treatment.

Case IV. E. D. M., who was thirty-three years of age on admission. Medical certificate stated: "Unable to give the date, did not know who was President, heard a voice singing beautiful hymns, but thought he could hear them any time. Heard a voice calling him by name. Thought it was his mother's voice. Had to be fed." Status on admission, well nourished colored male, whose mental symptoms were somewhat in subsidence, but whose neurological picture showed distinct disturbances of the central nervous system. Family history showed heart disease in the family. Personal history: Well educated colored man, who earned his livelihood by pressing clothes. Gave a history of excessive alcohol and stated he had a venereal sore about five years ago. Married about ten years ago; one stillbirth from this union. Wife living. Said he had a convulsive attack in 1910, one in 1913 which he attributed to excessive indulgence in alcohol. Present illness had its onset when the patient complained of feeling "funny" and had peculiar feelings in his head. After having made several blunders that day, he finally landed in the police station on his own initiative. On entering, he said, "Here I am, are you looking for me?" While waiting for the ambulance he had a convulsion and was taken to a local hospital, where he remained for several days and manifested the mental picture described in the medical certificate. Mental examination showed him to be oriented in all spheres; had no insight into his condition. Emotionally he was somewhat elated, said he felt better than he ever did in his life. No hallucinations could be elicited. His memory was fair for recent and remote events. Intelligence tests were well performed. Physical examination showed a well nourished man; pupils irregular and unequal, reacted sluggishly to light. Face was asymmetrical. Tongue tremulous and deviated to the right on protrusion. Test phrases were slurred. Deep reflexes were markedly exaggerated. Laboratory findings: Uranalysis showed chronic nephritis. Wassermann with blood was double plus; cerebrospinal fluid—protein content increased, cells ten per c. mm.; Wassermann reaction double plus. This patient continued to improve without treatment. He appeared in court three weeks later and was discharged as not insane.

This patient has stayed from the hospital for nearly a year and as far as we can learn gets along very well. His case illustrates the remission of paresis without treatment. No doubt had we given him treatment we should have become very enthusiastic about a recovery from paresis. On the other hand, the next case illustrates how active treatment in the form of salvarsan and mercurialized serum intraspinally had no beneficial result.

Case V. J. J., who was thirty-nine years old, was admitted on a medical certificate which stated: "Patient accessible, very peculiar at times, thought he was Jack Johnson, the prize fighter, rolled up his sleeves and pants and said he was a prize fighter." Status on admission showed an excited colored adult male, whose trend of conversation was grandiose, but he showed only a few neurological disturbances. History showed patient was married, had one child living, aged ten years. Gave a history of gonorrhea and chancre. Was a moderate user of alcohol. Mental examination showed him to be euphoric and suffering from grandiose delusions. Intelligence was fair. Memory was impaired for recent events. Physical examination showed a well nourished colored man, pupils equal and regular, reacting to the usual tests. Face was asymmetrical. There was a tremor of the tongue. Inguinal and epitrochlear glands were palpable. Neurological examination showed tremor of the extended hands. Voluntary movements poorly performed. Deep and superficial reflexes were all normal. Thre was slight ptosis of the left eyelid. Slight swaying in Romberg was present. Uranalysis was negative. Wassermann reaction with blood serum was double positive; with cerebrospinal fluid, protein content increased; cells 31.5 per c. mm. Wassermann reaction double plus. This patient received mercurial injections and saturated solution of potassium iodide, also three intraspinal doses of mercurialized serum. The excitement subsided after the second injection, and the cerebrospinal fluid findings showed a reduction of protein content, cells, 14.5 per c. mm. Wassermann reaction was negative, in one in ten dilution single plus in 0.3 and double plus in 0.5. Mental picture continued to improve; he was not so grandiose, but euphoria and elation were still present. About two weeks after the third injection the patient suddenly had an attack of convulsions and died during the attack.

This case illustrates how a paretic received active treatment and died in spite of it. There is no doubt that it reduces the serological findings, but whether the patient's mental improvement coincides with the findings is questionable. The case cited seems to prove that a negative laboratory level has no effect upon the mental picture after the nerve tissues have once been affected and deterioration seems to go on. Several patients whom we treated successfully with salvarsan and mercurial injections to reduce their findings to a negative phase, are still mentally defective and continue to deteriorate.

CONCLUSIONS.

1. Our findings seem to justify the conclusion that syphilis is prevalent to a marked degree in the colored race. We are not able to state positively to what extent these findings indicate an increase of this disease in the colored race.

2. The occupations of waiter, barber, and cook, in which the negro is so widely engaged, offer many opportunities for the transmission of this disease by routes other than the sexual, and a demand on the part of the general public that employees in this field have a physician's certificate that they are free from syphilis, would undoubtedly tend to limit the spread of this disease.

3. Syphilis should be suspected in cases of nephritis where no other definite cause can be found, especially in middle aged people.

4. A negative blood Wassermann does not exclude syphilis, and suspected cases should have a provocative test. Spinal fluid examination should be made in all cases of suspected syphilis of the central nervous system. Moreover, this procedure is justified even in cases of general syphilis, especially in the secondary stage, with the hope of recognizing central nervous involvement in its earliest stages.

COROZAL, PANAMA CANAL ZONE.

THE LATE DR. CHARLES E. WOODRUFF.*

BY THOMAS E. SATTERTHWAITE, M. D., Sc. D., LL. D.,
New York.

Charles E. Woodruff, who joined this society in 1914, and died June 13, 1915, was born in Philadelphia, Pa., on October 2, 1860.

Graduating from the Naval Academy at Annapolis, in 1883, and from Jefferson Medical College, in 1886, he entered the U. S. Navy in the latter year and within twelve months the U. S. Army. On his retirement, in 1913, he held the brevet rank of Lieutenant-Colonel. Two military medals for meritorious service were awarded to him.

Colonel Woodruff will be best remembered in scientific circles as an anthropologist and as a sanitarian Prolonged service in the Philippines furnished him the opportunities for his well known work relating to the effects of a tropical climate on the white race, which was embodied in a separate volume. Out of this was subsequently evolved his *Medical Ethnology*. But *The Expansion of Races* was probably the most important of his books; it is said to have been the most valuable contribution to anthropology since Darwin's *Origin of Species*. Industriously collecting and coordinating scattered data, he brought them before his readers in a simple, intelligible, and entertaining form. Every man, whether physician or layman, who is interested in racial problems as they bear on health, wealth, and good government, should familiarize himself with Colonel Woodruff's broad survey of these topics. Other valuable material that came from his pen was contained in upward of seventy monographs on subjects bearing on military medicine, camp sanitation, and eugenics; of the latter he made a special study.

But devotion to duty was his undoing, for the enervating climate of the Philippines undermined an otherwise vigorous physique, compelling him to resign from the service at the comparatively early age of fifty-three years, after only twenty-six years of army life.

Colonel Woodruff was a broad humanitarian, endowed by nature with a keen, logical, and inquiring mind, bent on finding light where hitherto there had been darkness. Firm in his convictions, he was equally zealous in upholding them, though tolerant of the opposition that confronts new ideas. Those who differed with him were always treated with consideration, even with courtesy. It was easy, therefore, for him to win the admiration and command the respect of his coworkers. In the front rank of the scientists there is now a gap. Unfortunately, his stay in our society was so brief that few of us had the opportunity of knowing him well. His intimates have paid this tribute to him, that he was a sincere and faithful friend.

*Read at the seventeenth annual meeting of the American Therapeutic Society, Detroit, Mich., June 9, 1916. A tribute to Colonel Woodruff's memory from the JOURNAL appeared in our issue for June 19, 1915.

Contemporary Comment

Need of a National Leprosarium.—On March 25, 1916, the Senate Committee on Public Health and National Quarantine made a thorough inquiry through a hearing on Bill S. 4086, which provides for a national leprosy home. . . . Every one of the witnesses before this committee energetically portrayed the necessity for the government to take measures to prevent the spread of leprosy and to take care of those afflicted with the disease. In other words, they all thoroughly believed in governmental control. The Senate Committee on Public Health and Quarantine, according to the *Journal of the Missouri State Medical Association* for December, 1916, reported the bill favorably and it came before the Senate for unanimous passage, but was thrown into the regular calendar order by the negative vote of the Senator from Colorado. Therefore this bill will have to come before the Senate in its regular order of business. . . . Every thinking physician realizes the absolute necessity for such a home. The statistics compiled by the government on the number of cases of leprosy in this country are obviously erroneous because lepers are not reported on account of the terror the disease inspires in the community at large. Workers in this field believe there must be from 3,000 to 5,000 lepers in the United States, and have observed that the disease has markedly increased since the Spanish-American War, when leprous islands were brought into direct contact with this country through military and commercial intercourse. The writer has observed the disease in many soldiers, who contracted it during their service in the Philippines or other island possessions. These men wander about the country from place to place, homeless outcasts, whose suffering is as horrible as that of the lepers of the Middle Ages.

There are only three States in the Union that provide a home for lepers with humane laws for their control and protection. The many pitiful and dangerous cases that are carried through interstate traffic throughout the country compel us to plead with the government, not only for the protection of the public from this disease, but for the protection and humane treatment of those afflicted with it. This can be accomplished only by the passage of such a bill as is now pending before the Senate; namely, Bill S. 4086.

THE OPEN TREATMENT OF INFECTED WOUNDS.

The open and open air treatment of infected wounds are practically synonymous terms, signifying that infected wounds are not bandaged but left open to the air, light, and sun. Moreover, the treatment of such wounds in war and of those occurring in civil life is, from a broad point of view, the same, although special circumstances may alter the viewpoint.

This form of treatment was advocated some months ago by Dyas, of Chicago, who advised that infected wounds should not be covered but only protected by a cradle or screen of netting. Crile (*Surgery, Gynecology, and Obstetrics*, October, 1916), of Cleveland, draws attention to the omission of dressings in the treatment of infected wounds, together with the employment of electric light as a substitute for the light and heat of the sun, in conjunction with the use of hypochlorous acid solution, as demonstrated by the Frenchman, Chaput, and practised by Dubouchet and others, with, it is stated, remarkable success. Crile himself introduced this mode of treatment into the Lakeside Hospital, Cleveland, and concludes as follows with regard to the results: Wounds heal best when infection is hindered or destroyed by the agent least harmful to the tissue and without the irritation of foreign bodies in the form of dressings. All these ends are served by the use of hypochlorous acid solution and by exposing the undressed wound to constant light and warmth. Some British surgeons and more French surgeons appear to have convinced themselves that the open air treatment, whenever the conditions are favorable, is eminently rational. Moynihan went so far as to state that the average dressing of a suppurating wound is, in effect, a pus poultice, and this view is approved by Crile and a large number of surgeons who have gained clinical experience in the stern school of war surgery. Some surgeons indeed strongly condemn all impermeable dressings under any circumstances; among them is Primrose, who, while acting as surgeon to a hospital in Saloniki, came to the conclusion that the bandaging or close covering of infected wounds was a pernicious procedure. The sound principles underlying the open treatment of wounds have been amply demonstrated by military surgeons in the United States, who treated gunshot wounds on the prairies and great plains of virgin soil, with the minimum of infection, and these results were corroborated by British surgeons in South Africa. The conditions existing in northern France and Belgium, however, are widely different from those of the plains of western America or the veldt of South Africa, and therefore the general success of the treatment at the French front affords testimony to its effectiveness of an extremely valuable nature.

For infection to establish itself, an invading germ must find lodgment in a susceptible subject and furthermore must be in a position to maintain itself and multiply in its new situation. It has been pointed out in the editorial pages of this JOURNAL on several occasions that not only is the soil of Northern France and Belgium permeated with anaerobic spores, but that all the conditions of trench life tend to favor infection. The soldier is, as a rule, weakened physically and mentally by the life of the dugouts and by the stress and strain of modern warfare, and his clothes become saturated with the soil. No wonder then that anaerobic infection is rampant among the soldiers on the French front. The treatment seems to be to drain freely and irrigate as continuously as possible with a suitable antiseptic or with saline solutions. Unfortunately, so far no suitable antiseptic has been forthcoming; many antiseptics have been called but few chosen, while Wright and his disciples contend that all are equally useless. The French surgeons, from the

first, have employed solutions of hydrogen peroxide, and although Dakin's solution and solution of magnesium hypochlorite have now a great vogue, hydrogen peroxide is still considerably used, by itself and in conjunction with these solutions. In the treatment of anaerobic infection, it seems to be especially indicated, as by giving off nascent oxygen it supplies the very lack that permits these spores to flourish, and thereby checks their further development. Infected wound treatment appears to have resolved itself into open air treatment when possible for both superficial and deep lacerated wounds, with the aid of the electric light and the antiseptic best fitted for the occasion.

THE TREATMENT OF CEREBROSPINAL MENINGITIS.

In this country the reports have been in quite general agreement that the early intraspinal injection of Flexner's serum is of great value in shortening the course of cerebrospinal meningitis and in materially reducing the mortality. Thus as recently as 1913 Flexner reported a mortality of only thirty per cent. in a large series of cases so treated, which was a great reduction from the usual mortality of about eighty per cent. Abroad, however, opinion as to the value of this serum has been far less favorable, and many have given up its use on account of failure to obtain good results.

Owing to this failure, European workers have tried other methods of treatment, but opinion as to their values is still divided. Prompted by this state of affairs, C. Worster-Drought (*British Medical Journal*, November 18, 1916) records his own experiences of a combined plan of treatment. He believes that serum is of value early in the course of the infection and that its value decreases with each day of delay. He advocates the immediate administration of a dose of thirty mils intraspinally in every case upon suspicion of its being of meningococcal origin. This dose should then be repeated daily for not less than four days, and longer if the spinal fluid continues to be very turbid. He uses the polyvalent serum prepared by the Lister Institute. If less than thirty-five mils of spinal fluid can be withdrawn at a puncture, the amount of serum injected must be reduced and should always be kept at a point five mils less than the total amount of cerebrospinal fluid withdrawn. The injection should be made by gravity and its flow aided by long and deep inspirations with short and quick expirations on the part of the patient. After the serum has been given for four or more doses the practice of daily lumbar puncture should be continued until the spinal fluid obtained is nearly normal.

Beginning at the same time as the administration of the serum, a vaccine should be employed. The first dose will probably have to be of a stock polyvalent vaccine, but thereafter an autogenous one should be used. The initial dose should be 250 million organisms; the second 500 million, and each succeeding dose should be increased by a like number of organisms until the maximum of 2,500 million is reached. If a rise of temperature of two degrees F., or over, occurs, the next injection should be of the same size. The intervals between injections should be of four days. It will not always be necessary to give the last two doses of the schedule, as improvement may be such as to render further treatment unnecessary.

To this combined plan of treatment the author would add the use of symptomatic remedies such as 1.3 gram of sulphonal for sleeplessness, dilute hydrocyanic acid for nausea and vomiting, and morphine for excitement. By these means he has been able to reduce the mortality in his series of cases to about thirty per cent., which is far lower than that recorded by European observers under any other plan, including the use of serum. The beneficial effects of the vaccine were most pronounced in cases which tended toward a more or less prolonged course. No ill effects were observed from such large doses of vaccine, which far exceeded those recommended in this disease by enthusiasts about this agent.

EUGENICS AND RACIAL DEGENERATION.

The well known fact that inbreeding has a tendency to accentuate desirable as well as evil qualities and thus disturb the normal balance of the progeny, is nowhere so well exemplified as among races that practise strict intermarriage. Strength and weakness, genius and idiocy, endurance and low resistance go hand in hand, depending on the mating of persons with certain propensities and hereditary proclivities. Royal families often exhibit tendencies to neuroses and degeneracy, owing to close intermarriage. Among races, the Jews furnish numerous examples of the evil effects of intermarriage, compensated to a certain extent by the intensified mental development shown by many of that race.

It is certain that diabetes and disturbances of the nervous system, from neurosis to insanity inclusive, are more common among the Jews than among other European races. A rather uncommon nervous affection—progressive amaurotic idiocy, which affects children and occurs as a rule in families—is found almost exclusively among Jews. Falkenheim collected sixty-four cases and of these thirty-seven occurred in thirteen families, from two to five cases in each. In eighty per cent. the disease occurred

among Jewish children. Indeed, the first observations were made by Tay and Sachs among the Jewish immigrants from Russia. In Russia twenty-nine cases, all in Jews, were observed by various authors. I. A. Schabad (*Roussky Vratch*, August 13, 1916) observed two cases of this affection in Jewish families residing in Petrograd. In one case a little one year old girl contracted the disease when six months old. In the other, the child, a boy, acquired the disease when nine months old and died a few months later. The author suggests that the reason more cases have not been observed in Russia is because the physicians are not familiar with it, and it is frequently overlooked.

While in the cases reported by the author there was no history of consanguinity, such a relationship was noted by Kovarsky in fifty per cent. of his cases. The very fact that the disease is due to degenerative changes in the central nervous system, and that it has been observed principally among Jews, makes it more than likely that this is another penalty this race pays for its time honored custom of intermarriage.

DIFFICULTIES IN QUARANTINE.

Of the many problems that the public health officer encounters none is harder to solve than that of quarantine. In the larger cities, where there is a well established health board and an efficient police force, the matter can be handled in a fairly satisfactory manner. In the smaller communities, however, there are many difficulties, not the least being the indifference or even open hostility of many to the existing laws. They either can not or will not see the necessity of enforcement.

It is an axiom that childhood is the period of infectious diseases, and unless the infected child can be controlled the disease will spread. As practically all children go to school the point of attack should be the school, but if there is no medical inspection, or an inadequate one, the small flame may become a conflagration. At the present moment, in a community of thirty-five thousand, inspection is inadequate, the teachers are overworked, and there is an epidemic of mild scarlet fever. The cases are so slight that the condition could be easily overlooked by the lay observer, and if the nurse does not happen to get to that particular school early in the day, many other children have been exposed.

To many a mother, rich or poor, the school is a blessed place to which the children may be sent so as to allow rest at home. The consequence is that many a child who should be at home, probably in bed, is sent to school, exposing others to the same disease. The chief idea is personal convenience, duty to the neighbor not being thought of. Another element of difficulty is the desire on the part of the child, usually fostered by the parent, to have an unbroken record of attendance. This is especially the case in Sunday school, where prizes for attendance are given.

There are times when the parent sends in as an excuse for absence that the child has chickenpox, when it may be smallpox, or tonsillitis, or even diphtheria, and does not call in a doctor. Everything is done to avoid having the house placarded and quarantine established. If the city is one in which there is a corps of visiting physicians or nurses who can attend immediately, no harm may result, but frequently this is not possible and the child remains a menace.

It is obvious that there should be no opposition to the energies that are being directed against tuberculosis and typhoid fever, but there is not enough education of the public concerning the commoner infectious diseases of childhood. Physicians, as a rule, are apt to forget that their knowledge of danger of apparently mild infections is not shared by the public at large. The parents should be shown, not only that their children are dangerous to others, but that the reverse is true. Unless each father and mother appreciates the fact that all must do their part and do it quickly, the problems of quarantine will remain as difficult as ever. The only way to solve them is to get the necessary cooperation through constant reiteration of the facts to the parents, and to the children as well.

CONCURRENT MEASLES AND CHICKENPOX.

Dr. A. J. Rice-Oxley, of London, communicates to the *British Medical Journal* for November 25th, what was a unique experience in his practice—which has extended over two decades. His patients were two boys and two girls. Jim began, he writes, with an attack of measles, February 1st. John acquired chickenpox February 6th and measles February 10th, both rash and spots being well out together. Peggy began with measles February 18th and had chickenpox March 3rd. Ermin had chickenpox and measles February 25th, practically simultaneously. John, Peggy, and Ermin were very distinctly ill. John had been exposed at school to chickenpox and Jim to measles.

News Items

Assistant Physician Wanted at Onondaga Sanatorium.—The Civil Service Commission of the State of New York announces that an examination will be held on January 27th for the position of assistant physician in the Onondaga County Tuberculosis Sanatorium; salary, $1,000 with maintenance. This examination is open to men only who are at least twenty-one years of age and are licensed to practise medicine in the State of New York. Applications should be filed with the Civil Service Commission not later than January 17th.

Cook County Hospital.—According to a report issued by the warden of the hospital, 81,102 cases were treated at the hospital during the year ending December 1st. Two new wings to the administration building are being constructed, and when these are finished the total capacity of the hospital will be 2,700; in an emergency the institution will be able to handle between four and five thousand patients. The immediate erection of a new laboratory and morgue is recommended in the report.

Personal.—Dr. Irving David Steinhardt, of New York, announces that he will deliver a series of educational lectures for women and girls, entitled Ten Sex Talks to Girls, at the Free Synagogue, 36 West Sixty-eighth Street, New York, beginning on Monday evening, January 8th, at 8:30 o'clock, and continuing on consecutive Monday evenings thereafter until the course is completed.

Dr. J. Madison Taylor, of Philadelphia, addressed the College of Physicians, of Pittsburgh, on the evening of Thursday, December 14th, on the subject of the Scope of Reconstructive Therapeutics.

Free Medical Lectures at Harvard.—The faculty of medicine of Harvard University announces the usual course of free public lectures to be given at the Medical School on Sunday afternoons during the months of January, February, March, and April. The program for January is as follows: January 7th, Alcohol and Efficiency, by the Rev. Dr. Francis G. Peabody; January 14th, The Care of the Wounded with the British Expeditionary Force in France, by Dr. Hugh Cabot; January 21st, Infantile Paralysis, Precautions Necessary and Unnecessary, by Dr. E. W. Taylor; January 28th, Shock in the Trenches, by Dr. W. T. Porter.

The Teeth of School Children.—Out of 330,179 school children examined in 1914 in the city of New York, 194,207, or 58.8 per cent., suffered from defective teeth. This exceeded the sum total of all the other defects noted by nearly 80,000. Defective teeth impair general health and impede school progress. Disorders of the digestive tract, tuberculosis, and various other diseases frequently are preceded by diseased conditions in the mouth. There is a direct relationship between dental development and mental development, and it is absolutely essential to good work in schools that children's teeth be maintained in a healthy condition. The United States Public Health Service recommends that a good tooth brush be included in the list of Christmas presents for every American child and that its use be made a part of the daily training.

Chemists Wanted by the Health Department.—The Municipal Civil Service Commission announces two examinations to secure a list of eligible persons to fill vacancies in the Bureau of Food and Drug Inspection of the Department of Health of the City of New York. One of the positions is that of pharmaceutical chemist, and applications will be received up to January 17th; for the other position, that of microanalytical chemist; applications will be received up to January 18th. The duties of the former position will consist of the examination of patent and proprietary medicines, the examination of crude drugs and official pharmaceuticals, and the representation of the Department of Health in the courts as an expert. The duties of the latter position will consist of microscopical examination of foods and drugs, chemical tests on microscopic slides, chemical analysis, and the representation of the department in court. Candidates for the position of pharmaceutical chemist must be graduates of a technical school, of recognized standing, with chemistry as the major subject, and in addition have had three years' experience in pharmaceutical chemistry after graduation, or proof of training and experience recognized by the Municipal Civil Service Commission as equivalent. The compensation rates proposed by the Board of Estimate and Apportionment for both positions are from $2,280 to $3,660 per annum. The existing vacancies are both $2,280. Both examinations are open to all citizens with the required qualifications. For further particulars apply to the Municipal Civil Service Commission, Municipal Building, Room 1400, New York City.

Lectures on Psychopathology.—Announcement is made of a course of six lectures on psychopathology, to be given by Dr. E. E. Southard, professor of neuropathology in the Harvard Medical School and director of the Psychopathic Hospital, Boston, in Schermerhorn Hall, Columbia University. The lectures are as follows: Tuesday, January 2d, Neuropathology and Psychopathology; Wednesday, January 3d, The Brains of the Feebleminded; Wednesday, January 31st, Frontal Lobe Functions; Thursday, February 1st, Analysis of Delusions; Thursday, February 8th, The Unconscious: Friday, February 9th, Psychopathia. The lectures will be illustrated as far as practicable with lantern slides.

Examination for Assistant Epidemiologist in the Public Health Service.—The United States Civil Service Commission announces an examination, open to men only, for assistant epidemiologists in the United States Public Health Service, at salaries ranging from $2,000 to $2,500 a year. The duties of the position include the making of epidemiological and sanitary surveys to determine the prevalence and causation of disease, to conduct laboratory studies in relation thereto, and to recommend measures to prevent and control outbreaks of disease. It is desired to secure persons thoroughly competent in the various branches of sanitary bacteriology, and especially in isolating the typhoid bacillus from infected persons and materials. Graduation from a medical school of recognized standing, and at least three years' experience in epidemiological work under federal, State, or local authorities, and experience in laboratory technic, are prerequisites for consideration for this position. For full particulars regarding the scope of the examination address the United States Civil Service Commission, Washington, D. C. Applications must be filed with the commission at Washington prior to the hour of closing business, January 30, 1917.

The "Safety First" Campaign.—That this campaign, inaugurated a few years ago, has been successful is shown by the figures concerning accidental deaths contained in the summary of mortality statistics for 1915 issued by the Bureau of the Census. For 1913, 54,011 deaths were reported as due to accident; for 1914 the corresponding number was reduced to 51,770, and for 1915 to 51,406; and during this period there was not only an increase in the population of the registration area as it existed in 1913, but an increase in the extent of the area itself. The rate per 100,000 population for accidental deaths fell from 85.3 in 1913 to 78.5 in 1914 and to 76.3 in 1915. There has been a very considerable reduction in fatalities due to railway, street car, mine, and machinery accidents, and the increase in those resulting from automobile accidents has not been as rapid as the increase in the number of machines in use. Deaths due to railway accidents and injuries totaled 6,652 in the registration area in 1915, or 9.9 per 100,000. This number includes fatalities resulting from collisions between railway trains and vehicles at grade crossings. This death rate is the lowest on record and shows a marked decline during the past ten years. Deaths resulting from street car accidents and injuries numbered 1,555, or 2.3 per 100,000. This rate, like that for railway fatalities, is the lowest on record and shows a material falling off during the past ten years. Automobile accidents and injuries caused 3,978 deaths in 1915, or 5.9 per 100,000. There has been an increase in this rate from year to year, but, as already mentioned, the increase has not been so rapid as that in the number of machines in use. The number of deaths from mine accidents and injuries in the registration area in 1915 was 2,009, corresponding to a rate of 3 per 100,000. This rate shows a material decline as compared with the corresponding figure for 1913, 3.6, and a very great decline as compared with that for 1907, 4.8, which is the highest on record. Deaths caused by machinery accidents in 1915 numbered 1,257, or 1.9 per 100,000. This rate also shows a marked decline during recent years, the corresponding figures for 1913 and 1914 being 2.4 and 2, respectively. The highest recorded rate from this cause is 2.5, for 1907.

Modern Treatment and Preventive Medicine

A Compendium of Therapeutics and Prophylaxis, Original and Adapted

THE THERAPEUTICS OF A PHARMACOLOGIST.

By A. D. Bush, M. D.,
Professor of Pharmacology and Therapeutics, University of Southern California.

Fiftieth Communication.

PHARMACODYNAMICS.

As one reads through the sections on treatment in the various textbooks on internal medicine, or scans the columns on therapeutics in some medical journals, he will ofttimes wonder what can possibly be the pharmacological basis for the sundry drugs recommended; and he will have much curiosity concerning the logic whereby the authors arrive at their therapeutic conclusions. An examination of this logic will reveal all too frequently the hoary fallacy of *post hoc ergo propter hoc*. How many medical writers, and how many practitioners as well, are able to reduce their reasonings concerning treatment to the syllogistic form? Yet how necessary it is in all branches of medicine to attain as high a degree as possible of logical accuracy. What rational justification can Doctor Brown have for using acetphenetidin for toothache because Doctor Smith reports symptomatic alleviation of hemicrania after administering this drug? Yet how much general therapy has no more adequate logic underlying it. The mental processes of Doctor Brown in this instance may be analyzed somewhat as follows: Toothache is painful; acetphenetidin has a general reputation for its analgesic properties; therefore, acetphenetidin is indicated for the relief of this aching molar. The main fallacy here lies in the limitations of the minor premise, whereby the conclusion is vitiated; but the reasoning as a whole involves several possibilities of error. No account is taken of the underlying cause of the ache, or of the path of sensory transmission, or of the possibility of this path being blocked by acetphenetidin. Furthermore, granting that all these points were so conclusively determined as to warrant this coaltar derivative being used, there yet remains the important question whether or not acetphenetidin possesses any adverse potentiality such as might normally cause one to hesitate about preferring this particular drug to some other less dangerous.

The loose reasoning which sorely afflicts therapeutic discussions today arises from several causes, but the three following are among the chief: (1), The excessively overburdened materia medica, the pharmacodynamics of which are known conclusively in but a small percentage of cases; (2), the gullibility of the average practitioner in the reading of quasiscientific literature; (3), intellectual indisposition.

Concerning the first point, consider for example the new Pharmacopœia—how markedly its bulk would be decreased, with inverse effect on its usefulness, if the inert, the worthless, and the superfluous preparations were omitted. Teachers of pharmacology are urged to make use of the Pharmacopœia as a text in their classrooms, but they are largely debarred from so doing by the unpharmacologic nature of the book. What both teachers and practitioners really need is a treatise embodying the conclusions and recommendations of a convention where the guiding spirit would be pharmacologic efficiency instead of pharmaceutic expediency. Such a convention, through its analytic deductions, could furnish scientific medicine with an official guide possessing both the pharmacal definiteness of the present Pharmacopœia and a pharmacodynamic demonstrableness now nearly lacking. Fewer drugs, but with accurate and thorough information concerning those few, is the first need in establishing rational therapeutics.

The only way to cure and prevent general gullibility is to develop the habit of critical analysis; therefore, both personal habits and educational methods that tend contrariwise should be promptly corrected.

Intellectual slothfulness is a question both of temperament and of training. We hope to so elevate and standardize our educational requirements ultimately as to automatically exclude the mentally unfit from the profession of medicine; with less optimism, we hope to so clarify our curricula and our pedagogical methods as to furnish students with assimilable pabula, instead of, as at present, cramming down them a heterogeneous, incoordinated mass of unvaluated data—not a little of which has wheat to its chaff e'en as Bassanio's reasons.

Arthritis deformans.—George F. Butler (*Chicago Medical Recorder*, November, 1916) states that the treatment of this condition should be begun as soon as any definite signs of the disease have become manifest, and it must be so conducted as to retain and increase the patient's strength. It must be treated persistently for many months for lasting effects. The diet is a matter of first importance, but it should not be limited except in being restricted to articles of food which the patient can best digest and assimilate; meat and vegetables should be given freely. The diet should be generous, with the aim of increasing the patient's strength. Gastric acid fermentation is common, and should be combated by restriction of sweet and farinaceous foods, the use of red meat for a few days, and later by milk with sodium bicarbonate, chalk or lime water, junket, and cream. Then green vegetables and farinaceous foods may be added, with the exception of oatmeal. At least thirty mils of olive or codliver oil should be given each night and bacon gravy, fat bacon, cream, butter, and margarine are also valuable. Beef and mutton fats should be avoided. Salt should be used liberally. Acids and acid fruits should not be taken. Glucose and honey are preferable to cane sugar. Grapes, bananas, nuts, and stewed fruits may be given during recovery. Water, especially hot water, is the best beverage. Tea, coffee, or cocoa may be used if cooked for at least fif-

teen minutes with milk. Milk and soda water (two grams of sodium bicarbonate to the litre) may be used. Sudden atmospheric changes should be avoided, and it is well to send the patient to some warm, equable climate if he can afford it. Thermal baths and baths of peat or mud are helpful in moderation, and vapor baths are often of marked temporary value. Among drugs, guaiacol carbonate, arsenic, iron, and potassium iodide are the most valuable. General tonic treatment is indicated. Acid fermentation should be corrected by the use of a mixture of the following composition:

℞ Sodium bicarbonate,.....2.0;
Potassium bicarbonate, ...0.6;
Aromatic chalk, ...1.0.

This should be given in a glass of milk half an hour before each meal, and twice the amount at bedtime. Calcium chloride, hydrochloric acid, or minute doses of the tincture of ferric chloride may be given after meals as stomachics. Little can be expected from local treatment and the use of stock vaccines does not offer much help. Autogenous vaccines, however, are of value where a focus of infection can be demonstrated, but care must be taken not to cause a marked reaction from their injection.

Paraspecific Serum Therapy by Mouth in Eye Infections.—L. Frozier (*American Journal of Ophthalmology,* October, 1916) calls attention to the fact that in an acute eye infection it is most important to stop the progress of the disease before it has caused irreparable damage, and that it often is difficult to quickly recognize the exact nature of the infection and precious time is lost in bacteriological researches, which often are quite complex. In awaiting the results of such researches it is well if we can strengthen the patient's natural defenses by some help taken from another organism. At the beginning of the infection, when no deep intoxication has yet developed, little will suffice to awake the vital resistance of all the tissues. This can be secured by having the patient take some antimicrobic serum by mouth. Antidiphtheritic serum is the easiest to obtain, and this is given by the following prescription:

℞ Antidiphtheritic serum, ... 10 grams;
Raspberry syrup, ... 30 grams;
Water .....100 grams.

Misce. Sig.: A tablespoonful to be taken every hour for the first three days; then every two hours for at least a week.

The method of employment by mouth is so simple and agreeable to the patient that it can be prescribed even before there is any indication for an injection, and the dose can be doubled if necessary without inconvenience. It also permits the simultaneous application of all local medication, which must never be neglected. Frozier says that the effects will not fail to show themselves. The organism will react energetically, often the infectious process is stopped, the patient reports a reduction, even the disappearance of pain, and an increase of strength, appetite, and sleep. If a cure is not established the specific serum or vaccine can be employed with accuracy, since by that time the bacteriological examination will have been able to furnish a precise diagnosis. The administration by mouth avoids all danger of serum affections.

Control of Nausea and Vomiting of Pregnancy.—John Cooke Hirst (*Journal A. M. A.*, December 16, 1916) asserts that on the theory that during normal sexual life corpus luteum is being constantly absorbed, while during the first three months of pregnancy such absorption is in abeyance, it was thought possible that this absorption had some influence on the occurrence of nausea and vomiting. The administration of luteum extract was tried in a series of thirty-six unselected cases with control of the symptoms in thirty-two. Doses up to one mil each were given once or twice daily, as many as forty-two injections having been given in one case. Most cases were controlled by about six doses of one mil each, injected every other day. The injections were given intramuscularly and massaged for a few minutes to minimize the pain they caused. No ill effects were observed.

Some Indications for Splenectomy.—William J. Mayo (*Lancet,* November 25, 1916) states that although comparatively little is known regarding the functions of the spleen and its precise role in certain diseases, in which it is evidently involved, we have gained considerable empirical knowledge regarding the effects of its removal. It has been abundantly shown that the presence of the spleen is not essential to life and that its loss is not followed by ill effects. There are, further, certain conditions in which its surgical removal is followed by improvement in the patient's health or even complete cure. Thus splenectomy is curative in selected cases of splenic anemia, hemolytic jaundice and allied disorders, and in certain ill understood conditions simulating pernicious anemia, leukemia, and hepatic cirrhosis. It is also a valuable procedure in certain parasitic splenic enlargements—especially syphilis and malaria—and as a palliative measure in some cases of pernicious anemia. Splenectomy has also found application in portal and biliary cirrhosis with splenic enlargement.

Vaccine Therapy in Septic Gunshot Wounds.—R. H. Jocelyn Swan (*Lancet,* November 18, 1916) reports that in nearly all gunshot wounds there is a multiple infection, but the most constant organisms present are a bacillus of the proteus or colon group, pyogenic cocci of the common types, and one of the anaerobic gas forming organisms. On the strength of recent work done by Goadby a mixed vaccine of proteus and streptococci has been used by him in all septic military wounds with the most gratifying results. His present routine is to give a dose of this mixed vaccine in each case without waiting for a bacteriological examination of the tissues. At the same time the wound is freely opened and drained and its bacteriology determined. This latter forms the basis for the future use of vaccines. Those cases operated in without a preliminary dose of this vaccine provided the instances of high postoperative fever, while this occurrence was usually absent in similar cases which had received the vaccine twenty-four to forty-eight hours before operation. The greatest value of the use of the vaccines was found in cases of septic fractures of the long bones, and those which entered joint cavities. Aided by the effects of the appropriate vaccine, it was possible to plate such fractures, or to excise the infected joints with the best of results.

Treatment of Fracture of the Spine.—Norman Sharpe (*American Journal of the Medical Sciences*, December, 1916) believes that in every case of fracture of the spine with damage to the cord, excepting only complete obliteration of the bony canal, an early laminectomy is urgently indicated to relieve the cord from the damaging effects of bone pressure, hemorrhage, and edema, and to give the nerve tissue the best possible chance for repair. This operation is not dangerous or difficult in skilled hands, and when it is done early it not only relieves pressure, but it provides drainage for the edema and whatever hemorrhage is present, while at the same time it allows more space for the cord if there is fracture dislocation, and relieves the pressure effects of angulation.

Methods of Raising a Low Arterial Pressure.—W. M. Bayliss (*Brit. Med. Jour.*, November 25, 1916) states that the injection of saline solution intravenously will restore the blood pressure only to a limited extent when low from hemorrhage. If, however, the vicosity of the saline solution employed be increased by the addition of gelatine or a gum the pressure can be restored to normal and the effects of the injection will be quite lasting. This is due to the prevention of the loss of water through the kidneys or into the tissues by the osmotic powers of the colloid. In the fall of blood pressure due to shock with peripheral vasodilatation the addition of barium chloride to the colloid saline solution is most satisfactory. The barium chloride should be used in the proportion of one milligram per kilogram of the patient's body weight.

Shock at the Front.—W. T. Porter (*Boston Medical and Surgical Journal*, December 14, 1916), who was sent to the front by the Rockefeller Institute to study traumatic shock in freshly wounded soldiers in search for a means of prevention or cure, reports after recording his observations that the treatment of shock requires: 1. A special position of the wounded; the abdominal vessels higher than the heart and the brain; 2, heat; 3, intravenous injections of normal saline solution; 5, transfusion of blood, in certain cases; 6, the taking of the diastolic pressure every half hour.

The patient should be placed on a special bed, the central part of which is identical with a surgical operating table, the foot raised thirty cm., with a pillow not more than six cm. high. The bed is heated electrically from below. A stand 1.5 meters above the patient supports a bottle of normal saline solution, kept at 39° C. by an electric heater. The heat should be continued until the feet and hands of the patient are warm, and then turned off, at least for a time. When the diastolic pressure is below eighty mm. Hg., normal saline solution should be injected into a vein. It must be at 38° C. when it enters; about 500 c.c. may be injected, but it is not desirable to continue the injection after the diastolic pressure has reached eighty mm. Hg. The injection should be made slowly, lasting about ten minutes. If the pressure falls some time after the first injection a second should be given. If the pressure falls again below eighty mm. a mixture of 0.5 c. c. of a 1 in 1,000 solution of adrenaline in fifty c. c. of normal saline solution should be injected very slowly into another vein, to be suspended at once if the heart becomes irregular. The systolic pressure is a less reliable guide than the diastolic, because it is relatively more affected when the heart beat in low blood pressures becomes frequent and feeble. It is especially upon the diastolic pressure that the nutrition of the nerve cells depends. In every serious wound it is most important that the diastolic pressure be recorded at the earliest possible moment, for the longer a low arterial pressure exists the more difficult is the recovery; yet desperate cases may be saved.

Impregnation of Clothing.—R. J. Willan (*Lancet*, November 25, 1916) states that the frequency with which fragments of clothing are found embedded in military wounds, their production of infection and sepsis, and the difficulty encountered in the efforts to locate such fragments suggest the desirability of the impregnation of soldiers' clothing with some substance or mixture which would be antiseptic and opaque to x rays. Preliminary experiments led to the adoption of the following solution for such impregnation:

Boric acid	15 parts;
Salicylic acid	15 parts;
Sodium borate	25 parts;
Water	500 parts.

Such a mixture is sufficiently antiseptic greatly to inhibit bacterial growth, gives a good x ray shadow and is not irritant to the skin or deeper tissues. Its effectiveness in actual military use has not yet been tested.

Reactions Following the Intravenous Injection of Salvarsan and Neosalvarsan.—B. Barker Beeson (*Medical Review of Reviews*, December, 1916) writes particularly of the reaction termed by Milian nitroid crisis, which is characterized by a flushing of the face, especially of the cheeks and ears, by increased rapidity of the pulse, and by dypsnœa. Severe pain in the chest may be present, especially over the precordium, and syncope occurs in extreme cases. The condition is very similar to that produced by the inhalation of amyl nitrite. These crises usually occur during an injection, but sometimes do not appear until later, even on the second or third day, when they are called secondary nitroid crises. The best vasoconstrictor to use in such a case is a one to 1,000 solution of adrenalin chloride, the minimum dose of which should be one ccm., equal to one milligram of drug. As much as four milligrams have been given in divided doses, but usually one half or even one fourth of this amount will suffice. In cases of coma two to four milligrams may be given within one or two hours. The best method of administration is to inject the solution deeply into the muscles of the gluteal region. When given subcutaneously its effect is more transitory, while the intravenous route should be reserved for urgent cases, such as those of serous apoplexy. Flushing of the face during an injection of salvarsan or neosalvarsan should be an indication for stopping the procedure at once, and the giving of one milligram of adrenalin. When the patient comes for another injection give one or two milligrams beforehand, and there will be no reaction, or a very mild one, in the majority of cases.

Paroxysmal Auricular Tachycardia.—H. Straub (*Münchener medizinische Wochenschrift,* September 26, 1916) reports a case in which during the attacks the duration of the ventricle electrocardiogram (R-T) was less than two thirds. This is not in accord with the generally accepted view as to the formation of the T curve, but seems to support the opinion that the electrogram of the muscular elements of the heart consists of two principal groups, the R group and the T group.

Herpes Zoster after Vaccine Treatment.—Horace Greeley (*Journal A. M. A.,* December 2, 1916) reports that an autogenous streptococcus vaccine was given in doses of 200 millions to a child eight years old for chorea, and after the second dose there developed a typical herpes zoster, which ran the usual course. The zoster was thought to be due to a focal reaction in the region of the affected nerves due to the probable location in their vicinity of the streptococci which were causing the chorea.

Vaccine Therapy in Gonorrhea.—A. Ravogli (*Ohio State Journal of Medicine,* December, 1916) concludes that: 1. Vaccine therapy for gonorrheal affections has a value—not absolute, but relative, to its localization and complications. 2. Vaccination alone is not capable to extinguish the process in the urethra, but it may shorten the process if combined with local antigonorrheal measures. Antigonococcic vaccination seems more active in secondary gonorrheal localizations. 3. The injections given under the skin or in the muscular masses cause no inconvenience, and the reaction is generally accompanied by fever. 4. The biological reaction and the symptoms following the vaccination have no other diagnostic value as they are not constantly in accordance with the clinical symptoms.

Disinfection of Meningococcus Carriers.—M. H. Gordon and Martin Flack (*British Medical Journal,* November 18, 1916) state that the great difficulty of ridding the nasopharyngeal regions of the meningococcus in persons who have become carriers, either after infection or from contact, is well known. The ordinary methods of applying antiseptics have not given very promising results, probably owing to the failure of these to reach all of the infected recesses. The authors have conducted a series of investigations, using medicated steam nebulæ, and have secured very satisfactory results in most cases. They employed chloramine or zinc sulphate, the former having proved much the more effective. One to two per cent. solutions of the former were used and one litre of the solution was liberated in a period of twenty minutes into a room of 750 cubic feet capacity. The patient remained in this atmosphere for a like period of time and practised deep inhalations through the nose. In a series of chronic carriers sterilization was secured after four to thirteen daily exposures. Three similar cases were not cured by fourteen to sixteen exposures. Lightly infected carriers responded about as well to nebulæ containing zinc sulphate as they did to those of chloramine, but zinc was far less efficient in the heavily infected cases. Owing to the climatic conditions during the summer the zinc sulphate, however, proved preferable, as the chloramine became irritating when the wet bulb temperature of the chamber rose too high.

Artificial Pneumothorax in the Treatment of Pulmonary Tuberculosis.—W. C. Farmer (*Texas State Journal of Medicine,* December, 1916) concludes that artificial pneumothorax is a safe procedure when carefully and properly performed according to the best technic. In certain cases of pulmonary tuberculosis not benefited by the usual methods of treatment arrestment may occur by the continuous use of artificial pneumothorax. Artificial pneumothorax is entitled to definite recognition in the treatment of pulmonary tuberculosis, but should be undertaken in cases before they have reached a hopeless stage.

The Bacteriology of the Feces in Diarrhea of Infants.—W. R. Logan (*Lancet,* November 11, 1916) states that painstaking bacteriological examinations of the flora of the stools of normal breast fed infants, of normal artificially fed, and of diarrheal infants showed the following results: The flora of normal artificially fed infants differed from that of the normal breast fed mainly in a decrease in the acid tolerant organisms, an increase in the colon group, and in the appearance of members of the group which does not ferment lactose. The flora of infants with diarrhea showed similar changes, which, however, were more marked. All of the infants with diarrhea were artificially fed. Dysentery bacilli were isolated from the stools of three of the diarrhea cases.

Treatment of Acute Alcoholic Delirium.—James J. Hogan (*Journal A. M. A.,* December 16, 1916) gives on the basis of his observation that patients with acute alcoholic delirium were suffering from an acidosis, a form of treatment adopted to control this manifestation along with the control of the delirium. It consists in the intravenous injection of the following solutions, mixed with 850 mils of freshly distilled water or of filtered, boiled tap water:

No. 1. Sodium chloride (chemically pure).... 5.8 gm;
Sodium bicarbonate (chemically pure). 8.4 gm;
Distilled water .....120.0.
Boil and filter. Reboil before using.
No. 2. Sodium bromide (chemically pure).... 10.2 gm;
Distilled water 30.0
Treat as above.

The total solution, amounting to 1,250 mils, was heated to 110° F. and given intravenously over a period of about half an hour. In addition to this solution, glucose was also given intravenously, prepared as follows:

Glucose (commercial) ..... 80.0 gm;
Water (distilled) .....250.0.
Boil; add 0.25 gram of blood charcoal and let stand for twenty-four hours; filter and reboil.

These intravenous injections were repeated as often as every two hours in very severe cases until the patient was sleeping soundly. The effects of the injections were to neutralize the acidosis, promote the elimination of acids and toxic substances, provide a nerve sedative, and afford some fuel for the tissues. After the initial delirium had been controlled the treatment consisted in active elimination by means of a dose of 0.3 gram of calomel followed by 30.0 grams of magnesium sulphate. The mortality in a series of sixty-four cases treated in this way was 9.3 per cent., and the average stay in the hospital was less than three days.

Miscellany from Home and Foreign Journals

Extragenital Chancres.—H. N. Cole (*Journal A. M. A.*, December 16, 1916) reviews the literature of this condition—that is primarily syphilitic lesion occurring elsewhere than on the genitals—and adds sixty-one of his own cases to those already reported. In forty-three of his cases the lesion occurred on the lips, three on the tonsil, and one on the tongue, making a total of lesions about the mouth of seventy-seven per cent. of the whole number of cases. Ten of the lesions occurred on the hands, five infections were due to bites of infected persons, and kissing caused nine of the cases. Attention is called to the fact that extragenital chancre is often not correctly diagnosed until the occurrence of secondary symptoms and the frequent occurrence of the lesion on the lips or about the mouth is very apt to lead to innocent infection of others. Thus in his series a babe infected her father, he infected the mother and her unborn child; two men with lip lesions infected their wives; and an infant infected its mother who in turn infected her husband. The question of prophylaxis in this condition is of the utmost importance, and every effort should be made to establish the diagnosis at the earliest possible moment to render the victim harmless by prompt treatment. It was further brought out in this series of observations that the common drinking cup and the use of unclean dishes were responsible for not a few infections. Several of the chancres of the fingers occurred in physicians.

Atropine in Diagnosis of Typhoid and Paratyphoid Fevers.—H. Fairley Marris (*Brit. Med. Jour.*, November 25, 1916) states that a comparatively slow heart rate is characteristic of these diseases. Atropine is known to increase the rate of the normal heart by from twenty to forty beats a minute. He observed, however, that in typhoid and paratyphoid infections atropine largely failed to accelerate the heart. Extended observations on the effect of atropine on the heart rate in over 300 proved cases of these infections led to the elaboration of a simple diagnostic test for these diseases. The test is as follows: Not less than one hour after eating, with the patient lying horizontally and perfectly quiet, the pulse is counted minute by minute until the rate is found to be fairly uniform. Then two milligrams of atropine sulphate are injected into the triceps muscle and after a period of twenty-five minutes the heart rate is again recorded as before until its maximum has been passed. This will usually be within about fifteen to twenty minutes. If the increase in rate amounts to twenty or more beats per minute typhoid or paratyphoid is probably absent. Cases showing an increase of ten to twenty beats are uncertain, and those responding by an increase of ten beats or less are probably suffering from typhoid or paratyphoid. The results of this test were found to agree remarkably closely with the bacteriological or serological diagnoses in the cases studied. The test was found positive as early as the fifth day and as late as the hundredth day. Usually, however, the positive tests were found most constantly about the tenth day. Owing to the normally poor response to atropine in persons over fifty years old, the test should be taken with reserve after that age. It also was unreliable in those with cardiac affections. Antityphoid inoculation was found to give rise to a positive atropin test which did not last for more than ten weeks. The test was applied in a number of other febrile affections, in all of which it was found negative.

Diagnostic Value of Agglutination in Inoculated Persons.—E. W. Ainley Walker (*Lancet*, November 25, 1916) directs attention to the fact that the agglutination test for typhoid, paratyphoid A, or paratyphoid B. infection has not lost its diagnostic value as the result of prophylactic inoculation against these infections. The only changes inoculation has produced are the need for the adoption of accurately quantitative agglutination tests, the use of a standardized agglutinable culture, and the necessity for the repetition of the tests to determine the curve of agglutination. No arbitrary figures can be stated as indicating infection in inoculated subjects, but the discovery of a progressive rise, a progressive fall, or of both, in the curve of agglutination is certainly indicative of infection by the agglutinated organism. The maximum of the rise in the curve falls between the sixteenth and twenty-fourth days of the disease, most often from the eighteenth to twentieth days. It usually amounts to several hundred per cent. In a double infection with organisms of the typhoid and paratyphoid group two curves will be found, both rising and falling, but each independent of the other.

Experimental Syphilis.—Mathew A. Reasoner (*Journal A. M. A.*, December 16, 1916) reports on a large series of rabbits inoculated with each of twenty different strains of spirochetes obtained from human cases of syphilis, presenting different clinical features. The animal inoculations were made by different routes, but a uniform method of inoculation was adopted for each route. The results showed that there were certainly different strains of spirochetes, each having fixed characteristics as shown by differences in the lesions produced in the rabbits. Two strains had special affinity for the choroid and retina, others tended to produce keratitis when the infection became generalized. It was possible to produce a generalized syphilis in the rabbit by the repeated intravenous injection of spirochetes but not by local inoculation, which seemed to suggest that the local lesion was in the nature of a defensive response. Involvement of certain of the nervous structures in the rabbit was accomplished without intracranial inoculation. No morphological differences between the strains were discovered and no permanent alteration in the characteristics of any given strain followed prolonged culture and repeated transfers from rabbit to rabbit. Eight injections of spinal fluid from human cases of syphilis gave two positive results in rabbits.

Rhinitis in Infancy.—Roig Raventos (*Revista de Ciencias Medicos de Barcelona,* October, 1916) warns that rhinitis in children differs from that condition in adults from its contagious nature, its seriousness, and its occurrence in diseases peculiar to children. Gonococcus infection is not uncommon in the newborn, while hereditary syphilis and diphtheria are to be suspected in all cases. It must be remembered that syphilis may remain latent in parents and be quite virulent in their children. Erysipelas, hay fever, pneumonia, and meningitis are often accompanied by nasal discharge, and it is possible for cerebrospinal fluid in hydrocephalus to escape through the nose. Washing of the nostrils and nose with bichloride solution immediately after birth followed by installation of argyrol thrice daily into the nares for several days has been shown to greatly lessen the incidence of rhinitis in the newborn.

A Comparative Study of the Kidney Functional Tests.—L. Junius Desha, James Bassett McElroy, and Bryce W. Fontaine (*Southern Medical Journal,* December, 1916) summarize the results of their investigations as follows: 1. The nephritic test meal of Hedinger-Schlayer-Mosenthal has been used in thirty-six cases, about half of these being in private homes. In general, the results have demonstrated its value in diagnosis and prognosis. Care must be exercised not to attach too much importance to a deviation from a single published standard. 2. The results show a general agreement with the findings from the phenolsulponephthalein and nonprotein nitrogen determinations. While the test meal gives more information than either of the other two, it does not entirely replace them. 3. Among blood nonprotein nitrogen values higher than forty mg. per 100 c.c., there is noted an absence of relationship between the magnitude of the value and the prospective fatal determination. 4. The Greenwald modification of the Folin determination of nonprotein nitrogen has been used with satisfaction.

Ability of the Brain Tissue to Take Up Water in Delirium Tremens.—Frank Nuzum and E. R. Le Count (*Journal A. M. A.*, December 16, 1916) state that edema of the brain occurs in a certain proportion of the cases of delirium tremens, although it is absent in others. Certain other conditions are also marked by the occurrence of a similar edema. The explanation for this phenomenon was sought experimentally by a study of the power of a large number of brains, obtained at autopsy from persons dying of widely different conditions, to take up water. The hygroscopic power of normal brains was determined for control. Under the conditions of the tests the normal brain took up an average of 64.5 per cent. of its weight of water; the same figure was obtained for brains from patients who died of a number of general diseases. Brain tissue from persons who died from delirium tremens took up six per cent. more water than the normal, and from patients who died of cerebral hemorrhage, cerebral embolism, and uremia, the water imbibition was even greater. Alcohol poisoning in rabbits showed an analogous increase in the power of the brain to take up water. In all of the conditions in which the brain tissue was found to have an increased property for the absorption of water there had been a condition in the nature of an asphyxia. Asphyxia is known to increase the hydrogen ion concentration of the brain, and this, in turn, is known to be a factor which increases the power of colloids to imbibe water. It is suggested that this is the mechanism of the production of cerebral edema in the conditions mentioned.

Cerebellar Localization.—I. Leon Meyers (*Journal A. M. A.*, December 9, 1916) states that from a study of myograms of corresponding muscles of the two sides of the body in cats, both normal and previously operated upon with the production of various localized cerebellar lesions, he has reached certain definite conclusions in regard to the moot question of cerebellar localization and function. Combined with the methods just indicated was the specific stimulation of the cerebellum by means of repeated small doses of oil of absinthe. The cerebellar function was to inhibit, control, and regulate the activity of the motor cortex of the cerebrum and paracerebellar nuclei, toward which it bore a position somewhat analogous to that of the posterior root ganglia to the anterior horn cells of the spinal cord. The cerebellum was found to be functionally differentiated for the several muscle groups through the various motor centres. Cerebellar deficiency manifested itself by motor hyperfunction. In the experimental animals the cerebellar lesions were too small to produce any evidences clinically and their effects were only to be seen when the cerebellum was artificially stimulated by absinthe. It was suggested that the use of small doses of this agent or of alcohol might prove of considerable value in bringing out the manifestations of slight cerebellar lesions in doubtful cases in man.

Spinal Fluid in Cord Compression.—James B. Ayer and Henry R. Viets (*Journal A. M. A.*, December 9, 1916) review the literature of the findings in the spinal fluid in compression of the cord, showing that this subject has been largely neglected in this country, although studied more or less for some time abroad. In addition to the results recorded in the literature, those observed in twelve cases studied by them are recorded. All the evidence goes to show that the changes in the spinal fluid are fairly constant and quite characteristic in the presence of compression. The chief features are that the fluid is clear, very often decidedly yellow in color, contains a markedly increased amount of protein without corresponding increase in cell content and undergoes massive coagulation. Not all of these features are present in every case of cord compression, and in some small proportion of cases they may be entirely wanting. But in the great majority enough of the characteristics are present to be of much aid in diagnosis. The findings vary with the nature of the compressing agent and with its location. Thus in cases of acute compression the fluid is more likely to be yellow than in other types. The lower in the cord the compression is situated the greater the tendency for the fluid to present the complete syndrome, and the same is true of intramedullary and meningitic lesions. In no case among over 1,000 punctures in the absence of compression was a fluid obtained which presented the characteristics described.

Proceedings of National and Local Societies

THE MEDICAL ASSOCIATION OF THE GREATER CITY OF NEW YORK.

Stated Meeting, Held at the New York Academy of Medicine, April 12, 1916.

The President, Dr. THOMAS S. SOUTHWORTH, of New York, in the Chair.

Syphilis of the Bladder.—Dr. JAMES PEDERSEN, of New York, reported a series of twenty-six tertiary and fourteen secondary cases collected by Duroeux; twelve cases taken from more recent case reports, and five cases of his own, two of which, however, are not absolutely conclusive. Duroeux's thesis began with Morgagni's postmortem specimen (1767) and evidently includes all the cases recorded down to 1913. Reference to it and to the leading textbooks proved both the relative infrequency of the lesion and the frequency with which it had been overlooked hitherto or incorrectly diagnosed. By cystoscopy alone the diagnosis could not be made; it must be supported by at least one of the corroborating essentials; the history; the Wassermann reaction; syphilitic signs elsewhere in the patient, or the somewhat despised but useful treatment test.

The possible lesions of bladder syphilis were: 1. A more or less diffuse hyperemia from moderate to intense. It may be symptomless. 2. Punctate or more macularlike reddish spots—the so called "roseola" of the bladder. They may cause no symptoms. 3. An ulcer or ulcers. When characteristic, they were multiple in clusters; more or less elevated on an edematous mucous membrane; the edges definite and firm; the base grayish with necrotic or hemorrhagic debris. They may be mistaken for simple ulcers at one extreme or for tuberculous ulcers at the other. 4. Papillary growths, indistinguishable from benign papillomata or from the villosities surmounting a malignant base. 5. The gumma. By cystoscopy it could not be differentiated from either an infiltrating or a salient malignant growth. Unfortunately the incidence of bladder syphilis preponderated in the tertiary stage, when it is more difficult to discover signs that will corroborate the cystoscopic findings. Once the diagnosis had been established and proper treatment applied, the prognosis was exceedingly good.

Dr. EUGENE FULLER expressed his regret that he had been detained and did not arrive in time to hear the first part of the paper. The subject was interesting. There was no doubt that until very recently the bladder was supposed to be an organ which was wonderfully exempt from syphilitic involvement, and a large exemption can still be claimed for it. At the same time, a careful cystoscopic study such as Doctor Pedersen had been making will show cases with the lesions which he has so carefully detailed associated with a positive Wassermann, and such lesions will disappear under specific treatment. It seemed probable that in a good many of these cases syphilis may be found to act in conjunction with another lesion, perhaps with tubercle or some of the streptococcus infections. Gumma of the bladder was very rare, and when it did occur it was generally in connection with the fundus or prostatic region, extending into the bladder wall. There had been a few cases of a vesicorectal fistulous condition where the opening may have been caused by gumma.

Syphilis really played more havoc with the bladder through the spinal cord than by attacking the bladder itself, and the general practitioner should be on the lookout for the spinal conditions which affect the bladder. The topic was a little beyond the scope of the discussion, but it is such an important subject that a few words on the subject might be permitted. Generally, when there is lack of bladder control caused by syphilis it is due to spinal conditions. He reported the case of a patient who came to him some time ago after having been treated for four years for supposed prostatic disease, when the whole trouble was really with his spine. He was ataxic, as could be clearly recognized, and yet the treatment received had been focussed entirely on the prostate itself and the spinal lesion ignored. That error should be avoided carefully. This case had been so long wrongly treated that nothing much in the late stage could be done for the patient. Of course, after the correct diagnosis had been demonstrated, the man who had been treating the patient for so many years had to do a good deal of explaining: but that could not be avoided. One cannot always cover up a mistake as much as one would like, much as he might try.

Various conditions of the bladder may occur with these spinal lesions. Some twelve or fifteen years ago a man came to him at the City Hospital complaining of excruciating pain in his bladder on urination. That was before the days of the Wassermann test. He was cystoscoped, but nothing could be found to account for the pain. The man was suffering so much distress and discomfort that finally, in an effort to relieve him, Doctor Fuller cut into the perineum and put in a drainage tube, although it was against his principles ever to operate upon any one simply for the relief of symptoms when no tangible causative lesion could be demonstrated. It was a very good thing not to operate in that way, and this case served as an illustration. In this patient the lancinating pains of the vesical neck, of course, continued, and they were finally shown to be due to the lightning pains of ataxia. In two or three months the man developed a great deal of ataxia, although at the time he first came under observation his knee jerks were present, he did not have the Argyl Robertson pupil, and gave no history indicating syphilis.

Many of these early cases of ataxia will have difficulty in urination, and he had seen instances where a supposed stricture had been cut on the supposition that the urinary symptoms were due to that; whereas it was in reality one of the early symptoms of ataxia.

Doctor OSGOOD said that he had been very much interested in Doctor PEDERSEN's paper. Every one who has done any amount of cystoscopy has seen a number of these lesions in the bladder, but the

diagnosis was always made only by the treatment. These lesions were seen in the bladder, and resembled other lesions; but that was not a diagnosis of syphilitic cystitis, nor was that diagnosis established when syphilis was demonstrated in the body. In all the cases reported the diagnosis had been made because the lesions have disappeared upon the administration of the proper treatment.

Doctor Osgood said that he believed the diagnosis could be made, however, by removing a part of the lesion and demonstrating the spirochæta pallida in it. He had never seen any report of this having been done, and he had never done it himself. Spirochæta pallida have been demonstrated in syphilitic nephritis in one or two cases only, but it was highly probable that spirochæta pallida were present and that the diagnosis could be made by demonstrating them in such lesions.

In a diagnosis of a condition of this kind the cystoscope was necessary, and such a study as Doctor Pedersen had made has always helped the diagnosis, but the demonstration that the condition is syphilitic depends entirely upon the treatment, upon which Doctor Pedersen had cast some aspersions in his early remarks. That, however, was absolutely necessary, for one cannot make a diagnosis upon the appearance of the lesions only.

Doctor Barringer said that the members of the association were indebted to Doctor Pedersen for bringing this subject before them. He further said, that for ten or twelve years he had been looking for cases of syphilis of the bladder, largely because of the publications which have appeared, and he had had many discussions with Doctor Keyes concerning the subject. Doctor Barringer said that he had seen but one case in these ten or twelve years which he thought might be syphilis of the bladder, but he was so doubtful concerning it that he did not dare report it. He had made a little sketch of the case at the time, and he would be very glad to have Doctor Pedersen's opinion regarding whether or not it resembled his cases of syphilis of the bladder. The patient gave a history of frequent and painful urination, pyuria, and had an indeterminate Wassermann reaction—which at that time did not amount to very much. After that the patient was cystoscoped, and an ulcerated condition was found intermingled with macular congested spots on the bladder wall. This man was put upon intramuscular injections of salicylate, and his bladder condition absolutely cleared up, after which he disappeared from observation. About six months later, he heard from another urologist that the man had tuberculosis of the epididymis, and was not at all surprised, for it was not difficult to confuse tuberculous epididymitis and syphilitic testicle.

This was the only case he had ever seen in which he even suspected syphilis of the bladder, notwithstanding the fact that he had been looking for it for about ten years. It was interesting to know that Doctor Pedersen had seen five cases, although it would appear from the report that there might have been only three. He wished that Doctor Osgood had been less casual in describing the condition and the frequency thereof. These cases must be extremely rare, and specimens should be examined microscopically.

Eczema in Childhood.—This paper, by Dr. George W. Crary, of New York, appears in this issue of the Journal.

Dr. Charles Herrman said that he would limit his remarks to a discussion of the constitutional eczema of infants, which was a congenital anomaly, a disturbance of metabolism manifesting itself in a peculiar sensitiveness of the skin and mucous membranes. This tendency was generally known as the "Exudative Diathesis." Doctor Herrman some time ago had called attention to the fact that some of these infants had sprue shortly after birth as the first visible manifestation of this tendency. It was important to remember that it was the infant, not the mother, that was at fault, so that as a rule nothing was gained by giving the baby to a wet nurse or substituting artificial feeding. He believed that too much emphasis had been laid on the possibility that one particular constituent of the food, as fat, sugar, or salts, was at fault. Treatment based on such a view would fail if followed uniformly in all cases. This would explain the difference of opinion with regard to the value of Finkelstein's method, the view was too narrow. It might be compared with former conceptions in diabetes, where the carbohydrate metabolism was supposed to be solely at fault. Overfeeding was an important factor as we should expect in any disturbance of metabolism, but too great a loss in weight was not without danger. The relation to thyroid insufficiency was not proved. Doctor Herrman had observed a large number of cases of sporadic cretinism over a period of years, some had come under observation during the first six months of life, and he had not noted any special susceptibility to eczema in them. Thyroid extract had a marked effect upon the fat metabolism and possibly its beneficial effect in some cases might be explained in that way. Sudden death occurred in a few cases. Doctor Herrman had such a case in his hospital service some years ago. It was not necessarily associated with status lymphaticus, for in a great many cases the changes characteristic of that condition were absent. Death was probably due to degeneration of the heart muscle similar to that complicating diphtheria. A careful *microscopical* examination had shown such, and degenerative changes were also noted in the kidney. These changes were probably caused by bacterial toxines, indeed Hutinel had been able to demonstrate organisms in the blood during life in two cases. Doctor Herrman had seen a severe facial eczema in an infant in which the eye became infected and perforation of the cornea resulted, the child dying a short time after. A certain number of cases of constitutional eczema resisted all forms of treatment for some time. Most of these showed improvement after months without any radical change in the diet or method of treatment. In acne the same had been noted after puberty. To say that it may be due to a disturbance in the secretion of one or more of the so called ductless glands was merely hypothetical. We do not know. The more imperfect the feeding as to quantity and quality the more likely we are to obtain improvement by regulating the diet. When special idiosyncrasies to certain foods are present, these are excluded.

Stated Meeting, Held at St. George, Staten Island, on June 19, 1916.

The President, Dr. THOMAS S. SOUTHWORTH, in the Chair.

The Technic and Practice of Diathermia.—Dr. HEINRICH F. WOLF, of New York. This paper appears in this issue of the JOURNAL.

The Physics of the High Frequency Current.—Dr. ALBERT C. TEYSER, of New York. This paper was published in the JOURNAL November 4, 1916.

Doctor Branth said that he would like to cite a little history. Tesla, in the *Electrical Engineer*, December, 1891, expressed the opinion that high frequency currents might be serviceable in medicine D'Arsonval, in 1892, spoke of warming the tissues by this current, but did not refer to it as a remedy. In 1899, von Zeyneck spoke of diathermia. After that, eight years passed without a reference to diathermia, when Nagelschmidt, in Dresden, September, 1907, demonstrated before the Naturforscher-Verein true diathermia of arms and chest. Subsequently it came to light that von Berndt in Vienna had discovered the same in February, 1907. In our own country Doctor de Kraft, one of the members of this association, discovered the feature of elevated temperature by the passage of high frequency current through the body tissue, as far back as 1904.

The first step, the real passage of the high frequency current was, perhaps, discovered by him as far back as 1901; yet the elevation of temperature was overlooked by him at that time, and when he began to use high frequency current for *diathermia* it was after the aforesaid colleagues had written and spoken about it—and to them belonged the credit of priority.

What can diathermia do in medicine? We can warm the tissues between the two poles—even burn them if the current is strong enough and applied long enough. If diathermia—i. e., warming—only is desired, the bloodvessels will be dilated, more blood will pass, and so remove the debris and waste. During the recent epidemic of grippe, there were many cases of mastoiditis. If you take care that there is no pus in the auditory cavity—if the drum membrane is bulging and you puncture it—then apply the current, filling the ears with a piece of cotton soaked in salt solution, which will form a good conducting medium for the current; you can warm it to its deepest recesses and thus abort many cases of mastoiditis.

There are many cases of infected gallbladder, where there are no gallstones, that can be materially helped by the passage of the diathermic current. It is true that the treatment of gonorrhea by the diathermic current has not been satisfactory. The reason lies in the difficulty of the technic, for if you introduce a sound in the urethra and connect this sound with the current, the greatest density of the current will be at the point of emergence, and not distributed along the canal, and burns may result. If, however, the part is immersed in a cup filled with salt solution, you can distribute the high frequency current—or so called diathermic current—in a fairly equal quantity, and can warm all the parts and give material relief in some of these conditions. One of the most satisfactory uses is in old cases of gout. Kraft said that many of his patients had suffered with this condition for years and had never received any relief until they had a general diathermic current applied. It should be applied with large electrodes or with multiple electrodes, for the more numerous the electrodes the better. The action of radium is purely local (its greatest depth of penetration being from five to six cm.), and that beyond the area of inhibition there is stimulation, the observations on the treatment of neoplasms of the true cancerous type at St. Luke's Hospital having shown that, although the primary growth may be checked or apparently destroyed, the patients subsequently die of metastases.

Because of the lack of accurate means of control in the use of radium and its destructive effect on normal tissue, its use in the treatment of deep seated neoplasms has been discontinued. It is to be remembered that many of the tumors of mucous cavities are gummatous deposits and not true cancerous growths. The Wassermann test may show that the reputed cure was merely a dispersion of a gummatous deposit.

The so called burns, whether from radio active substances or x ray are due to the inhibitory action of the rays on the enzymes of the tissues, the condition produced being a local gangrene. The treatment of these burns consists in restoring the conditions required in the reaction of normal tissue by means of the local application of substances rich in available enzymes, such as white of egg, beef juice, etc. He expressed interest in Doctor Chase's experience in the use of high frequency currents for the relief of pain. In this form of therapy the heat and electrical energy combine to produce a direct acceleration of the normal action of the individual cells of the vascular tissue, thereby relieving pressure, which is so potent a factor in the production of pain.

Stated Meeting Held at the Academy of Medicine, May 22, 1916.

The President, Dr. THOMAS S. SOUTHWORTH, in the Chair.

Pyorrhea alveolaris.—Dr. R. G. HUTCHINSON, of New York.

Röntgenographic Diagnosis of Dental Infections.—Dr. SINCLAIR TOUSEY, of New York. This paper appears in this issue of the JOURNAL.

Infections of Bones and Joints.—Dr. PERCY W. ROBERTS, of New York. This paper appears in this issue of the JOURNAL.

Dr. WILLIAM H. HASKIN congratulated the society on the papers which had been presented, and agreed with Doctor Roberts that the teeth are not always the source of the various infections. He said that in appendicitis, pyosalpingitis, otitis media, etc., innumerable types of bacteria are constantly present, and it is also astonishing to see the changes which take place when the intestinal flora are cleaned up. He did not, however, agree with what Doctor Roberts had said about the teeth and the tonsils. He believed that the teeth were responsible in a hundred cases to one case where the tonsils were at fault.

Many slides and x ray pictures had been shown, and he had a few more representing the actual conditions in these cases. He also had had radiographs made of about 600 extracted teeth in order to study

the aspects of these root canals and the fillings, and in all these 600 teeth he had not found one with a complete canal filling, so that the assertion of being able to follow these canals down to the root is very rarely demonstrated. Many of these teeth have two or three apical openings. The angles and curves which they take in many cases, and the peculiar openings almost preclude the possibility of getting through the total root canal. It can be done in many instances, but not very often as compared with the number of failures. Even with the teeth extracted one cannot always tell how many canals there are with the radiographic film. So many questions arise in radiography that the true interpretation of the films is often impossible.

It was absurd to claim that such cases could be treated by instrumentation, or with ipecac, or any other drugs, and the keeping of such teeth in people's heads was a crime. Doctor Haskin then cited the case of a child who had an acute septic anæmia from abscess in the teeth. Three abscesses were found over two teeth in the upper jaw and one in the lower jaw with extensive necrosis of the superior maxilla.

He said he had a beautiful collection of gold work removed from such patients. One patient, a woman, with anæmia, had only twenty-five per cent. hæmoglobin, 1,300,000 red cells, and 4,200 white cells with eighty per cent. of small lymphocytes, all from ten abscessed teeth. She had been sick for two or three months and no one had ever examined her mouth. She had a very close call, and is still under treatment and it was too early yet to say whether or not she would recover. Look at the teeth; study them; they are the source of an infinite amount of trouble.

Dr. E. P. R. Ryan (D. D. S.) said that he had been asked to discuss the subject from the standpoint of the general dental practitioner, and had been wondering whether he could do so without being scared to death by seeing and hearing what was done in dental work and bridge work, but that he had been very much surprised at the manner in which the subject had been treated, more especially by the first paper on dental infections.

He did not intend to discuss the cause of septic disease or the virulence of bacteria carried from one part of the body to another, but rather to call attention to the presence of pus in the large percentage of mouths. While in the army he had examined thousands of recruits, young, vigorous men, and in all the cases examined where there were crowns and bridges pus existed in ninety-five per cent. It was up to the medical profession to say whether the presence of pus in the mouth has anything to do with systemic conditions. It is certainly there in an enormous number of cases, and can easily be demonstrated. Doctor Haskin had made one of the most important points of the evening when he said: "Look for pus."

Pictures had been presented showing that it was the height of absurdity to try to save the teeth in many of these cases. It was impossible to reattach them to the alveolar process, for they became foreign bodies as soon as they became separated from the surrounding tissues.

The dentists are not opposed to this movement. There is an idea that they are antagonistic to it because it will interfere with their work, but many have believed in it for years and have taken it very seriously, and still do so. You cannot, however, always take every tooth out of a patient's mouth. Not every dead tooth has an abscess; the x ray does not show that; but in conditions where there is a question of septic involvement in the mouth, the cause of the infection should be found and eliminated.

Letters to the Editors

FALLACIES ABOUT TUBERCULOSIS.

Buffalo, *December* 15, 1916.

To the Editors:

There are some points in the very valuable article by Dr. Maurice Fishberg in your issue for December 2nd that seem to warrant further discussion.

1. Granting that necropsies have shown for various European cities a healed tuberculosis in ninety per cent. of cases and that such lesions are common in this country, is it not going too far to hold that adult tuberculosis, apparently developing as a comparatively recent infection, is due to a lighting up of old foci? There are three possible fallacies to be considered in order. The supposedly dormant foci of healed tuberculosis are not actually demonstrated to be such in all or even the majority of instances. We simply induce this opinion by generalizing from a comparatively few accurate observations. Secondly, these foci do not necessarily include living tubercle bacilli. I am under the impression, but not positive, that it has been demonstrated tinctorially and microscopically that certain lesions have been tuberculous while inoculation into especially vulnerable animals has demonstrated the absence of living or at least virulent bacilli. Thirdly, the great majority of adult cases of tuberculosis show no connection with an infantile infection, even if this is assumed as probable or demonstrated *post hoc* at the necropsy. Why should we assume, either academically or to the exclusion of prophylactic measures which are at least harmless to the potential patient and at the worst cause some inconvenience and mental discomfort to the actual sufferer from tuberculosis, that a fresh infection plays no part in the subsequent development of the disease, as has been apparently demonstrated clinically in many instances? Even if we concede that the bacilli introduced *de novo* or their descendants are not the direct cause of the apparently fresh infection, there is nothing far fetched in assuming that they play a positive part in lighting up a dormant focus.

2. Either the analogy to the immunity conferred by smallpox is incorrect, or our beliefs as to different kinds or degrees of immunity require radical change. There is a term formerly used occasionally, that has lapsed into desuetude and that ought to be in common use—semelincident. If this word were kept before the medical profession, it would emphasize the sharp distinction between diseases such as the exanthemata generally which with very rare and usually doubtful exceptions, confer lifelong immunity, and certain other diseases like diphtheria, malaria, etc., which recur, on fresh exposure after what appears to be a complete annihilation of the infection. The immunity of semelincident diseases is apparently sometimes hereditary. At least, if the mother has an attack during pregnancy and does not abort, the child is usually "naturally immune" to the same infection. Whether there is any radical difference between the immunity conferred by different diseases is rather an academic question. The practical fact is that with few exceptions some infections confer a lifelong immunity after an attack, while others leave the patient susceptible after a comparatively brief interval. The Schick test leads to the hope that the duration of the period of immunity can be determined for infections in general. Clinical experience has apparently shown that tuberculosis is not a semelincident disease.

3. Where has the author acquired the experience that "city dwellers . . . only exceptionally manifest active tuberculous disease?" Tuberculosis certainly does occur frequently and in severe form among city dwellers, among Indians on reservations where opportunities for infection and whatever immunity might develop, have been afforded for several generations, and in country dwellers in houses and neighborhoods which provide just as good opportunities for the influence of repeated, mild exposures as exist in cities. That constant exposure for many generations does afford a considerable degree of immunity, is well established, but it is scarcely safe to conclude that a given subject, merely because it is assumed as probable that he has had a mild infection with tuberculosis in infancy, may with impunity be subjected to opportunities for massive infection at a later period.

4. The fact remains that tuberculosis is not so common a disease, in recognizable, serious form as it was even a generation ago. Consumptives are not so numerous in our personal acquaintance, in our chance meetings in public places, in our clientele, as they were. Statistics agree pretty generally, that tuberculosis deaths have fallen off at almost the same rate as the general mortality. Approximately we have fifteen in 1,000 general death rate compared with a twenty in 1,000, about one-tenth being due to tuberculosis in either case.

5. Doctor Fishberg's contention regarding the inefficiency of therapeutic measures is largely true. However, hygienic and dietetic treatment have accomplished a great deal. The fact that the majority of the profession agree that, from the practical standpoint, specific treatment with various bacterial products is thus far a failure should be considered, not merely by itself, but in relation to the acquirement of immunity. If men of the highest technical attainments, with ample clinical material and many years' experience, lay claim to only provisional success with tuberculins of various kinds, why do we expect that purely accidental exposure to tubercle bacilli should produce a dependable immunity?

A. L. Benedict, M.D.

Book Reviews

[We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.]

Arteriosclerosis. A Consideration of the Prolongation of Life and Efficiency After Forty. By Louis Faugeres Bishop, A.M., M.D., Clinical Professor of Heart and Circulation Diseases, Fordham University, School of Medicine, New York City, etc., London and New York: Henry Frowde (Oxford University Press) and Hodder & Stoughton, 1914. Pp. x-383. (Price, $3.50.)

This work is a sincere effort to place before the profession in a condensed form our knowledge of arteriosclerosis. Necessarily it lacks the details of the more ambitious works and bears some evidence of having been somewhat rapidly put together. The author states that arteriosclerosis is much more frequent than formerly. This is hardly susceptible of proof. To be sure, no one within the direct knowledge of man has reached the age of Methuselah, nor does any one of our generation seem destined to do so, but with the evolution of man the intellectual conflicts have for the most part supplanted the physical, notwithstanding the present war. Psychic strain is probably as much, if not more, of a factor etiologically than physical effort. Physical effort admittedly results in cardiac hypertrophy and must have been common among our ancestors, but at the same time exercise results in more perfect oxidation. The sedentary life with mental effort would seem more pernicious therefore than the other. In the following quotation the author sounds a note that must strike a responsive chord in many clinicians: "The author craves the indulgence of protein chemists and bacteriologists whose territory he has invaded in the search for the truth about arteriosclerosis, and hopes they will pardon technical inconsistencies that he has risked in an attempt to explain his experience in clinical medicine. The ever increasing demands of practice have made it impossible to go back, in person, to the laboratory for confirmation. Clinical philosophy has long since yielded the field to the technician, and no real practitioner would dispute ground with the youngest laboratory man when armed with test tube and statistical facts. But sick humanity is clamoring for relief and will not wait for the technicians to slowly complete their tasks and in due time reveal their treasures of knowledge and present them for use. The sick man says, 'Go seize the precious truth and use it now.'"

The work is very practical in its application, numerous case reports being referred to, and illustrations of x rays and pulse tracings with blood pressure records and every evidence of a wide knowledge of the literature. His chapter on the chemistry of proteins should be read with a due recognition of the fact that our knowledge on this topic is changing almost from day to day. The work is concluded by an interesting reference to arteriosclerosis in life insurance.

Interclinical Notes

A new feature of the *Outlook* is announced in the issue of that periodical for December 20th, whereby it will be used in the future as a sort of textbook for both current history and good English in the schools of Providence, R. I., and later, it is hoped, in the schools of other cities. Many people think that English can take care of itself, but it is a fact that many uncalled for changes are due to carelessness in newspaper and other offices. Witness the growing use of "deduct" for "deduce," "lay" for "lie," "due" where "owing" should be used (adverbially). "Disinterested" is becoming confounded with "uninterested." We find that many of our contributors cannot use the word "after;" at least, they invariably write "following," an unwieldy substitute. We wish the carefully edited *Outlook* good luck in its new mission.

* * *

The story of Hopewell, Va., is a feature of the *Survey* for December 2nd. Under the stimulus of the establishment of a powder factory within the town's limits, lots leaped in price from ten dollars to one thousand dollars, until the construction work was completed, when prices fell to about their former level. The only hospital, the story says, is maintained by a doctor who is in constant hot water for lack of a license to practise in Virginia; he has made a notable fight against vice. The powder people have kept typhoid and malaria away from Hopewell, but just outside the city limits is a negro settlement which gets water from a polluted well, and plenty of typhoid, too. The *Survey* says the company has no control over this suburb; why does it not buy the territory? It is thought that soon the powder works will become dye works.

* * *

There is a wonderful picture in *Leslie's* for December 14th of the Yale Bowl, where Yale defeated Harvard at football for the first time in eight years. Another good picture is that of the 50,000 people watching the army and navy game in which the former was victorious. The wonderful Red Cross dogs are shown on page 659; one of them is submitting philosophically to the bandaging of its wounds by a human member of the organization. The pictures of mascots and pets belonging to the soldiers are rather pathetic.

* * *

"Sinapis" in his department, "At the Periphery," in the *Medical Press* for November 15th, remarks as follows concerning some forms of irregular practice: "A correspondent writes: 'What is all this fuss about osteopaths, bone setters, and manipulators? Do we not employ mechanical methods ourselves? Are there no such things as masseurs, gymnastic institutes, Zander Institutes, physical exercise establishments and bathing establishments all of which are openly quacked for the pecuniary advantage of their promoters, which are nevertheless recognized and recommended by all the mandarins? And, if the answer is in the affirmative, will you tell me what is the difference in principle between any and all of them?' Although, because it begs the whole question, I must demur to the word 'quacked,' the correct answer is clearly 'in the affirmative'; and the difference in principle is not in reality very far to seek. It is the details which are difficult. The difference, it

seems to me, resides in the principles on which these various things are run. If they are run purely as therapeutic institutes, which carry out therapeutic measures indicated by medical men in each individual case, and refuse cases which do not come through a member of the profession, then, though they be run for profit, they are quite free from the reproach of quackery. They are on precisely the same level as a chemist who dispenses a prescription."

Meetings of Local Medical Societies

MONDAY, *January 1st.*—West Side Physicians' Economic League; Clinical Society of Nose, Throat, and Lung Hospital; German Medical Society of the City of New York; Clinical Society of the New York Polyclinic Medical School and Hospital; Brooklyn Hospital Club; Hornell Medical and Surgical Association; Niagara Falls Academy of Medicine; Utica Medical Library Association.

TUESDAY, *January 2nd.*—New York Academy of Medicine (Section in Dermatology); New York Neurological Society (annual); Amsterdam City Medical Society (annual); Lockport Academy of Medicine; Society of Alumni of Lebanon Hospital, New York; Syracuse Academy of Medicine; Buffalo Academy of Medicine; Ogdensburgh Medical Association; Oswego Academy of Medicine (annual); Broome County Medical Association; Medical Society of the County of Yates (annual); Medical Society of the County of Cattaraugus (annual).

WEDNESDAY, *January 3rd.*—Brooklyn Society for Neurology; Society of Alumni of Bellevue Hospital; Harlem Medical Association; Bronx Medical Association; Elmira Academy of Medicine; Psychiatrical Society of New York (annual); Society of Alumni of St. John's Hospital, Brooklyn; Schenectady Academy of Medicine; Medical Society of the County of Genesee.

THURSDAY, *January 4th.*—New York Academy of Medicine; Brooklyn Surgical Society; Practitioners' Club, Buffalo; Geneva Medical Society (annual); Glens Falls Medical and Surgical Society.

FRIDAY, *January 5th.*—New York Academy of Medicine; New York Microscopical Society; Gynecological Society, Brooklyn; Practitioners' Society of New York; Corning Medical Association; Alumni Association of Roosevelt Hospital.

Official News

United States Public Health Service:

Official list of changes in the stations and duties of commissioned and other officers of the United States Public Health Service for the seven days ending December 20, 1916:

BEAN, W. S., JR., Assistant Surgeon. Directed to proceed to Spartanburg, S. C., and report to Surgeon Goldberger for duty in investigations of pellagra.

CARTER, H. R., Assistant Surgeon General. Leave of absence without pay for two months from October 20, 1916, amended to cover period October 20 to December 10, 1916.

COBB, J. O., Surgeon. Directed to proceed to Princeton, Ind., for conference relative to suspected case of leprosy.

DERIVAUS, R. C., Assistant Surgeon. Ordered to report to Bureau, Washington, D. C., en route to station from New York, for conference on malaria investigations.

EDMUNDS, M. C., Assistant Surgeon. Directed to report to Surgeon Goldberger, Spartanburg, S. C., for duty in investigations of pellagra.

FAGET, F. M., Assistant Surgeon. Directed to report to the commanding officer of the Coast Guard cutter *Androscoggin* at Boston, Mass., for duty.

HOLT, J. M., Surgeon. Granted ten days' leave of absence from December 26, 1916.

KEARNY, R. A., Passed Assistant Surgeon. Granted fifteen days' leave from December 21, 1916.

MILLER, K. E., Assistant Surgeon. Directed to proceed via Washington to Edgecombe County, N. C., and other places for investigation of rural health organization and administration.

PIERCE, C. C., Senior Surgeon. Granted seven days' additional leave from December 23, 1916.

PRATHER, D. J., Assistant surgeon. Relieved from duty at the Hygienic Laboratory, Washington, D. C., upon completion of special duty under Bureau orders of October 27, 1916, and directed to proceed to Ellis Island, N. Y., Immigrant Station for duty.

ROTH, G. B., Technical Assistant. Detailed to attend meetings of American Physiological Society and American Society for Pharmacology and Experimental Therapeutics at New York, December 28-30, 1916.

SEIDELL, ATHERTON, Technical Assistant. Detailed to attend meetings of Federation of American Societies for Experimental Biology at New York, December 27-30, 1916.

SMITH, H. F., Assisant Surgeon. Upon instructions from Surgeon Lavinder, will proceed to Wilmington, Del., to collect epidemiological data necessary in studies of poliomyelitis.

STIMPSON, W. G., Assistant Surgeon General. Granted four days' leave of absence during month of December.

SWEENEY, A. R., Assistant Surgeon. Relieved from duty at Galveston, Texas, quarantine station; will proceed to St. Louis Marine Hospital for duty.

WAGENBACH, W. F., Assistant Surgeon. Directed to proceed to Spartanburg, S. C., and report to Surgeon Goldberger for duty in investigations of pellagra.

WARREN, B. S., Surgeon. Directed to proceed to New York City for special temporary duty.

Births, Marriages, and Deaths

Died.

BUCK.—In Cincinnati, Ohio, on Wednesday, December 13th, Dr. Jirah Dewey Buck, aged seventy-eight years.

BURLEIGH.—In Waverly, Mass., on Friday, December 15th, Dr. Charles Burleigh, aged sixty-one years.

CHURCHILL.—In Reedsburg, Wis., on Thursday, December 7th, Dr. Wesley R. Churchill, aged seventy-one years.

DAVIS.—In Bakersfield, Cal., on Thursday, December 7th, Dr. Charles Alva Davis, aged fifty-five years.

DEADERICK.—In Johnson City, Tenn., on Monday, December 4th, Dr. Eugene L. Deaderick, of Jonesboro, aged seventy-three years.

DUMORTIER.—In South Norwalk, Conn., on Friday, December 15th, Dr. Jean J. Dumortier, aged fifty-one years.

EISEMAN.—In Latrobe, Pa., on Tuesday, December 12th, Dr. Reuben Eiseman, aged fifty-four years.

FISHER.—In Fitchburg, Mass., on Friday, December 15th, Dr. Jabez Fisher, aged ninety-two years.

GAUCHER.—In Putnam, Conn., on Sunday, December 17th, Dr. J. A. Gaucher, aged twenty-six years.

GRISARD.—In Winchester, Tenn., on Thursday, December 7th, Dr. James W. Grisard, aged sixty-seven years.

HALL.—In Knowlesville, N. Y., on Sunday, December 10th, Dr. Erasmus D. Hall, aged eighty-five years.

HOISINGTON.—In Boston, Mass., on Thursday, December 14th, Dr. Walter L. Hoisington, aged fifty-five years.

IRVINE.—In San Francisco, Cal., on Monday, December 4th, Dr. E. Lloyd Irvine, of Portland, Ore., aged thirty-three years.

JOHNSTON.—In Richmond, Va., on Thursday, December 21st, Dr. George Ben Johnston, aged sixty-four years.

KNAPP.—In New York, N. Y., on Monday, December 18th, Dr. John B. Knapp.

LAMBERT.—In Port Jervis, N. Y., on Friday, December 8th, Dr. Emerson B. Lambert, aged sixty-four years.

O'NEIL.—In Providence, R. I., on Thursday, December 7th, Dr. John E. O'Neil.

PALMER.—In Hornell, N. Y., on Monday, December 11th, Dr. William E. Palmer, aged seventy-eight years.

PORTER.—In Kansas City, Mo., on Thursday, December 14th, Dr. David Rittenhouse Porter, aged seventy-eight years.

SKINNER.—In Chambersburg, Pa., on Monday, December 18th, Dr. William Francis Skinner, aged forty-nine years.

WALKER.—In Providence, R. I., on Tuesday, December 12th, Dr. Edward F. Walker, aged fifty years.

The Health Department's Grading of Restaurants.—The health department's inspection and reinspection of the city's restaurants is continuing unabated, and while no figures were given out, it is evident that the grading plan introduced by the Bureau of Food and Drugs is proving a great popular success. In order not to be unfair to the restaurant keepers, the department will hereafter not actually grade a restaurant until after reinspection. This will meet the objection that minor violations have resulted in some of the recent "bad" gradings. But a restaurant which then fails to comply with the department's regulations need expect little mercy in the way of publicity.

The following telegrams from recognized authorities in pure food work approving the department's plan were made public:

FARGO, *N. D., June 20, 1916.*

Department of Health,
New York city.

Grading system and sanitary score card have done more than food law to correct food evils and protect the health of consumers. There is rivalry among business places for best sanitary score and a general cleaning up and clean foods. I know of nothing which will do so much for health of people.

E. F. LADD, State Food and Drugs Commissioner, North Dakota.

INDIANAPOLIS, *June 20, 1916.*

Department of Health,
New York city.

Indiana has graded hotels and restaurants with marked success since passage of sanitary law six years ago. Result obtained meets approval of hotel keepers and public. Know of no other way to secure necessary improvements.

HARRY E. BARNARD, State Food and Drugs Commission, Indiana.

England Wars on Cancer.—That the policy of "business as usual" applies to constructive efforts for the prevention of disease in England is evident from the publication by the Central Midwives Board as recently as March 16, 1916, of a new circular on cancer of the breast. The practice of midwifery in England and Wales is controlled by this board, and the circular is the newest of a series issued for the instruction of all women practising this profession and registered with the board as required by the law. The leaflet on cancer of the breast was prepared by the chairman, Dr. F. H. Champneys. F. R. C. P., and is distributed to the public as well as to midwives.

Pointing out that cancer of the breast unless treated by early removal always ends in death, Doctor Champneys states that the disease is at first only in the part affected and not in the system. "Every day and even every minute," the circular says, "is of importance and no time at all should be lost. The earliest symptom is a lump in the breast which is usually painless and may be quite small. It may remain without seeming to grow for some time. The only cure is early removal. Although it is often easy to be sure that a lump is cancerous, many lumps which begin by being innocent turn into cancer sometimes after many years."

Doctor Champneys advises that all lumps except those caused by undoubted and recent inflammation should be removed as soon as they are found, and counsels all women who discover a lump in the breast to consult at once a surgeon who is in the habit of dealing with them. If the lumps are not removed and are cancerous, the disease sooner or later spreads through the body and becomes incurable, while if the lumps are not cancerous, they may become so. "The removal of an early lump," the leaflet goes on to say, "is generally simple, and if microscopic examination should show afterward that it was not cancerous, a danger for the future will have been averted and the anxiety of the patient and her friends will be relieved." From such an operation there is generally "practically painless recovery in a few days. If the lump proves to be cancerous, however, a further operation is necessary, which, if undertaken early, saves many lives."

According to Doctor Champneys, if women would follow the foregoing advice, much loss of life, many regrets when too late, and much misery would be saved.

A School for Health Officers.—Sixty courses of study will be given next year in the School of Health Officers conducted by Harvard University in conjunction with the Massachusetts Institute of Technology, according to the catalogue for 1916-17, just issued. The faculty will be composed of fifty members. The principal object of the school is to prepare young men for public health work and especially to fit them to occupy administrative and executive positions, as health officers or members of boards of health. To this end, both Harvard and the institute will offer lectures, laboratory work, and other forms of instruction, and men from national, State, and local health agencies will speak. The subjects embraced in the course of study have been selected to cover a wide range, including medical, biological hygienic, and engineering sciences, together with practical health administration.

The opportunities for the practical study of public sanitation offered to students in the School for Health Officers are exceptional on account of location and the resources of Harvard and the Institute of Technology. The different courses to be given are divided into ten groups dealing with various phases of sanitation problems. The departments of public health administration and sanitary biology and chemistry are among the strongest departments of the school. The certificate in public health (C. P. H.) will be granted to candidates who have satisfactorily completed the studies in their approved schedule, who have spent not less than one academic year in residence, and who have otherwise complied with all requirements.

New Publications Received

A Manual of Gynecology and Pelvic Surgery. For Students and Practitioners. By ROLAND E. SKEEL, A. M., M. S., M. D., Associate Clinical Professor of Gynecology, Medical School of Western Reserve University; Visiting Surgeon and Gynecologist to St. Luke's Hospital, Cleveland, etc. With Two Hundred and Eighty-nine Illustrations. Philadelphia: P. Blakiston Sons' Company, 1916. Pp. xiv-680. (Price, $3.)

Formulaire des Médications Nouvelles et des Traitements Nouveaux. Pour 1916. Par Le Dr. H. GILLET, ancien interne des Hôpitaux de Paris, Chef de Service à la Policlinique de Paris. Dixième Edition entièrement Refondue. Paris: Librairie J. B. Baillère et Fils, 1916. Pp. xx-324.

Rules for Recovery from Pulmonary Tuberculosis. A Laymen's Handbook of Treatment. By LAWRASON BROWN, M. D. Second Edition, Thoroughly Revised. Philadelphia and New York: Lea & Febiger, 1916. Pp. 184. (Price, $1.25.)

A List of American Organizations for Cripples. Revised to April 1, 1916. Compiled by DOUGLAS C. MCMURTRIE. New York, 1916. Pp. 7.

Miners' Nystagmus. By FREDERICK L. HOFFMAN. Department of the Interior, Franklin L. Lane, Secretary. Bureau of Mines, Van H. Manning, Director. Washington, 1916. Bulletin 93. Pp. 67.

Cerebrospinal Meningitis. Report of the Departmental Medical Committee. Department of Public Health, Victoria. December, 1915. Melbourne: Albert J. Mullett. Pp. 21.

Collectanea

Infant Mortality Still High.—The enormous waste of infant life which still goes on, although medical science has done and is doing much to arrest it, is shown by the exceedingly high death rates which prevail among infants under one year of age. According to tables prepared by the Bureau of the Census, Department of Commerce, of 100,000 native white boy babies born alive, 4,975, or almost five per cent., die during the first month, and 12,602, or 12.6 per cent., die within one year. The girl baby's chance of life is considerably better, the death rate among native white females during the first month being 3,894 per 100,000 born alive, or less than four per cent., and during the first year 10,460 per 100,000, or nearly 10.5 per cent.

On its first birthday, however, the likelihood that a child will die within the year is only about one fourth as great as it was at birth, the death rate among native whites during the second year being 2,841 per 100,000 for males and 2,610 per 100,000 for females. The rate continues to decrease until the twelfth year of life—that is, the period between the eleventh and twelfth birthdays—during which it is only 228 per 100,000 for males and 198 per 100,000 for females. This, the figures indicate, is the healthiest year of life among native whites. Thereafter there is a continuous increase in the death rate from year to year. During the forty-eighth year of life, in the case of native white males, it is 1,267 per 100,000, or almost exactly what it was during the third year, 1,266; during the sixty-second year it is 2,919 per 100,000, or a little more than during the second year, 2,841; and during the eightieth year it is 12,184, or somewhat less than during the first year, 12,602. Similarly, among native white females the rate during the fiftieth year, 1,120, is a little less than during the third year, 1,144; during the sixty-third year it is 2,548, or somewhat less than during the second, 2,610; and during the eightieth it is 10,901 per 100,000, or a little more than during the first, 10,460. The native white man at the age of 102 and the native white woman at ninety-nine years have approximately the same prospect of dying within one month that they had at birth.

A Splendid Measure of Cooperation of the Brewers' Board of Trade.—In December, 1915, the Division of Industrial Hygiene of the Bureau of Preventable Diseases was informed that two employees working for a certain contractor had become severely ill from wood alcohol poisoning and had died on December 2nd and 3rd respectively, after an illness of twenty-four hours. These men had been employed in varnishing with shellac the interior of beer vats. It was subsequently ascertained that this varnish contained more than fifty per cent. wood alcohol. Upon investigation of these two cases, a third case was discovered in a patient who was being treated under the erroneous diagnosis of lead poisoning, in one of our large hospitals. The third man had likewise been employed in varnishing beer vats for the same contractor, and had shown symptoms of poisoning on December 4th. In common with the others he had severe epigastric pains, anorexia, stertorous breathing, and loss of consciousness. This man, more fortunate than the others, made a slow recovery, but was left with blurred vision.

These are not isolated instances of wood alcohol poisoning, for from time to time cases from the same cause have been reported to the State Labor Department, the National Association for the Prevention of Blindness, and the health department. The cases recently brought to light, stimulated efforts on the part of this department to do away with wood alcohol for varnishing vats in breweries. Accordingly, the commissioner addressed a letter to all breweries with offices in the city of New York, asking their cooperation.

The following letter received from the secretary of The Lager Beer Brewers' Board of Trade of New York and Vicinity, affords great satisfaction to those who realize how frequent and great has been the danger from the inhalation of methyl alcohol in the varnishing of vats:

April 13, 1916.

H. Emerson, Commissioner, Department of Health, Walker and Centre Streets, New York, N. Y.:

I beg leave to advise that at a meeting of the members of this Board of Trade, held yesterday, the 12th instant, a resolution was adopted prohibiting the use of methyl alcohol in connection with the varnishing of vats in their plants. For your information I herewith enclose a membership list of this association.

(Signed) CHAS. J. WARNER, Secretary.

Thirty-seven New York city brewers and nine New Jersey brewers, members of the Brewers' Association, have accordingly pledged themselves to exclude methyl alcohol from use in their plants for varnishing purposes.

Health Insurance.—Twenty-five out of every 1,000 employees in American industries, according to recent statistics, are constantly incapacitated by sickness, the average worker losing approximately nine days each year on this account. This "non-effective rate" for the great army of industrial workers in the United States barely suggests the total money loss to employers and employees. The lessened efficiency, the effects of reduced earnings in time of sickness, as well as the cost of medical attention, and the economic loss from deaths, swell the cost to industry and to the Nation to almost incalculable figures. That much of this loss is nothing less than preventable waste and that this waste can be largely reduced by a properly conducted system of governmental health insurance for wageworkers are conclusions set forth in *Public Health Bulletin No. 76*, containing the results of a study of Health Insurance—Its Relation to the Public Health, just issued by the Public Health Service.

The preventive value of health insurance receives especial emphasis in this study. "Any system of health insurance for the United States or any State should at its inception have prevention of sickness as one of its fundamental purposes," says the bulletin. "This country should profit by the experience of European countries, where prevention is being recognized as the central idea necessary to health insurance, if health insurance is to attain its greatest success in improving the health and efficiency of the industrial population."

Such a system, it is pointed out in the bulletin, would

1. Provide cash benefits and medical service for all wage earners in times of sickness at much less cost than is now possible. Adequate medical relief would thus be placed within the reach of even the lowest paid workers, who are most subject to ill health.

2. Distribute the cost among employers, employees, and the public as the groups responsible for disease causing conditions and afford these groups a definite financial incentive for removing these conditions. This can be done by means of small weekly payments from employees, supplemented by proportionate contributions from employers and government at a rate reducible in proportion to the reduction of sickness.

3. Become an effective health measure by linking the cooperative efforts of the three responsible groups with the work of National, State, and local health agencies, and by utilizing these agencies in the administration of the health insurance system.

4. Afford a better basis for the cooperation of the medical profession with public health agencies.

5. Eliminate the elements of paternalism and charity giving by making employees and the public, as well as employers, joint agents in the control of this fund.

"A governmental system of health insurance," concludes the study, "can be adapted to American conditions, and when adapted will prove to be a health measure of extraordinary value."

Committee of American Physicians for Medical Preparedness.—This committee, which was organized in Chicago last April, has carefully formulated and matured plans for the purpose of ascertaining the extent of civilian medical resources and of organizing and utilizing them for national defense. The first duties to be undertaken by the committee are: To aid the medical departments of the United States Army and Navy by making a comprehensive inventory of the special qualifications of individual civilian physicians throughout the country; to cooperate with the National Committee of the American Red Cross in bringing that organization up to the highest standards of medical ideals and to aid in the organization of Red Cross units throughout the country; a practical inventory of all civilian medical resources; research work and careful investigation along many lines relating to the subject of efficient medical preparedness. The Committee of American Physicians for Medical Preparedness consists of a National Committee composed of six ex officio members, thirty members, and a number of associate members representing important subjects closely allied to medicine. Honorary and ex officio members of the national committee are: Dr. William C. Gorgas, surgeon general, United States army; Dr. William C. Braisted, surgeon general, United States navy; Dr. Rupert Blue, surgeon general, Public Health Service. Ex officio members: Dr. Rupert Blue, president American Medical Association; Jefferson R. Kean, colonel Medical Corps, U. S. A., director General Military Relief American Red Cross; and Dr. Samuel J. Mixter, president American Surgical Association. The executive committee consists of the following members: Dr. Albert Vander Veer, Dr. Fred B. Lund, Dr. Franklin H. Martin, Dr. George E. Brewer, Dr. William S. Thayer, Dr. J. M. T. Finney, Dr. George W. Crile, Dr. William J. Mayo, Dr. Robert G. Le Conte, and Dr. Frank F. Simpson. The general committee is composed of the following members: Dr. Frank Billings, Dr. Joseph C. Bloodgood, Dr. Rudolph Matas, Dr. Lewis S. McMurtry, Dr. Charles A. Porter, Dr. Emmett Rixford, Dr. John F. Binnie, Dr. George E. de Schweinitz, Dr. Charles L. Gibson, Dr. Edward Martin, Dr. John B. Murphy, Dr. Albert J. Ochsner, Dr. Charles A. L. Reed, Dr. Hubert A. Royster, Dr. Richard P. Strong, Dr. Victor C. Vaughan, Dr. Charles H. Mayo, Dr. Henry Sewall, and members of the executive committee. Dr. William J. Mayo, of Rochester, Minn., is chairman of the committee, and Dr. Frank F. Simpson, of Pittsburgh, Pa., is secretary.

Collectanea

Sure Cures for Infantile Paralysis.—Benevolent and unquestionably disinterested readers have been offering the *New York Tribune,* says that journal in its issue for July 12th, a great variety of proposals for the treatment and control of poliomyelitis. Hydrotherapy, vegetarianism, sugar and eggs, faith, salt water, and a vast number of other things are suggested with great confidence, the letters usually beginning: "Infantile paralysis, in my opinion, is bred from the same source as summer complaint"; or, "The prevailing epidemic is, I believe, a form of grip"; or, "The present plague can easily be arrested by following these simple rules"; or, "This epidemic is largely psychological," etc.

It is not possible and it would clearly be unprofitable to publish all these interesting opinions or guesses. They come for the most part from well meaning people who make no pretense whatever to the slightest experience and many of whom are quite willing to admit that they have never treated or even seen a case in their lives. It is interesting to observe that the most dogmatic are not at all embarrassed in confessing their ignorance, and the assurance that a great deal of thought and labor has been expended in studying the disease does not impress them in the least. They smile patiently at all doubts about their qualifications and proceed to descant upon the virtues of their invaluable remedies.

Most of these people in ordinary times make up the rank and file of the societies of antivaccinists, antivivisectionists, and so forth. They have a profound distrust in pathologists, bacteriologists, and physicians. They believe that the whole medical profession is in a conspiracy against common sense, and that the doctors are determined to encourage illness in the world because it is by illness they make their living. It is therefore quite natural that they should disregard all professional attempts to solve the problem of poliomyelitis, quite natural that they should be very eager to cure the world in their own way.

Unfortunately, it is impossible to treat them with the consideration they demand. They can hardly express more disagreement with the views of the orthodox than they do with one another, and to let them all have their say would be confusing, even if it were otherwise desirable, which it is not.

An Esophageal Cast.—Dr. F. H. Jacob, of Nottingham, reported to the *Lancet* for May 13, 1916, an unusual case. The patient, who had recently enlisted in the army, went to see him on account of a sore throat. The pharynx presented a gray, sloughing appearance. He brought with him some stuff which he had vomited on the previous day. On floating this in water the doctor found it to consist of a cast of the whole of the esophagus and of the pharynx and nasopharynx. He cut sections and found it to consist of the epithelial lining of the esophagus. The patient gave a history of having had two similar attacks previously—one a year ago and the other six years ago. He said that he had not been able to swallow properly for six years, something always seemed to catch him in the throat. When eating meat he had to chew it thoroughly and never hurry. Each attack commenced during a meal, and felt as though something sharp was cutting his throat, then he vomited up blood, and after that the skin. The throat was very sore for a fortnight, then got right again. Ten days later his throat was nearly recovered. He had had no previous illness except eczema as a baby. The Wassermann reaction was completely negative.

Dr. Jacob appends notes of some previous cases. 1. In the *Lancet* for January 5, 1901, p. 26, Dr. Nathan Raw recorded a case of membranous esophagitis with expulsion of a complete cast of the esophagus. In this case the esophagitis was ascribed to drinking neat brandy, whisky, and rum. Raw mentions in his paper that exfoliative or desquamative inflammation of the esophagus, or œsophagitis dissecans superficialis was first described by Birch-Hirschfeld in Ziemssen, VIII, p. 140. 2. At the Royal Society of Medicine, section in laryngology, meeting on April 4, 1913, Mr. G. N. Biggs showed an almost complete cast of the epithelial lining of the esophagus, which was vomited three days after the patient had swallowed one ounce of chloroform. Rectal feeding was employed. Esophagoscopy, three months later, gave no indication of contraction. 3. Osler and McCrae, second edition, 1915, p. 80. John McCrae describes various causes of phlegmonous esophagitis; records a case reported by Neisser and a case of Stern's, where a cast thirteen cm. long was expelled; alluding also to Birch-Hirschfeld's original case in which a twenty cm. cast was expelled three days after the onset of the first esophageal symptoms; the patient promptly recovered. 4. There is a short allusion in the *Twentieth Century Practice of Medicine,* by Fitz, of Boston.

S., Professor of Surgery in the Northwestern University; etc. The Practical Medicine Series. Comprising Ten Volumes on the Year's Progress in Medicine and Surgery. Under the General Editorial Charge of CHARLES L. MIX, A. M., M. D., Professor of Physical Diagnosis in the Northwestern University Medical School. Series 1916. Chicago: The Year Book Publishers. Pp. 620.

Collectanea

The Austro-German Medical Congress at Warsaw, May 1st and 2d (summarized in the *Lancet* for July 1st from a report in the *Deutsche Medizinische Wochenschrift*, 21-23).—After a few words of welcome by H. E. General von Beseler, Governor of Warsaw, the head of the German Army Medical Service, Professor von Schjerning, gave an interesting survey of its organization. There were, he said, more than 24,000 doctors in the service of the army, of whom 16,000 were actively employed at the front. Beside these, the Army Medical Service included 3,000 doctors employed in Red Cross work, 400 surgeon dentists, 1,800 pharmacists, and 92,000 men in the sanitary and ambulance departments. These were assisted by 72,000 voluntary nurses, male and female, at the base hospitals, and 22,000 in the war zone. Thousands of motor cars and vans were engaged in transporting the sick and wounded to the war hospitals, of which there were 238 in the whole country. There were also thousands of installations for the sterilization of water, for disinfection, and x ray examinations; twenty-six large mobile steam laundries were kept busy day and night for the military hospitals alone; and there were eighteen large disinfecting stations through which 100,000 men could be passed daily and their clothes dealt with. The central medical depot forwarded to the front daily wagon loads of medical preparations and surgical appliances. Surgeon General His, president of the congress, spoke of the successes hitherto attained in combating epidemics, asserting that "in spite of typhus and dysentery, spotted fever and cholera, the efficiency of the troops has never been impaired." Several scientific investigators had lost their lives during the war in combating these and other invisible enemies, among them Cornet, Prowazek, Lüthje, Jochmann, Römer, and Tilp. New diseases had been discovered, to one of which the name of "five day fever" had been given. Well known diseases, such as typhoid and dysentery, owing to previous inoculation, appeared only in modified form.

Army Hospital Trains.—Negotiations have about been completed by which the army medical corps is to have two hospital trains for service on the border. The trains are to be operated between the field hospitals and a base or general hospital at Grand Canyon, Colo., or some other desirable location. The trains will virtually be two field hospitals on wheels. They will have a capacity of seventy-five bed patients and seventy-five convalescents who are able to sit up. There will be ten cars in each train, consisting of kitchen car, dining car, operating room, four ward cars, two Pullman cars for convalescents, and one car for the personnel of the hospital corps. All the cars will be Pullmans and the ward cars will be stripped of their furnishings and equipped with hospital beds. Hospital equipment will be installed in the kitchen, dining, and operating room cars. With these two trains it is believed that all the sick on the border can be taken from the field hospital to the base hospital, where they can be treated under the most favorable conditions.

An extraordinary effort, according to the *Army and Navy Journal* for July 15, 1916, is being made by the Medical Corps of the Army to take care of the sanitary conditions under which the troops will be required to serve on the border. It is recognized that many of the National Guardsmen who are taken from comfortable homes in the north are not acclimated, and as a result will require special care. All of the regular army medical officers who can be spared have been ordered to the border. It is possible that some may be ordered from Honolulu and Panama to the border to assist in the extraordinary work that the corps will be called upon to do. In that event medical reserve corps officers will be sent to Honolulu and Panama.

Steps have been taken to furnish motor transportation for the field hospitals and ambulance companies on the border. One hundred and fifty motor cars have been purchased for this purpose and some of them have already been delivered. Seven motor trucks which will transport baggage will be issued to each field hospital, two for the personnel of the hospital and one for commanding officers. Ambulance companies will each be furnished with five ambulance motor cars, two for convalescents, two for quartermaster's supplies, and one for commanding officers. The automobiles for convalescents will be large cars of the type of the sightseeing cars used in large cities. They will be fitted out so as to provide every comfort for the patients. The organizations of the hospital trains and the motor transportation is in the hands of Captain Jones, who has recently reported for duty at the War Department.

Panic Makers.—Because its origin is mysterious and there is no known cure for it, and because the victims whom it destroys or maims usually are young children, the appearance of an epidemic of the disease called "infantile paralysis" in New York and the surrounding neighborhoods has excited great dread among parents throughout the country. It is unfortunate that health officers and newspapers, says *Collier's* for July 24th, have seen fit to issue exaggerated statements about the extent and progress of the disease. Their purpose is a valuable one, namely, to encourage vigilance on the part of the public, and it has spurred the authorities to a "clean-up campaign" which would be good at any time and would be better if carried on all the time and with system. But much of the usefulness of the publications has been offset by their frenzied manner which has literally scared people out of their wits. Trains going out of the cities are crowded with children whose frightened parents are carrying them away from comparatively healthful surroundings where there are thousands of good physicians, scores of great hospitals, and an abundance of medical supplies into small villages where there are few doctors, no trained nurses, and no hospitals, and only the scantiest provision for taking care of the sick. It would not be surprising if the herding of thousands of children in dirty day coaches at this time of year, without proper clothing or nourishment, brought about as many deaths as the disease from which their parents are fleeing. Health officers, above all others, should keep their heads and soberly spread the truth about the epidemic. There may be occasion for alarm, but there is no reason for panic. Infantile paralysis is not strictly a disease of larger cities. Some severe epidemics in the past have occurred in small suburban communities when the neighboring cities have hardly been touched. It would be disgraceful if the scare should result in the establishment of senseless quarantines which are the first resort of numskull local authorities when confronted by an epidemic. Some of us are old enough to remember the quarantine against yellow fever. They probably caused as many deaths, through exposure and hunger and consequent maladies, and they certainly caused as much suffering as the disease itself.

Precautions in Handling Cases of Poliomyelitis.—Dr. Beverley Robinson, of New York, recently sent the following suggestions to the *Evening Post:*

Too stringent rules at this time cause unnecessary alarm and great inconvenience. Moreover, they will not be obeyed and people will try to escape their restrictions. Imperative observances, which are personal, should be insisted upon:

1. Every nurse, or physician, caring for a case of infantile paralysis, should wear another garment in the sick room, which should be laid aside upon leaving it. If at all soiled by discharges from the patient, it should be put in boiling water for a while, with or without a disinfectant.

2. The hands of the physician should always be carefully washed the last thing before leaving the sick room. The same rule of washing the hands applies to the nurse, after any direct contact with the patient. All discharges from the patient should be burned, or disinfected. All utensils used by the patient should be washed and kept solely for the patient's use.

All covering and clothes, when soiled, should be put in boiling water.

There are some healthy carriers of infantile paralysis, even with these simple precautions, but they are very few and practically are negligible.

Infantile paralysis does not necessarily follow routes of travel and is not carried except in rare instances by a third person.

Therefore, if a child, or adult, is not actually ill with the disease and has not been with an affected patient, it is questionable, with the precautions insisted upon by me being adhered to, whether he should be interdicted from leaving home and securing good air, exercise, and health. Infantile paralysis may strike anywhere, even in isolated regions and children in perfect health.

Why then continue to spread wrong, foolish alarm, when by so doing one adds a great deal to human suffering and benefits no one?

Collectanea

Mobile Red Cross Base Hospitals.—The full list of twenty-five Red Cross mobile base hospitals under the charge of as skilled surgeons and nurses as our country affords has been made public by Colonel Jefferson R. Kean, Medical Corps, U. S. A., director general of the Military Relief of the American Red Cross. This list not only names the "mother" hospitals and their locations, but in most instances the directors and assistants of the base hospitals, each of which is organized or is being organized at an initial cost of $25,000. Colonel Kean also mentions two field columns or ambulance companies. The organizing of these hospitals, which, in war time, would pass under the immediate authority of the War Department and be transported to the base of military operations as they were needed, is considered a piece of war relief preparedness along scientific and constructive lines, and is based in part on the lessons of the European war. The nucleus for the directing personnel of each base hospital is selected from the staff of a big existing civil hospital and when that personnel is transported, on the outbreak of war, to the base of military operations, they continue at their respective posts, working in the same teamlike fashion they employed in civil capacities. Connecting the evacuation or transfer hospitals of the army with the base hospitals of the Red Cross are the field columns, two of which are being perfected at an expense of $15,555 each.

The director general made this statement concerning the base hospitals and field columns:

The medical officers attached to regiments, together with those manning the field hospitals and evacuation hospitals, constitute the medical service of the front. These field and evacuation hospitals would, in the opinion of our readers, scarcely deserve the name of hospitals, since they are marching units and have to be provided with only the simplest and most Spartan equipment. Their furniture is bed sacks, filled with hay and laid on the ground, or camp cots. There are shelter places where the wounded are received, fed, and protected from the weather on their way to the rear. The service of the front is therefore the special obligation of the medical officers of the army and of the National Guard, and the Red Cross is not permitted to share it.

The next zone, however, which is called the zone of the line of communications and base, is one in which the Red Cross will provide the greater part of service, as the number of medical officers in the army medical corps and connected with the National Guard is quite inadequate to provide such a service. The hospitals provided by the Red Cross, because they are situated at the military base, are called base hospitals. They are of great importance, because they are the first real hospitals provided with beds, mattresses, sheets, and trained nurses which the wounded soldier finds on his journey to the rear.

The base hospitals will receive regular, volunteer, and National Guardsman alike, and so every soldier whose duty brings him within range of hostile bullets has reason to take a keen, personal interest in the knowledge that in these hospitals is being now enrolled the most distinguished talent in the medical profession in this country.

Each division of troops requires at least one base hospital. It is equipped to receive 500 patients. Its professional staff consists of twenty-three physicians and surgeons, two dental surgeons, a chaplain, and fifty trained nurses. To assist the latter are enrolled twenty-five volunteer nurses' aids. The enlisted personnel numbers 153, while authority is given for the employment of about fifteen civilians.

The naval base hospitals, of which several are now in course of organization, are of about one half the size of the army hospitals. The medical equipment of one of the army base hospitals is estimated to cost about $25,000, and of a naval base hospital about $15,000.

This equipment should be purchased in time of peace and kept in store by the government, as, if properly stored, very few of the articles suffer much deterioration, while if the purchase is put off until time of war it is only with great delay and difficulty that it can be secured. To avoid this delay and to render the units promptly fit for service, many of the Red Cross chapters in cities where base hospital units are being organized have raised money to purchase it.

It was anticipated that arrangements could easily be made for the storage of this equipment service on government reservations, but in this expectation the Red Cross has been disappointed, and most of the chapters now find that they must make further appeal to individual patriotism and generosity to obtain a storage place.

The great advantage of organizing those units in connection with large civil hospitals is that in this way is secured a personnel which know each other and which are accustomed to work together so that team work and good organization are possible at the outset.

Collectanea

Clean Hands.—Disease germs lead a hand to mouth existence. If the human race would learn to keep the unwashed hand away from the mouth, many human diseases would be greatly diminished. We handle infectious matter more or less constantly and we continually carry the hands to the mouth. If the hand has recently been in contact with infectious matter the germs of disease may in this way be introduced into the body. Many persons wet their fingers with saliva before counting money, turning the pages of a book, or performing similar acts. In this case the process is reversed, the infection being carried to the object handled, there to await carriage to the mouth of some other careless person. In view of these facts the United States Public Health Service has formulated the following simple rules of personal hygiene and recommends their adoption by every person in the United States:

Wash the hands immediately before eating, before handling, preparing, or serving food, after using the toilet, after attending the sick, and after handling anything dirty.

Fraudulent Infantile Paralysis "Cures."—Officials of the Department of Agriculture charged with the enforcement of the Food and Drugs Act expect that the outbreak of infantile paralysis will tempt unscrupulous persons to offer for sale so called cures or remedies. They have issued special instructions to the food and drug inspectors to be particularly alert for interstate shipments or importations of medicines, the makers of which allege that they will cure or alleviate the disease, for which, at the present time, no medicinal cure is known. The officials also warn the public that any preparation put on the market and offered for sale as being effective for the treatment of infantile paralysis should be looked upon with extreme suspicion. Inspectors, accordingly, have been instructed to regard as suspicious, and to collect samples of all medicines in interstate commerce for which such claims are made. Makers of such fraudulent remedies will be vigorously prosecuted whenever the evidence warrants action under the Sherley Amendment to the Food and Drugs Act. So called remedies for infantile paralysis which are offered for import into the country will be denied entry.

The food and drugs officials are particularly watchful in this instance, because it has been noted in the past that whenever a serious epidemic exists, unscrupulous dealers prey upon the fear or ignorance of the public by flooding the market with worthless, hastily prepared concoctions, for which they claim curative properties which have no foundation whatever in fact. In the present instance, inspectors already have discovered shipments of a few such mixtures.

The department will do everything it can under Federal law to protect that portion of the public which is extremely credulous in times of panic and which grasps at anything which promises protection or relief. The sale of such products at this time, the officials point out, is particularly threatening to the public health because many persons, relying on the false statements of impostors, neglect to secure competent medical advice. As a result, not only is the safety of the patient endangered, but in the absence of proper sanitary precautions the likelihood of contagion is greatly increased.

It must be understood, however, that the Federal Food and Drugs Act applies only to products which are shipped in interstate commerce, that is, from one State to another, or which are offered for import or export, or which are manufactured or sold within a Territory or the District of Columbia. Products which are made and consumed wholly within a single State are subject only to such State laws as may apply and are under the control only of State health officials. The Federal law does not apply, for instance, to patent medicines made within the State of New York and sold in New York city. Persons buying or using a "remedy" made in their own State, therefore, must rely on the protection accorded them by their local health authorities.

Collectanea

Medical Corps Work on the Border.—Col. H. P. Birmingham, Acting Surgeon General, U. S. A., has sent the following memorandum to the Secretary of War: The Medical Department has supplied every need and request from the Southern Department. In addition to the various small hospitals at minor posts along the border we have established base hospitals at Fort Sam Houston and Fort Bliss, Texas. Base hospitals have also been authorized and are now being completed, supplied with personnel and equipment, at Brownsville, Eagle Pass, Laredo, Nogales, and Fort Crockett. The hospital at Fort Crockett is not in process of organization. Should it be necessary to establish this hospital, it will occupy the building of the post. In addition, there are hospitals at Forts Huachuca, Clark, McIntosh, Columbus, Camp Douglas, Marfa, Del Rio, and Deming. There are also seven field hospitals with the troops on the border, each with a capacity of 216 beds. This does not include the field hospitals of the organized militia now on the border. Field hospitals, while mobile hospitals, are always available to take care of the sick with troops until they can be evacuated to base hospitals. The Government has expended large sums of money constructing new hospitals and increasing the bed capacity of the hospitals already built. The Southern Department has at its disposal, in addition to the money already expended on hospitals, $300,000 to be used at the discretion of the department commander. In addition, the department has organized and is now having completed a hospital train for the transportation of the sick and wounded from the border stations to the base hospitals mentioned above.

The Army at this time has established general hospitals at the Presidio of San Francisco, Cal., with a maximum capacity of 953 beds; at the Army and Navy General Hospital, Hot Springs, Ark., 600 beds; and at Walter Reed General Hospital, Takoma Park, D. C., 320 beds. The department has completed plans for the establishment of general hospitals at Fort McPherson Ga.; Fort Sheridan, Ill.; Fort Douglas, Utah; Fort Oglethorpe, Ga.; and Fort Benjamin Harrison, Ind., should conditions warrant. These hospitals will have a capacity of from 500 to 1,000 beds. Plans have been completed for disinfecting trains in case it is necessary to enter Mexico, for the purpose of disinfecting clothing of the soldiers in order that they may be protected against typhus fever. All soldiers on the border have been vaccinated against smallpox and typhoid fever. Medical supplies are on hand sufficient for the needs of the army now in the field or under orders for the border. Attention is invited to the fact that for approximately five years the greater part of the regular army in the United States has been upon the Mexican border; the health conditions of the troops have at all times been excellent, and they have been and are now free from the usual camp diseases.

I believe the best interests of the Government can be served by announcing through the press bureau that the Government is not at this time in need of such committees as the American Committee for the Maintenance of the Border Hospital, Brownsville, Texas, and that appeals such as that filed by Mrs. Harriman convey a false impression and tend to create a feeling of insecurity and distrust in the minds of the people of the Government's ability to care for its soldiers. Contributions such as requested in the letter of Mrs. Harriman are absolutely unnecessary and the activities of such organizations should, especially at this time, be discouraged by the Government.

Progress of the American Red Cross Society.—Announcement is made that during the six months ending July 31, 1916, the membership of the American Red Cross Society increased from about 27,000 to about 210,000, an increase of nearly 800 per cent., and the number of Red Cross Chapters organized throughout the country increased from 110 to 199. During that time the personnel required for twenty-five base hospitals of 500 beds each for the United States Army has been selected and enrolled from among the staff of twenty-five of the largest hospitals of the country; several naval base hospitals, which are about half the size of the army base hospitals, are now being organized; funds for the purchase of equipment of sixteen of the twenty-five army base hospitals, costing $25,000 each, have been subscribed, and the purchase of the material for these base hospital units has been begun and the equipment as purchased is being stored, so as to be ready for immediate use in case of need. In addition to this organization of base hospital units, the personnel required for two field columns for transferring the sick and wounded from the transfer hospitals of the regular army medical service to the Red Cross base hospitals, has been selected and enrolled from among the staff of two important hospitals of the country, and $10,000 toward the purchase of the equipment for one of these field columns has been subscribed.

Plague.—The bubonic plague of today is identical with the black death of the Middle Ages. Primarily a disease of rodents caused by a short dumbbell shaped microscopic vegetable, the pest bacillus, it occurs in man in three forms; the pneumonic, which has a death rate of almost 100 per cent.; the septicemic, which is nearly as fatal; and the bubonic, in which even with the most modern methods of treatment the mortality is about fifty per cent. It is a disease of commerce, spreading around the globe in the body of the shipborne rat. It is estimated that every case of human plague costs the municipality in which it occurs at least $7,500. This does not take into account the enormous loss due to disastrous quarantines and the commercial paralysis which the fear of the disease so frequently produces.

The disease is now treated by a serum discovered through the genius of Yersin. This is used in much the same way as is diphtheria antitoxin. Plague is transferred from the sick rodent to the well man by fleas. The sick rat has enormous numbers of plague bacilli in its blood. The blood is taken by the flea, which, leaving the sick rat, seeks refuge and sustenance on the body of a human being to whom it transfers the infection.

Since plague is a disease of rodents and since it is carried from sick rodents to well men by rodent fleas, safety from the disease lies in the exclusion of rodents not only from the habitation of man but also from the ports and cities of the world. Those who dwell in ratproof surroundings take no plague. Not only should man dwell in ratproof surroundings, but he should also live in ratfree sourroundings. The day is past when the rodent served a useful purpose as the unpaid city scavenger. Rats will not come where there is no food for them. Municipal cleanliness may be regarded as a partial insurance against plague. The prayer that no plague come nigh our dwelling is best answered, however, by ratproofing the habitations of man. Modern sanitary science has evolved a simple and efficient weapon against the pestilence which walketh in darkness and striketh at noonady, and the U. S. Public Health Service has put this knowledge into practical operation and thus speedily eradicated plague wherever it has appeared in the United States.

Experienced Nurses to Be Sent to the Mexican Border.—In response to a request from the surgeon general of the United States Army, dated August 14th, that the names of 100 Red Cross nurses willing to be assigned to active duty on the Mexican border be furnished the War Department, Miss Jane A. Delano, chairman of the National Committee on Red Cross Nursing Service, has sent fifty-five of her expert, enrolled Red Cross nurses hurrying to our southwestern States to assist the United States Army nursing corps in alleviating the suffering of our armed forces who are policing the southern frontier against raids by marauding Mexican bandits.

Included in this group of Red Cross nurses are a number who have already shown their ability and heroism in bygone Red Cross accomplishments.

Miss Nell Floss Steel, of Columbus, Ohio, was a member of one of our hospital units in Serbia. The results attained by those units will never be forgotten.

Miss Antoinette Alschier, of the Dallas, Tex., detachment, who, in 1915, was assigned, along with several other nurses, to Brownsville, Tex., to care for sick and wounded Mexicans from across the Rio Grande, gave invaluable service in ameliorating the misery of the injured peons.

Miss Margaret McGary, of the Washington group detailed to Douglas, Ariz., has seen extensive service with our American Red Cross unit in Kief, Russia, and this experience will be of great value in her work among our soldiers.

Included in the nurses now selected for duty by Miss Delano are Misses Lulu T. Lloyd and Nannie Hardy, both of Washington, D. C., who were at Vera Cruz with the Army Nurse Corps during the occupation by the United States forces in 1914.

Miss Margaret H. Patterson, of Birmingham, Ala., and Miss Harriet P. Hankins, of Washington, D. C., have also had valuable experience in European hospitals during the present war.

The following tabulation gives the points from which these nurses have been sent, the number sent from each city, and their destination:

From	To	No.
Columbus, O.	Eagle Pass, Tex.	10
Birmingham, Ala.	Fort Sam Houston, San Antonio, Tex.	8
Norfolk, Va.	Brownsville, Tex.	2
Omaha, Neb.	Brownsville, Tex.	1
Washington, D. C.	Fort Sam Houston, San Antonio, Tex.	12
Washington, D. C.	Douglas, Ariz.	6
New York City, N. Y.	Fort Sam Houston, San Antonio, Tex.	2
San Antonio, Tex.	Fort Sam Houston, San Antonio, Tex.	2
Dallas, Tex.	Fort Sam Houston, San Antonio, Tex.	6
Cleveland, O.	Fort Bliss, El Paso, Tex.	2
Atlanta, Ga.	Laredo, Tex.	4

Additional groups of nurses, organized and ready for immediate departure, are now awaiting orders from the War Department in Portland, Ore., Denver, Colo., New Orleans, La., New Jersey, and Springfield, Mo. The American Red Cross has at its command an unexcelled nursing corps of over 7,000 graduate nurses, who are pledged for service in the event of war. By special authorization of the surgeon general, each of the twenty-five Red Cross base hospital units, organized by Colonel Jefferson R. Kean, Medical Corps, U. S. A., director general of military relief, has been requested to designate from its Red Cross personnel two nurses for service on the border, believing that this will greatly increase the efficiency of these units should they be needed for active duty.

Mortality from Heart Disease.—The causes of the large number of deaths resulting from chronic heart diseases have heretofore been but little considered as the subject of administrative control by health authorities. In this city, at the present time, according to the *Weekly Bulletin* of the Department of Health of the City of New York for September 2, 1916, over 10,000 deaths are reported annually to be due to organic heart diseases. It is probable that the apparent indifference of health administrators to the problem presented by this large number of deaths is owing largely to the fact that the deaths are in the higher age groups; thus in over 86,000 deaths occurring in the United States registration area in 1912 the age grouping was as follows:

DEATHS ARRANGED BY AGE GROUPS (1912).

Under 10 years	1,826
10 to 19 years	2,071
20 to 29 years	2,948
30 to 39 years	4,922
40 to 49 years	7,991
50 to 59 years	12,484
60 to 69 years	20,553
70 to 79 years	2,218
80 to 89 years	9,951
90 to 99 years	1,086
100 years	48
Unknown	101
Total	86,179

This age grouping, however, is misleading, for it gives no true picture of the age distribution of heart diseases in the community. A much better picture can be gained by noting age incidence of cases of heart diseases observed in hospitals. Such a study shows a large proportion of cases in all the age groups beginning with ten years of age. The following table may be cited. It relates to over 1,300 cases treated in a large hospital in Glasgow:

HOSPITAL CASES (GLASGOW) ARRANGED BY AGE.

	Organic Heart.
Under 10 years	20
10 to 20 years	221
20 to 30 years	264
30 to 40 years	274
40 to 50 years	257
50 to 60 years	186
Over 60 years	124
Total,	1,346

The physical examination conducted by the Bureau of Child Hygiene indicate that approximately 15,000 school children suffered from organic diseases of the heart. It is clear, therefore, that the enormous prevalence of heart diseases in the community constitutes a public health problem of the first magnitude. A review of these facts led to the organization of an association for the prevention and relief of heart disease. In a report just made by the executive committee the opinion is expressed that the prevention of heart diseases depends largely upon a study of the causes of the condition. These causes may be grouped under the headings, Infectious Diseases, Intoxication, and Improper Methods of Living. Of these the infectious diseases seem to offer the most immediate point of attack; and of the group of infectious diseases thus resulting from the so called rheumatics seem to be the most numerous.

The program of the Association for the Prevention and Relief of Heart Diseases embraces the following:

1. *To gather pertinent data* from many sources and to arrange it for general use and practical application to the purposes set forth.

2. The office of the association is to serve as a central cardiac *information bureau.*

3. To help in *coordinating* the various efforts in this field—as made by health department, school examiners, cardiac classes, dispensaries, special investigators, trade school for cardiacs, etc.

4. To organize cardiac *convalescence,* to provide larger opportunities in existing institutions, through assurance of better selections of patients, better treatment, etc. (especially for youth). Specialized cardiac convalescence is also a problem.

5. To help to establish more cardiac classes in appropriate districts, and to extend and correlate their efforts.

6. To study and develop *occupations* for cardiacs, in standard trades and situations, as well as in special lines as already begun. To take constructive interest in workman's compensation and like problems affecting cardiacs.

7. To work constantly for the *prevention* of heart disease, through the power of accumulated information effectively presented, and the increasing application of recognized means (such as adequate facilities for throat and dental treatment, particularly in youths, etc.)

8. To encourage the setting up of branch (or like) associations elsewhere.

Eight special cardiac classes having a uniform working plan for the division and classification of cases have already been established. Seven of these are in Manhattan and one is in Brooklyn.

The Health of Our Troops.—Judging from the reports issued by the War Department up to the present as to the health of the U. S. troops in the field, it may be safely said that sanitary conditions have been vastly improved in our army since the Spanish-American war, proudly remarks the *Army and Navy Journal* for September 2, 1916. And it may also be said that the Medical Corps has kept abreast of the advance of medical knowledge in the last eighteen years to the betterment of the condition of the officers and men of the U. S. Army and of the National Guard.

While it is true that absolute comparisons cannot be made as yet between the health statistics of the present mobilization and those of the campaign of 1898, it is possible to make relative comparisons; and these are all to the advantage of this year's work in the field. According to Surgeon General Sternberg's report for the months of May-September, 1898, the tabulation represented a strength of 167,168 men, while this year we have a total of 139,222 men in the field, according to the statistics issued by the War Department on August 5th. That is not so great a difference in the gross numbers of men in the two mobilizations as seriously to affect the percentages; while in the present mobilization there is almost a total absence of the mention of such diseases as yellow fever, typhoid, malarial fever, with the consequent "weakness, prostrations, anemia, and emaciation of the troops," resulting from these fevers, which brought about the scandalous and untruthful newspaper stories of "starvation" at Camp Wyckoff.

In the months of the Spanish war covered by General Sternberg's report there were 1,715 deaths among the troops, of which 640 were from typhoid fever alone. Complete statistics of the deaths in the National Guard since the troops were mobilized have not been issued as yet, but the partial reports show an extremely low death and sickness rate among the men of the guard, the week of August 5th giving only two deaths in the guard organizations with a sick rate of 1.14 per cent. This was for 98,500 men. In the same report the regulars had six deaths for the week and a sickness percentage of 2.45, these figures being for the 40,722 men on the border and in Mexico. The weekly health report from the southern department for the week ending August 19th shows the same general proportion, the proportion of sick in the National Guard being 1.17 per cent. with three deaths and of the regulars 2.02, with two deaths. The fact that the sick rate among the regulars is higher than among the men of the National Guard is only a repetition of the experience of 1898, as indicated by General Sternberg's tables, which show a death rate of 3.62 among the volunteers in August of that year, while among the regulars the death rate was 5.83, the whole experience of the Santiago campaign giving the regulars a higher rate than that of the National Guard.

In view of the fact that there has not been a single case of typhoid fever and only six deaths from disease among the regulars who entered Mexico five months ago, General Pershing said on August 22d, commenting on the health report: "This is a remarkable record for an expedition serving in this sort of a country with nothing but field equipment. It probably is as low a record as any similar expedition ever has set and shows the wonderful strides made along sanitary lines within the last few years and the high efficiency of the sanitary department. It also shows the high appreciation of sanitary regulation by line officers, who have been held to a strict account for violations of these commands. Only once during the life of the expedition has there been what threatened to become an epidemic. This occurred recently at a camp south of headquarters, where the water caused a number of cases of amebic dysentery. When the sick rate climbed to five per cent. the chief surgeon and his entire corps were sent from headquarters. A quick and exhaustive study of camp conditions was made and measures taken which soon reduced the rate to 1.7 per cent. The chief means used in curing this epidemic was the chlorination bag. This destroyed the organisms in the water which caused the disease. At one time there were 125 cases at the camp mentioned. There are now thirteen. From available data it appears that the sick rate in the expedition is less than half that in the United States."

General Sternberg made the criticism in his Spanish war report that the prevalence of sickness in the camps was caused by the "manner of occupation" rather than by the sites. It would seem that there had been as much improvement in this respect as in all others under the direction of the army, an excellent illustration of which is to be found at the Tobyhanna, Pa., camp, at which there never have been more than five patients at once in the hospital.

Interstate and Intrastate Control of Poliomyelitis (*Public Health Reports,* for September 1, 1916).—The Conference of State and Territorial health authorities with the United States Public Health Service convened for the consideration of the prevention of the spread of poliomyelitis, at Washington, D. C., August 17 and 18, 1916, adopted the following committee report:

I. It is the sense of this committee that the first step proper to be taken by a State health authority, believing its territory to be in danger of an invasion by poliomyelitis from another State or part of a State, is to call attention to the situation and to request the United States Public Health Service to take whatever steps are necessary to prevent interstate spread.

II. The steps to be taken by the United States Public Health Service are believed to be:

1. Investigation of the infected area.

2. Notification concerning the removal of persons sixteen years of age or under from an infected area to a named point of destination in another State, said notification to be addressed to the State health authority of the State of destination.

3. The forms of notification and of health certification and of permits to travel should include the following information and specifications with such additional information and specifications as the United States Public Health Service deems necessary: Identification of each traveler, the exact location of present or usual residence, and record of premises as to freedom from poliomyelitis during the preceding three months; or as to latest date of infection if less than three months; or as to renovation or cleansing of premises after infection.

4. Permits to travel shall be void unless the journey shall begin within twenty-four hours after issue of the permit.

5. Single permits shall not be issued for several persons, except for family or household groups coming from the same domicile.

6. The collection of fees, by health officials, from applicants for permits, whether resident or nonresident, should not be permitted.

7. The certificates of private physicians will not alone be a sufficient basis for the issue of a permit to travel. Permits for interstate travel will be based on medical inspection.

8. Permits for interstate travel should be signed by an officer of the United States Public Health Service, or by the State health officer, or by an officer authorized by the State health authority.

III. The committee disapproves quarantine by one State against another State or quarantine by one community against another community in the same State. It is believed that the Federal Government, through the United States Public Health Service, can perform all the duties of notification and certification required in interstate relations in case of unusual prevalence of poliomyelitis, and that State health authorities can and should perform like services as between communities in the same State during unusual prevalence of poliomyelitis.

IV. It is recommended that all cases should be reported immediately to the local health authorities and to the State health authorities, and that State health authorities make weekly reports to the United States Public Health Service. The United States Public Health Service is asked to furnish general reports weekly.

V. It is recommended that all persons sixteen years old or under, with a clean bill of health, and removing from an infected area or district to another locality, should be kept under medical observation daily for two weeks.

VI. It is believed that the period of isolation should be not less than six weeks from onset.

VII. The isolation should be stringent of the sick person with attendant or attendants, in a properly screened room or rooms, with disinfection at the bedside of all bodily excretions. Removal of patients to a hospital is greatly to be preferred to isolation in a private house.

VIII. In case of death from poliomyelitis the funeral should be strictly private.

IX. Wherever poliomyelitis is unusually prevalent, assemblages of children in public places should be prohibited.

X. During the unusual prevalence of poliomyelitis, schools should not be opened without thorough medical supervision. When schools are opened, beginning should be made with high schools, and proceed to lower age groups no more rapidly than complete medical examinations can be made.

XI. Because of the existence of unknown carriers, and because the infectious virus is present in the body discharges of such persons, therefore all measures to prevent contamination by human excreta or other bodily discharges, the suppression of the fly nuisance, prohibition of the common drinking cup, and a general educational compaign, are strongly urged.

XII. Common carriers should instruct their agents and ticket sellers that travelers with children of sixteen years or under must be provided with a health certificate. Common carriers are to be notified of the area and prevalence of the infection and at what points certificates must be displayed before permitting the travel of children of sixteen years of age or under.

XIII. The epidemic prevalence of poliomyelitis in certain States at this time indicates a probability of epidemic prevalence next year in States not gravely affected at the present time.

Collectanea

Value of the Lyster Field Water Bag.—The field water bag designed by Major William J. L. Lyster, Medical Corps, U. S. A., now serving as an observer in the European war, is proving of inestimable value to the forces on the Mexican border, says the *Army and Navy Journal* for August 26, 1916. With it all of the water consumed by the forces in the field is sterilized and the officers are able to supervise the filling of a soldier's canteen. The appliance consists of a canvas bag of special woven flax, which can be suspended on any convenient support, and has a capacity of 330 pounds of water. The bag is not intended for transporting water, but to provide a stationary water tank which can be carried by the troops. The empty bag weighs from seven to seven and a half pounds and folds into a convenient package, which can be carried by the soldier in the infantry pack when other transportation is wanting. Two of these field water bags are issued to each company, and it has been found that they have sufficient capacity to supply drinking water for such a force. After the bag is suspended and filled with water it is sterilized by the addition of a small amount of hydrochloride of lime. This is carried in measured doses sealed in glass tubes. A package of sixty of these tubes weighs ten ounces and forms a package about as large as a pound of roasted coffee. With these tubes all typhoid fever and other bacteria can be killed in the bag of water. The army is now being served with the purest water owing to the simple device of Major Lyster.

Condition of Camp Whitman, N. Y.—In the opinion of Lieutenant Colonel Henry Harlow Brooks, chief surgeon on the staff of Brevet Major General Daniel Appleton, commanding the 2d Division, N. G. N. Y., the isolated location of Camp Whitman, Green Haven, N. Y., from a sanitary standpoint gives the camp very great advantage. It is not likely to be littered up with various refuse and the remains of eatables left by visitors. It has very desirable climatic conditions, remarks the *Army and Navy Journal* for September 16, 1916, and contagious diseases have been few. Doctor Brooks, who is known as an officer of sound practical views and a keen observer, notes these points and many others in a report to General Appleton. He was ordered to duty at Camp Whitman after the main body of troops had departed for Texas. Doctor Brooks states that the water problem, which at first was a serious one, was finally overcome, and there is now an ample supply of good water. He also states that the site of the camp verifies the judgment of those who selected it.

Perhaps the most important feature of the report is that relating to bacteriology, of which Doctor Brooks says:

> Experience, notably in this camp, has shown the imperative necessity in every large camp of an expert bacteriologist to conduct examinations of water, make cultures from suspicious disease conditions, and especially to make such tests as may be necessary to determine specific infection, such as dysentery, typhoid, diphtheria, malaria, and the like. This work during the encampment has been efficiently performed by Doctor Van Winkle, generously detailed for that purpose by Dr. Augustus Wadsworth, of the State Research Laboratories. For thorough cooperation in these matters it is, however, necessary that familiarity with military methods and procedure as well as objects should exist, and this is very difficult when such work is performed by civilian physicians.
>
> There are several men now serving as medical officers in the N. G. N. Y. who are perfectly competent to do such work. A suitable equipment is obtainable from the U. S. Army supply lists, and there is no reason whatever why this work should not be added to that of our corps, thereby greatly increasing its efficiency and at the same time adding to the attractiveness of the service for a very desirable class of physicians, who would be thus greatly increased in numbers. In the armies abroad this work is entirely in charge of the medical corps, and there is no reason why this should not also pertain in our Service.

Doctor Brooks praises Major A. V. Wadhams, Medical Corps, U. S. A., for his hygienic work at Camp Whitman; and Major Daniel R. Lucas, Medical Corps, N. G. N. Y., camp surgeon, and Lieutenant Col. A. F. Townsend, Q. M. C., are also praised for their work. The fact that Major General Appleton and Adjutant General Stotesbury granted 100 per cent. of requests made to them by the medical department for supplies, etc., is given by Doctor Brooks as the reason why Camp Whitman has been remarkable for its small percentage of sick men.

The Mayor of New York to Its Citizens.—The Committee on Arrangements for the Dinner of the Committee of One Hundred and Seven has issued a printed copy of Mayor Mitchel's report to them on what was accomplished by his administration during 1915. Concerning the department of health, the mayor reported as follows:

In spite of a slightly decreased appropriation for 1916, great improvements have been effected. We have begun to control the dangerous traffic in patent medicines. We are developing health centres which gather together under single supervision the different health activities, thus preventing conflict and overlapping. The entire borough of Queens has been put under this plan, and we shall gradually extend these health units until the entire city is served by them, carrying out the policies of the department, but guided by local officials who thoroughly understand the needs of the particular sections of the city which they serve. A special division of industrial hygiene has been organized, seeking first to ascertain and then by cooperation with employers and employees to diminish the special health risks involved in certain occupations. The supervision of overcrowding in subways and street cars has been continued with as good effect as present transportation facilities will permit. The attempt by the legislature of 1916 to take this power away from our health department was vigorously resisted and defeated.

We have reversed the traditional policy of waiting for complaints about unsanitary conditions. We are now making sanitary surveys on our own initiative and dealing vigorously with unsanitary conditions found. The improvement in public health is largely a question of public education. We have strengthened the educational division of the department, which is every day carrying on an expanding campaign of education in public and personal hygiene. The pasteurization of all milk has been required and there is a more complete inspection of all places where food is handled. Five new municipal milk stations have been established and seven more by private funds, to which latter the department supplies nurses and doctors.

The campaign against the mosquito nuisance has been extended.

Typhoid Carriers.—The Bureau of Preventable Diseases, says the *Weekly Bulletin* of the Department of Health of the City of New York for August 26, 1916, has now a list of thirty-five chronic typhoid carriers. The list is a growing one. Search for the carrier in the case has become a very important part of epidemiological investigation in typhoid fever. There are the more or less obvious contact infections in which one active case follows another, and also the secondary infections resulting from the precocious carrier, discharging the typhoid bacilli before he has himself shown the clinical symptoms, and others from cases of "walking typhoid," and from the so called convalescent or temporary carrier. The last mentioned is especially important and constitutes a common source of typhoid infection. In view of this, more care than ever before is being taken about the termination of typhoid fever cases. The patient recovers, strength returns, and, wholly innocent of the harm he may be doing, he mingles again with family and friends, observing no precautions, having no knowledge of the fact that he may be at least a temporary carrier of the infection. Physicians are urged to instruct their patients on this point—to warn them that "precautions" must be kept up for a long time.

Beside all this, the investigator must never forget the chronic form in which the carrier state is prolonged for months and years, with constant or intermittent excretion of the germs, and which appears to be dependent upon the bacillus having gained a secure foothold along the biliary tract, or elsewhere. This is the point we are stressing in our present method of investigation. Has any one in the family, or in the house, or among servants, or among friends with whom the patient was in contact during a month prior to the onset of his illness, ever had typhoid fever? When the answer is yes, we endeavor to ascertain if the individual in question is a carrier. Cultures are made from stools and urine. The Widal test is tried. Even where the laboratory reports are negative, a series of typhoid fever cases occurring at varying intervals in some family, institution, or smaller community is strongly presumptive of the presence of a carrier. In the thirty-five cases referred to, however, the carrier state has been proved to exist by repeated positive fecal examinations. Again, there are doubtless many persons who have had typhoid fever at some time in their lives without recognition of the nature of their illness. Any one of these may be a carrier. This indicates the value of routine Widal tests in search of carriers—though it is to be remembered that the Widal reaction is sometimes negative even in chronic carriers.

Medical Care of the Native Alaskan.—The problem of caring for the natives of Alaska is among the most difficult matters which confront the government in its relations with the aboriginal tribes, says the October *Medical Sentinel.* There is no central point in Alaska, Seattle being the trading centre of the Territory. These people are scattered along a waterfront of more than 5,000 miles. They live in small villages. They are still influenced by the superstitions which have come down to them from the centuries. They hide, rather than seek relief for their ailments, believing that there is some divine retribution in misfortune.

Secretary Lane of the Interior Department, who personally knows every part of Alaska, has given tender consideration to the needs of the native Alaskan, and great improvement has taken place in the care of these people, especially during the past two years. Syphilis and tuberculosis, here as elsewhere, have wrought sad havoc with the primitive people. The editor of the *Medical Sentinel,* in a trip just completed in Alaska, was forcibly impressed by the special interest now being shown by the government in the medical side of care for the natives.

At Juneau, Dr. Douglas Brown, a recent arrival, is in charge of a splendid native hospital just completed by the Interior Department, which looks after fourteen near by villages. Doctor Brown serves under the Educational Division of the Interior Department, is a civil service employee and was for some years with Colonel Gorgas on the Panama Zone.

At Haines a special hospital is soon to be erected for tuberculosis cases, and soon a colony with every modern equipment will be in operation. In other portions of Alaska, seven or eight physicians have been put in charge of the medical Indian service, and three other small native hospitals are already maintained by the government in the territory. An attempt is now being made by Secretary Lane to employ teachers in the Educational Division, for stations where no doctors are situated, who are also trained nurses. These teachers have some special training for emergency medical work, receive a medical and surgical equipment of simple character and are provided with proper instructions for the service along medical lines. As fast as appropriations can be secured, district zones are being organized, comprising a neighborhood of native villages, for which a general hospital and a competent physician are supplied.

The insane native has the benefit of care outside of Alaska, where, in a milder climate, the percentage of recoveries is very large. The tuberculous insane live in a separate department, at Portland, Oregon, where they enjoy every qualification for modern treatment. The Educational Department in these more recent departures, seeks, among other things, to educate the natives as to the prevention of tuberculous infection; also as to the dangers of syphilis, its possible cure under appropriate treatment, thereby effecting the lowest possible evil to the living, as well as to the unborn progeny of the native races of Alaska.

Unloosing the Quacks.—According to the *Weekly Bulletin of the Health Department* for October 7, 1916, a newspaper dispatch from Albany has announced a decision by the Court of Appeals of grave concern to all who are interested in keeping the wolves from the lambs—in protecting unsophisticated laymen from unqualified pretenders to the healing art. The dispatch states:

> It (the Court) held that while the practice of healing by Christian scientists would come within the legal definition of medical practice, the statute specifically exempts those who in the treatment of bodily ills follow out the tenets of any religion. Christian science practitioners are protected by this exemption, according to the decision.
>
> The case was carried to the Court of Appeals by Willis Vernon Cole, a Christian scientist, who was convicted in New York in 1912 of practising medicine illegally and fined $100.
>
> The Court reversed the judgment of conviction and ordered a new trial.
>
> The action against Cole was instituted by the New York County Medical Society.

While the medical profession is engaged in increasing the requirements demanded of all who wish to begin the study of medicine, and in raising the standards of medical colleges and the exactions of qualifying examination, in order to secure better service to the public, there are some among the laity who are unwilling to see the practice of the healing art advance beyond the standards of superstition where the laying on of hands, the use of amulets, charms, signs, and magic phrases are relied upon to destroy the parasites of infectious disease in the sick and to frighten them from the well. Are such as who refuse to recognize that a typhoid infection, a smallpox eruption, or even a broken leg is anything more than a state of mind, to be allowed to pass in this State as qualified under the law to attend the sick?

May any scamp who wishes to turn healer for "easy money" claim immunity from the law by pretending that he has a divine mission to heal, that his practice is part of a religion, which he may easily invent to cloak his purpose?

Instead of four years at high school, a year or two at a general college, and a four year medical course, followed by an exacting State examination and perhaps by a year's service in a hospital, may one take thought overnight and hang out one's shingle in the morning, as a disciple of Christian science or as anything said to be a religion?

If this is to be so, and we are loath to believe it, it will be much harder upon the public, the lambs who will be exposed to the wolves, than upon the shepherd dogs (the qualified physicians) who endeavor faithfully to guard the flock!

Caring for Destitute Serbian Noncombatants.—An insight into gratifying civilian relief activities which are being directed in Serbia for the American Red Cross by Mr. Edward Stuart and Dr. Edward Ryan is given by two letters just received at Red Cross headquarters from Mr. Stuart in Belgrade, the captured former Serbian capital, dated August 28th and September 13th. Mr. Stuart first went to Europe for the American Red Cross early in 1915 as the head of a supplemental force of skilled American sanitarians, and participated in the suppression of the deadly typhus epidemic of that year, while Dr. Ryan piloted into Serbia by way of Greece some months prior to that the first detachment of American Red Cross surgeons and nurses which served in Belgrade, caring for both Serbian and Austrian wounded and typhus victims for over a year.

An Associated Press dispatch as late as October 9 said, owing to the inability of the American Red Cross relief commission to obtain further supplies from Rumania, the work directed by Mr. Stuart probably would be terminated with the exhaustion of the supplies on hand toward the end of November. The number of persons depending on the commission for relief of one kind or another was then given at 36,000. Approximately 3,180 tons of food, in addition to ten carloads of clothing, had been distributed. The American Red Cross, by means of relief materials, obtained in the United States and Rumania and contributed by the Swiss Government, and aided by Austrian military authorities, had succeeded in tiding the needy Serbians over the lean period of the year while the crops were growing. While starvation conditions had been relieved, there was still an urgent need for clothing, and Mr. Stuart hoped this want would be supplied from the United States.

The first of the two letters from Mr. Stuart above referred to was written just after Rumania had declared war upon Austria-Hungary. Rumania has been the source of large stores or relief supplies which Mr. Stuart has been purchasing for the American Red Cross not only for the relief work he is directing in Belgrade but for Doctor Ryan's party to the south. Prior to the declaration of war Mr. Stuart had procured across the Rumanian frontier 257.5 carloads of supplies, including eighty carloads of maize shipped from Bechet. He spoke of expecting also sixty carloads of maize which had been bought in Rumania by the Swiss Red Cross for the American Red Cross representatives to distribute. In his later letter he advises that these sixty carloads had arrived to augment the already large store and that forty-six carloads were being forwarded to Dr. Ryan in the interior. The addition of the Swiss shipment, Mr. Stuart reports, provides enough supplies to last until late in November.

Two distributing stations for food and a third for the distribution of clothing and shoes are being operated, but owing to the primitive milling facilities the ration per person per week for the destitute people of different nationalities was being limited to one kilo (about 2.20 pounds) per individual per week, and in the meantime every effort was being made to repair two large mills that were out of commission.

Mr. Stuart tells of having had a profitable conference with Mr. Otto T. Bannard, of New York, inspector general of foreign relief work for the American Red Cross in Vienna recently.

"The Public Welfare Department of the Government," advises Mr. Stuart, "has finally completed what is known as a People's Kitchen, but it will probably be some time before it is running to its full intended extent. The first object of this kitchen is to supply one meal a day to the inmates of the asylums in the city, the orphanage, the old people's home, the deaf and dumb institute and the nursery, in all about 200 persons. The funds to do this with must come from the profits of other operations of this department, such as a small moving picture show and the sale of illustrated postal cards, which amount to but very little. The Government gives no financial assistance, but the City Government supplies sufficient flour to make bread for the 200 at the present time, although when we first came to Belgrade the amount of flour was very inadequate. We have decided to assist this kitchen with supplies which are to be used exclusively for the asylums, records to be kept of the disposition of our supplies and the whole operation being always open to inspection by us. This has been agreed to by Oberlicutenant Lohar, the chief of this department, who is a very charitable minded man, and we have already given some supplies such as lard, salt pork, rice, beans and macaroni. Later it is intended by the lieutenant to supply soup once a day to all the school children in the city, in number about 1,500, but that has not yet been arranged. They expect to open the schools about the first of September."

"The distribution of clothing is progressing favorably and we have already given clothing to 10,000 people and have on hand sufficient for about 10,000 more," Mr. Stuart advises in the later letter.

The Need of Hospital Ships.—One of the many lessons learned by the Russian navy in the present war is the need of hospital ships, says the *Army and Navy Journal* for October 14, 1916. A writer in the London *Daily Mail* thus describes one of these vessels now with the Baltic fleet: "The operating room was especially ingenious. It would have been awkward to alter the vessel so completely (she is a requisitioned passenger steamer) as to make her the counterpart of a hospital on shore. In any case, it would be exceedingly difficult to keep an operating room on board ship as it should be kept, entirely free from dust and germs. This difficulty has been got over by enclosing a space sufficient for two surgeons to work at two operating tables with linen curtains which reach from ceiling to floor. The floor is of zinc, with a curb all around it. It can therefore be washed easily and quickly. I was shown how the severely wounded are hoisted on board out of smaller vessels in such a manner that the stretchers on which they lie do not lurch or sway about in mid air. The transference was carried out exceedingly well and quickly. Not more than a minute and a half was taken over each case. Then I saw also a most useful arrangement for saving badly wounded men from death by drowning. Great cages of rope and wire have been constructed (after a German design, the surgeon general told me) which can be lowered into the water and half submerged. In this there is room for many wounded to crawl and lie, while hundreds can cling to the outside."

Typhoid Carriers.—That intensive study of typhoid carriers is well worth while may be seen from the following data, observes the *Weekly Bulletin* of the Department of Health for August 26, 1916:

Prior to 1915 we knew of some half dozen chronic typhoid carriers in the city, including Typhoid Mary, who was "lost" for the time being. With her rediscovery in somewhat tragic circumstances, fresh impetus was given to the search for carriers. During 1915 five more were added to the list. Now, in the first half of 1916, twenty-two more have been discovered. In addition to search made incidental to the investigation of active cases, either sporadic or in outbreaks, the bureau is also conducting a systematic search for typhoid carriers in the routine examination of professional food handlers. It happens that none of our carriers was revealed by this method. Nevertheless, every food handler giving a positive Widal and a history of typhoid fever is subjected to bacteriological examination.

An analysis of the thirty-five cases shows some points of interest. Six patients are in one of the New York State hospitals for the insane in New York. Of those in ordinary life, the ages run as follows: Under ten years, one; ten to twenty years, one; twenty to thirty years, seven; thirty to forty years, two; forty to fifty years, seven; fifty to sixty years, seven; over sixty years, four. Nine are food handlers by occupation. This is a most serious consideration. They have been required to give up their accustomed means of livelihood. Of the nine, four were for a time confined in the health department hospitals. Three have since been released on finding other occupation. Another is an old man who has since retired from business. Another—comparatively young, with a wife and children to support—has been compelled to give up a lucrative position as a confectioner and accept employment at unskilled mechanical work, and requires charitable aid to supplement his income.

A woman keeping a little candy and ice cream store has, perforce, given up her occupation.

Another carrier kept a butcher store and has, for the time, given up work, at great financial sacrifice.

Another, apparently recovered, is engaged in a certain class of food handling, under close supervision.

A young man, who was a teacher in an institution, has been compelled to resign his position.

Others are married women, supported by their husbands; or, if single or widowed, support themselves by suitable work. Two are homeless and wandering about. One of the carriers is a little boy at school.

This presents the economic side of the typhoid carrier question, and is suggestive of the gravity of the situation.

The supervision of the chronic carrier has already become an important part of our work. In a recent number of the *Bulletin* we printed our Rules for Typhoid Carriers. Each carrier is visited from time to time. A journal is kept to record items of interest. From time to time stool specimens are examined.

In addition, a report is made to the United States Public Health Service and to the State Department of Health. This is looking toward the establishment of National and State registers of all chronic typhoid carriers.

A few of these chronic typhoid carriers are under treatment. This important matter is the subject of constant study, with at least theoretical promise and encouragement.

The Accuracy of Certified Causes of Death.—At the annual meeting of the American Public Health Association, held in Cincinnati on October 24th, says the *Weekly Bulletin* of the health department, the accuracy of certified causes of death was one of the important subjects considered. To the meeting was submitted the report of a special committee, of which Dr. Haven Emerson is chairman, appointed to consider the causes in question and their relation to mortality statistics and the International List of Causes of Death. This was appointed following the presentation of a paper, by Doctor Emerson, to the Section in Vital Statistics at the Rochester meeting, September 10, 1915, in which it was brought out that:

If the 189 titles of the international list are studied in the light of present day knowledge of clinical and pathological experience, it will appear that there is no plausible guarantee of accuracy in at least forty-one per cent. of the certificates as now presented to the registrar of records of the New York city health department.

In this forty-one per cent. we find 2,875 deaths in 1914 attributed to causes that can be accepted as reliable only after autopsy and 27,995 which are capable of verification by exact observations, as by chemical, bacteriological, and biological tests before death; but failing such specific proof, represent no reliable statement of death without autopsy.

Among the conclusions of the committee, as presented in *Public Health Reports,* for September 22d, are: That the following causes of death are not acceptable unless confirmed by a laboratory diagnosis disclosing the etiological factor: 3. Relapsing fever; 4, malaria; 14, dysentery; 21, glanders; 22, anthrax; 38, gonococcus infection; 53, leucemia; 106, ankylostomiasis; 107, intestinal parasites.

That the following causes of death require autopsies: 10. Influenza; 11, miliary fever; 23, rabies —without proof of bite by a rabid animal; 26, pellagra; 29, acute miliary tuberculosis—unless tubercles have been found in an accessible portion of the body (e. g., retina) during life; 31, abdominal tuberculosis—unless proof by an abdominal operation or presence of the tubercle bacillus is presented; 36, rickets; 37, syphilis—unless diagnosis was based on visible lesions or confirmed by specific test: 40, 41, 42, 45, cancer of various internal organs—unless seen at operation or otherwise visible; 53, Hodgkin's disease—unless accompanied with confirmatory record of microscopical examination of specimens removed from tumor during life; 54, anemia, chlorosis, unless confirmed by laboratory diagnosis before death; 61, simple meningitis, unless infecting organism had been demonstrated—title to be changed to "acute infectious meningitis"; 68, other forms of mental alienation; 69, epilepsy, unless death occurred in a witnessed attack and there was a confirmatory history; 77, pericarditis—unless secondary, or exudate had been obtained by paracentesis and examined; 102, ulcer of stomach—unless verified by operation; 103, other diseases of the stomach—unless verified by operation; 108, appendicitis and syphilis—unless verified by operation; 109, subtitle intestinal destruction—unless accessible for examination through body orifices or confirmed by operation; 115, other diseases of the liver; 116, diseases of the spleen—unless verified by operation; 117, simple peritonitis (nonpuerperal); 119, acute nephritis; 122, other diseases of the kidneys and annexa—unless operation was performed or after inquiry; 131, cysts and other tumors of the ovary—unless verified by operation; 154, senility; 164, poisoning by food—unless confirmed by supporting data; 187, ill defined organic disease; 188, sudden death.

Various changes in different classifications were also recommended and the addition of the following titles to the official list: Acute poliomyelitis, epidemic cerebrospinal meningitis, septic sore throat, diseases of the thymus gland, diseases of the parathyroid, diseases of the pituitary body, Hodgkin's disease, caisson disease, and some others. The elimination of the titles cholera nostras, mycoses, white swellings, disseminated tuberculosis, etc., was recommended.

The subject of this report, after consideration by the Section in Vital Statistics of the American Medical Association, will be submitted to the International Commission, charged with revision of the International List of Causes of Death, when it meets in 1919.

Tuberculosis Week.—December 3d to December 10th inclusive has been set aside as Tuberculosis Week in the United States. During this week an effort will be made to enlist the cooperation of every church, school, antituberculosis and public health organization, lodge, and workingmen's organization in the United States in an active effort to bring tuberculosis to the attention of the people. Three special feature days will be held during the week. December 6th will be National Medical Examination Day. On that day an effort will be made to get everybody, men, women, and children, sick or well, to be examined in order to find out if they have any defects or impairments of their bodies that need attention. If examination is not possible on December 6th, appointments will be made then for later examination. December 8th will be Children's Health Crusade Day. It is hoped at that time to launch a national organization of Modern Health Crusaders, an association of the children of the United States in the public schools, to fight against tuberculosis and for better health.

December 3d to 10th will be observed, according to the convenience of the churches, as Tuberculosis Day. A special sermon and a series of talking points for ministers and others have been prepared and will be ready for distribution in the near future. Last year over 150,000 organizations and institutions took part in the Tuberculosis Week celebration. It is expected that this year the number will be greatly increased.

Our Present Knowledge of Poliomyelitis.—The following authoritative statement, from the American Public Health Association, appears in the *Weekly Bulletin* of the Health Department for November 4, 1916:

At the recent annual convention of the American Public Health Association, held in Cincinnati during the week of October 23-28, a committee was appointed with instructions to prepare a report of "the present actual knowledge of the cause of poliomyelitis, the manner and agents by which it is spread, the best methods of treatment, and the best preventive methods." The report of this committee was presented at the closing session of the association and was unanimously adopted, with the recommendation that it be published as the authoritative statement of the association.

The specific cause of poliomyelitis is a microorganism, a so called virus, which may be positively identified at present only by its production of poliomyelitis in monkeys experimentally inoculated. Such experiments have shown this virus to be present not only in the nervous tissues and certain other organs of persons who have died of poliomyelitis, but also in the nose, mouth, and bowel discharges of patients suffering from the disease. It has been proved by similar experiments that healthy associates may harbor the virus in their noses and throats. These experiments, together with the fact that monkeys have been infected by direct application of the virus to the mucous membrane of the nose and by feeding of the virus, are strong evidence that in Nature infection may be directly spread from person to person.

Observations on the occurrence of the disease might seem at first thought to be inconsistent with this conception, since contact between recognized cases can seldom be traced. However, this may be adequately explained by the lack of means for detecting mild nonparalytic cases, and by the belief that healthy carriers of the virus and undetected cases are considerably more numerous than the frankly paralyzed.

Many facts, such as the seasonal incidence and rural prevalence of the disease, have seemed to indicate that some insect or animal host, as yet unrecognized, may be a necessary factor in the spread of poliomyelitis, but specific evidence to this effect is lacking, and the weight of present opinion inclines to the view that poliomyelitis is exclusively a human disease, and is spread by personal contact, whatever other causes may be found to contribute to its spread. By personal contact we mean to include all the usual opportunities, direct or indirect, immediate or intermediate, for the transference of body discharges from person to person, having in mind as a possibility that the infection may occur through contaminated food.

The incubation period has not been definitely established in human beings. The information at hand indicates that it is less than two weeks, and probably, in the great majority of cases, between three and eight days.

If the foregoing conception of the disease is correct, it is obvious that effective preventive measures, approaching complete control, are impracticable, because isolation of recognized cases of the disease and restraint upon their immediate associates must fail to prevent the spread of infection by unrecognized cases and carriers.

These difficulties would appear to be inherent in the nature of the disease. Nevertheless, we may hope for the development of more thorough knowledge which will permit of more effective control of the disease than is now practicable. Of first importance is the more general recognition by practitioners of nonparalytic cases through clinical observation and laboratory procedures.

Lumbar puncture has been shown to offer valuable aid in diagnosis, and a more general use of this test is to be encouraged, since it not only facilitates accurate and early diagnosis, but in many cases affords sympathetic relief as a therapeutic procedure. Without undertaking to predict the future progress of research, we may hope for certain possible developments which may afford far more effective control of the disease, with substantial relief from many inconveniences at present inevitable. Among these possibilities we would include: A practical test for the detection of all clinical types and carriers; a simple and reliable test for distinguishing between susceptible and insusceptible persons; and means of conferring artificial immunity against poliomyelitis.

New Publications Received

A Textbook of Practical Therapeutics, with Especial Reference to the Application of Remedial Measures to Disease and Their Employment Upon a Rational Basis. By Hobart Amory Hare, M. D., B. Sc., Professor of Therapeutics, Materia Medica, and Diagnosis in the Jefferson Medical College of Philadelphia; Physician to the Jefferson Medical College Hospital; One Time Clinical Professor of Diseases of Children in the University of Pennsylvania. Sixteenth Edition, Enlarged, Thoroughly Revised, and Largely Rewritten. Illustrated with 149 Engravings and 7 Plates. Philadelphia and New York: Lea & Febiger, 1916. Pp. vi-1009. (Price, $4.75 net.)

Studies in Blood Pressure. Physiological and Clinical. By George Oliver, M. D. (Lond.), F. R. C. P. Edited by W. D. Halliburton, M. D., F. R. S. Third Edition. New York: Paul B. Hoeber, 1916. Pp. xxiii-240. (Price $3.)

Physiological Chemistry. A Textbook and Manual for Students. By Albert P. Mathews, Ph. D., Professor of Physiological Chemistry, the University of Chicago. Second Edition. Illustrated. New York: William Wood & Co., 1916. Pp. xv-1040. (Price, $4.25.)

Status of a Red Cross Base Hospital Unit.—The twenty-five Red Cross base hospitals which have been organized or are being organized under the Department of Military Relief of the American Red Cross have a strictly war time purpose and are not generally available for use for civilian relief after disasters other than war, according to a Red Cross circular just issued. It says:

Attention has been invited by the director of a Red Cross Base Hospital Unit to a misconception of the purposes of this military unit, in that a statement has been made that it would be available for purposes of civilian relief in great disasters other than war.

This is an error, as base hospitals are purely military units, organized at the request of the medical departments of the army and navy, and equipped with a view to the needs of the military service only. In both organization and equipment they are too massive and too immobile for civilian relief work. The muster-in pledge contemplates only national service when called into the military service of the United States, and it has been decided by the judge advocate general of the army that the law does not authorize the calling out of these units by the President except in time of war or when war is imminent.

It can be well imagined that in time of great National disaster, such as an earthquake, which involved injuries to large numbers of people, the staff of a base hospital unit might volunteer *os individuols,* and the American Red Cross would not hesitate to use the blankets, surgical dressings, and such other parts of a base hospital equipment as might be suitable for first aid work to relieve an emergency. These supplies, however, would be regarded as a loan, and would be promptly replaced, if possible, from funds contributed to relieve the disaster. There would be no calling out of the unit *as a unit,* under these circumstances, and no compulsion on any member of it to volunteer.

"Vivisectionists' Operations."—After a period of innocuous and gratifying quiescence, the New York Antivivisection Society is making a new bid for public support by providing a series of thrilling exhibitions supposed to show "just how the vivisectionist operates," says the *New York Tribune* for November 1, 1916. Fifty schoolboys and schoolgirls were invited to the first of these entertainments, and as an additional attraction an English actor, who is apparently not indisposed to advertise himself, was engaged to give a little lecture on the subject of experiments on animals and to tell his audience what he thought of the physiologists.

"Vivisection laboratories represent nothing but waste to my mind," said the popular entertainer with impressive gravity. "To my knowledge there has never come any definite benefit as a result of experiments conducted on an animal." And much more to the same effect about his "mind" and his "knowledge," all in the familiar vein.

It is perhaps not surprising that this gifted performer should have accepted the invitation of the amiable ladies of the society. The footlights have an unhappy effect on the minds of solemn folk of limited learning. They are accustomed to the applause of the multitude, and are naturally apt to acquire an inflated idea of their importance, unless happily they chance to be checked by a portion of humor sufficient to enable them to recognize their limitations.

It appears, however, from a sympathetic report in the *Herald* that in order to illustrate his mock demonstration the actor with "several aids" strapped "a struggling dog" to something described as "the vivisectionists' rack of torture," on the pretence of showing "how operations on living animals are performed." There can be no excuse for exhibitions of this kind. It is indeed inconceivable how women who profess to be shocked at the use of "the vivisectionists' rack" in laboratories can countenance its abuse in the bungling hands of a vain player who has neither the education nor the understanding to discuss the matter at all, to say nothing of illustrating it.

In his own field he is clever enough. His business is to amuse idle Broadway, and if he were wise he would stick to it. If, however, the Antivivisection Society must employ actors to amuse their audiences, let the actors be confined to their own proper gifts of gesture and mimicry. Their vaporings can do little harm, but dogs should not be used to provide school children with new thrills.

Harvey as a Prescriber.—In his Harveian Oration, remarks the *Pharmaceutical Journal* for November 4, 1916, delivered at the Royal College of Physicians, on October 18th, Sir Thomas Barlow remarked that Harvey says very little about drugs in his memoirs, and added: "That is not exceptional in physicians who are distinguished as morbid anatomists. One would like to believe that when the apothecaries of the time disparaged his 'bills' (as prescriptions were then called) they may have been too short and too simple to please the apothecaries. There is a nice report on the case of Prince Maurice when Harvey was with the King at Oxford, in which it is stated about Harvey and his colleague, Edmund Smith, that the 'doctors doe resolve to give very little physic, only a regular diett and cordyall antidotes.' It is significantly added that Prince Maurice did well. But I think I have noticed occasionally that when a morbid anatomist ventures into the realm of therapeutics he may show an immense confidence in some particular preparation, and it is not altogether an exceptional incident that in a letter to his friend Hamey, which we possess, concerning the ailment of a poor woman in whom they were both interested, Harvey extolled the therapeutic virtue of the heel bone of the deer. Perhaps he found it a useful way of administering phosphate of lime." It would appear, however, whether he prescribed drugs much or little, that after the fashion of his time he was a sedulous practitioner of phlebotomy for the relief or removal of pain, and that he had a profound faith in it for the treatment of asthma.

Influence of Race Stock.—In an interesting and instructive paper recently presented before the American Association for the Advancement of Science, Louis I. Dublin, Ph. D., demonstrated that in New York city, with the notable exception of the Russian Jews, the death rate of foreigners and their first generation of offspring, was higher than the death rate of natives of native parents. According to the *Weekly Bulletin* of the Department of Health of the City of New York for November 4, 1916, Doctor Dublin also called attention to the fact that the death rate of Italian males from pulmonary tuberculosis is lower in New York State than the same rate for any other nationality, and much lower than that of the Italian females. Of this latter phenomenon no explanation is advanced.

This difference in the Italian male and female death rate from pulmonary tuberculosis, as well as the low combined rate, has been noticed by the health department in the past and was again encountered in studying the mortality of the city by sanitary areas. In Monograph 15, page 24, the department refers to the high mortality of Italians from the respiratory diseases and from all forms of tuberculosis other than pulmonary, and advances the explanation that many Italian males coming to this country are either single or, if married, leave their families at home until they are on their feet financially, therefore many of these unattached males who may succumb to tuberculosis return to Italy. Again, it has been found that many Italian men with families in this country who succumb to tuberculosis return to Italy, taking their families with them or leaving them here; whereas the female Italians coming to this country either have been married in Italy or marry shortly after their arrival in this country, and if taken ill seldom return. This has been verified in a general way by inquiry among Italian steamship agents, Italian physicians, Italian clergymen, etc.

In comparing the mortality of the foreign born and the native born of foreign parents with the native born of native parents, Doctor Dublin omits to mention a very important factor, which no doubt was apparent to him; to wit, that the economic status of the foreign born and of the native born of foreign parents is lower than that of native born of native parents, since the tendency is for each generation to advance socially, intellectually, and financially; the natives, being the third, fourth, fifth, or other generation, have advanced beyond the status of their forebears. Again, the tendency is for foreigners upon their arrival in this country to settle in the cities, consequently the health board feels safe in saying that the majority of foreigners in New York State reside in the cities, and of necessity in the crowded tenement sections, whereas a large percentage of the "native natives" live in rural districts, and those who live in New York city are for the most part more healthfully housed. Again, the occupations of the foreigners and of their first generation of offspring are apt to be less conducive to a low death rate than the occupations of the "native natives."

These facts obviously do not change what Doctor Dublin has pointed out, to wit, that the death rate of many foreign stocks is higher than that of the natives of native parents, but it is not fair to assume that their higher death rate is due entirely to any inherent defects in the stocks.

Collectanea

A Statistical Study of Diphtheria.—The following are some of the main conclusions in a paper by Frederick S. Crum, Ph. D., presented, on October 27th, before the Section in Vital Statistics of the American Public Health Association, in Cincinnati:

1. Comparing the preantitoxin with the antitoxin period it is conservatively estimated that there is at present an annual saving of at least 250,000 lives throughout the world as a result of antitoxin and other improved treatment of diphtheria. This estimate is based upon the official mortality returns of twenty countries for a quarter century period.

2. Notwithstanding the great reduction in the diphtheria death rate, this disease is still responsible for about four per cent. of the total mortality at ages under fifteen years in the combined countries of the world which have reliable death registration.

3. Diphtheria still causes more deaths in the United States than scarlet fever, measles, or whooping cough. Diphtheria therefore remains a distinct menace to childhood, notwithstanding antitoxin, its specific curative agent. The average annual number of deaths from diphtheria and croup in the United States is approximately 17,000, against 10,000 from whooping cough, 9,000 from measles, and 8,000 from scarlet fever.

4. There is positive and overwhelming evidence that the earlier the use of antitoxin, the better are the results and the greater is the chance of recovery. There is almost equally positive evidence that the medical world has as yet taken only partial advantage of one of the greatest discoveries (antitoxin) of modern times in the field of preventive medicine.

5. All races are susceptible to diphtheria, but there is some evidence that the negro and the American Indian are less susceptible than Caucasians, Chinese, Japanese, Hawaiians, Filipinos, or Mexicans.

6. The diphtheria attack and mortality rates are highest in the second, third, and fourth years of life. After the age of five years the death rate falls rapidly, and at the adult ages the death rate is only about one per cent. of the average rate for ages under five years.

7. In the registration area of the United States during the five years, 1910 to 1914, 62.2 per cent. of the deaths from diphtheria and croup occurred at ages under five years; 25.8 per cent. occurred at ages five to nine years; six per cent. occurred at ages ten to fourteen years; and only six per cent. occurred at ages fifteen years and over.

8. Both sexes are about equally affected by diphtheria when all ages are combined. The death rate of males is higher than the death rate of females at ages under five years; the rates are about equal at ages five to nineteen years; and the rate is higher for adult females than for adult males. The higher adult female mortality is probably due mainly to the fact that professional female nurses and mothers perform most of the diphtheria nursing service and are therefore more exposed to diphtheria contagion than are adult males.

9. In the mortality experience of a large insurance company for a two year period, including 3,920 deaths from diphtheria and croup, 2,834, or 72.3 per cent., were complicated with other secondary diseases. The secondary complications most frequently met with were heart diseases, respiratory diseases, scarlet fever, urinary diseases, and measles.

10. Density of population, either directly or indirectly, seems to be an important factor in diphtheria morbidity and mortality in the United States and elsewhere. The diphtheria death rate in the United States is higher in the urban than in the rural areas. The rate is higher in the New England, Middle Atlantic, and east central cities and States than in the far western and southern cities and States.

11. Climatological factors, especially rainfall and temperature, apparently influence the relative epidemicity and virulence of diphtheria, but much more extended investigations are necessary before these factors can be properly appraised.

12. Diphtheria is now probably endemic in every country in the world and pandemic in most. Diphtheria is also epidemic in its spread in practically every locality, but at irregular intervals. In 100 cities of the United States during a period of fifteen years there were one or more deaths every year in all of the cities, with one exception. During this period of fifteen years the annual diphtheria death rates of the 100 cities (1,500 rates) ranged from zero to 173 per 100,000 of population.

13. In the various countries of the world the average annual death rate from diphtheria during the most recent five year period for which the data are available has ranged from 6.8 per 100,000 of population in Chile, and seven in New Zealand and The Netherlands to nineteen in the registration area of the United States, 22.6 in Prussia, 25.9 in Austria, and 40.1 in Serbia.

14. There is no conclusive evidence that diphtheria, as a disease, is decreasing. On the contrary, the weight of evidence is favorable to the view that it is increasing.

15. The underlying conditions which determine the relative degrees of susceptibility to the Klebs-Löffler bacillus and its varying degrees of virulence are still elusive and more or less doubtful, and for this reason the control of diphtheria will probably continue for many years to be one of the serious and difficult problems of sanitary administration.

Human Diseases Carried by Animals.—The Department of Health of the City of New York has compiled the following list of diseases which are carried by animals:

By the dog: Rabies, foot and mouth disease, helminthiasis (flukes and tapeworms), infantile splenomegaly (from dogs through fleas), trypanosomiasis, mange, fleas and ticks, ringworm, and favus.

By the cow: Tuberculosis, actinomycosis, anthrax, cowpox, tetanus (through vaccine), foot and mouth disease, septic sore throat, rabies, pus infections, Tænia saginata, milk sickness, and paratyphoid fever.

By the horse: Glanders, rabies, tetanus, sporotrichosis, and anaphylaxis (serum disease and odor of horses).

By swine: Trichiniasis, tuberculosis, anthrax, cestodes, and trematodes.

By sheep: Anthrax and tuberculosis.

By goats: Malta fever and tuberculosis.

By the antelope: Sleeping sickness.

By the cat: Rabies, cestodes, trematodes, favus, and ringworm.

By rats: Rat bite fever, bubonic plague (through fleas), and trichinosis (through hog to man).

By ground squirrels: Bubonic plague.

By birds: Psittacosis (from parrot).

By fish: Tapeworms.

By arthropods, chiefly insects. Mosquitoes: Yellow fever, malarial fever, dengue fever, and filariasis. Fleas: Bubonic plague and infantile splenomegaly. Ticks and mites: Rocky Mountain fever, relapsing fever (African), tick fever of Miana, and Japanese blood fever. Lice: Typhus fever and relapsing fever (Spirochæta obermeieri). Bedbugs: Kala azar. Flies: Sandfly fever, sleeping sickness (tsetse fly), typhoid fever, and other infections carried mechanically. Crustaceans (water flea): Guinea worm infection (dracunculosis). Oysters, clams, etc.: Typhoid fever. Snails: Trematode infections (especially bilharziosis).

The Kind of Social Service That Is Not a Mere Fad.—It is now nearly a year since a special kind of social service work was begun at the Occupational Clinic of the Division of Industrial Hygiene of the Health Department of the City of New York. This work was largely modeled to conform to the plan of social service followed at the Massachusetts General Hospital, where every patient who is under treatment in the wards or in the outdoor service is assigned to the care of a social service nurse. The latter not only visits the home of the patient in order to ascertain his ability to pay for treatment, but she becomes, if possible, a friend and adviser to the patient and his family on matters of hygiene and sanitation, and helps to secure financial or other aid that may be urgently needed.

There is a growing recognition among physicians and surgeons that domestic conditions in the homes of patients may cause worry or otherwise militate against the success of therapeutic measures, says the *Weekly Bulletin* of the department for October 7, 1916. Likewise, it is of value to know of occupational influences that may directly or indirectly be connected with the patient's illness and which when discovered may form the basis for correct diagnosis and treatment. In many other ways both patient and physician are benefited by this scheme of cooperation with the social service nurses.

At the occupational clinic there are three types of cases in the main which are assigned to the social service nurse for care or investigation:

First: Those who upon examination at the clinic are found to be suffering from a pathological condition which demands treatment in order that grave consequences may be forestalled. In all such cases the nurse makes an effort to induce the patient to consult his private physician, or if means for the purpose are lacking she refers him to a hospital or dispensary. Subsequently she makes one visit to secure the patient's compliance with instructions.

Second: The unemployed are referred to the social service nurse and she makes efforts to secure employment for them.

Third: Those who are engaged at work which is seriously affecting their health are referred to her. Printers, for instance, who are found to be suffering from the effects of exposure to lead and turpentine, are urged to seek a new trade. The city employment bureau and certain private corporations have greatly aided us in this respect.

It is needless to say that no medical treatment is given at the occupational clinic, where work is confined to the discovery of pathological conditions and to giving advice on hygiene and in the prevention of disease.

All who recognize that the scope of preventive medicine has quite properly been greatly enlarged, so far as health officers and physicians as a class are concerned, will readily see that the Division of Industrial Hygiene, which examined a total of 38,959 patients during the first year of its existence, has large opportunities in this field. Of the total number examined by the medical staff of the occupational clinic, 11,487, or slightly more than twenty-nine per cent., were found to present some pathological condition.

Health Conditions in the Philippines.—The report of the Philippine Health Service for the first quarter of 1916, made by Dr. John D. Long, director of health to the Secretary of the Interior, is exceptionally satisfactory. The number of deaths were seven less than occurred during a similar period of last year. In the city of Manila, which has a population of approximately 280,000, the death rate among Americans was 5.86, Filipinos, 28.98; Spaniards, 7.28; other Europeans, 3.33; Chinese, 13.25; all others, 4.19; the average annual death rate being 26.85. This is scarcely more than the average mortality among the colored population of the registration area of the United States, and the mortality among whites is about one half that of the whites of the same registration area. Only one case of smallpox occurred, the first case in the city of Manila since 1908. There were twenty-four cases of varioloid with no death, and fifteen cases of varicella with no death, twenty-four cases of cholera with eleven deaths, and no case of bubonic plague. A total of 25,337 rats was caught in the city of Manila, all of which were found negative for plague. There were seventy cases of measles with two deaths, forty-four cases of diphtheria with six deaths, two cases of cerebrospinal meningitis in which one death occurred, and twenty-four cases and eleven deaths from cholera. In occidental negroes there were twenty-one cases of cholera with eight deaths, and in Batangas there were eighteen cases with ten deaths. During the quarter 38,881 persons were vaccinated against smallpox in Manila, and 151,566 in the Provinces. Of the total number of deaths in the quarter over one half were among children under two years of age. The chief causes of death were tuberculosis, 329, beriberi 193, bronchitis 212, pneumonia 88, and diarrhea and enteritis 112. Additional measures have been taken to promote public health through conferences of district health officers with physicians and pharmacists by appointing a committee to study quarantinable diseases and the duration of quarantine for each disease. Preparation of programs for examination for entrance to and promotion in the Philippine Health Service, hospitalization of cases of measles and smallpox, appointments to sanitary districts, appointing a committee to devise a systematic plan for the extension of the work of the Gota de Leche (milk supply) institution to the provinces, extension of requirements regarding registration of infant mortality and appointment of two committees for the investigation of factory hygiene and school hygiene.

Periodical Examination of Health Department Employees.—There is no phase of public health work, remarks the *Weekly Bulletin* for December 9, 1916, which transcends in value the periodical medical examination. With the great and rapidly growing interest in public health questions this medical attention and medical supervision of employees is becoming an accepted procedure—a matter of course. For the past two years every employee of the department of health has been obliged to meet this requirement of an annual medical examination, in addition to the one received on entrance to the department service.

With the older employees this periodical test is optional, but as the antagonism first manifested toward this innovation has largely disappeared, the majority of both sexes have been examined and some, more enlightened than the others, have requested an examination at short intervals, where the findings have disclosed conditions not entirely satisfactory to the individual.

Up to June 29, 1916, 2,104 employees had been examined, but in order to retain a convenient starting point for future investigations, only the first 2,000 were included in the statistical records. Of the number mentioned, 1,325 were women and 779 were men.

During the past year nearly 1,000 reexaminations have been made, and of these 194 are men and 737 are women. Each case record receives a number, for no names are allowed to appear on the card, and the records, when completed at the end of the day's work, are placed in a special cabinet and kept under lock and key in the office of the deputy commissioner. Male employees are examined by a male physician and female employees by a female physician. The physical record is not allowed to influence in any way the efficiency rating of the employee.

On reexamination about 10 per cent. of the persons examined showed very decided improvement over their former physical condition; some had gained in weight; some, after much effort, had lost weight; certain impairments had received treatment with resulting gain to the patient. Many, when originally examined, had shown no abnormality so that but little change was to be expected.

Every employee, when absent from duty on account of illness, should be reexamined on return to duty. If absences are frequent a reexamination should be made every three months, with a view to determining the cause of disability. Those who are below normal when first examined should be examined in six months' time.

Any employee desiring special medical advice should be made to feel that this is gladly given—that the object of the welfare division is to help keep the employees well and that these medical attentions are not in any sense a philanthropy but a very decided economy to the health department as well as to the taxpayer.

When any particular kind of work is found to have an injurious effect upon the health of the employee, a change to some other kind of employment should be made.

Trinitrotoluene Poisoning.—According to the *Pharmaceutical Journal* (London), for October 18, 1916, in the House of Commons recently, W. C. Anderson asked the Home Secretary whether he was aware that of the 472 cases of industrial poisoning reported during the nine months ended September, 1916, 120 occurred from toxic jaundice, and that of sixty-two deaths thirty-three were attributable to this cause, and how many of these cases were due to poisoning from trinitrotoluene? Mr. Brace replied that the figures were correctly given. The number of these cases due to such poisoning was ninety-five, and the number of deaths twenty-eight. Every possible step is being taken by the department, in concert with the Ministry of Munitions, to investigate and deal with this disease.

Formes Cliniques des Lésions des Nerfs. Par Mme. ATHANASSIO-BENISTY, Interne des Hôpitaux de Paris (Salpêtrière). Préface du Professeur PIERRE MARIE, Membre de l'Académie de Médecine. Avec 81 figures dans le texte et 7 planches hors texte en noir et en couleurs. Paris: Masson et Cie, 1916. Pp. 234.

Bref och Skrifvelser. Af och till Carl von Linné. Andra Afdelningen Utländska Brefväxlingen. Del 1. Andanson-Brünnich. Utgifven och med upplysande Noter Försedd af J. M. HULTH. Upsula: Akademiska Bokhandeln; Berlin: R. Friedländer & Son, 1916. Pp. 429.

La Dermatologie en Clientèle. "L'indispensable en Dermatologie Comment Guérir?" Bibliothèque des Praticiens. Par. H. GOUGEROT, Professeur agrégé à la Faculté de Médecine de Paris; 114 figures en noir en 32 planches; 40 figures en couleurs en 16 planches. Paris: A. Maloine et Fils, 1917. Pp. 764.

The Institutional Care of the Insane in the United States and Canada. By HENRY M. HURD, WILLIAM F. DREWRY, RICHARD DEWEY, CHARLES W. PILGRIM, G. ALDER BLUMER, and T. J. W. BURGESS. Edited by HENRY M. HURD, M. D., LL. D., Emeritus Professor of Psychiatry, the John Hopkins University; formerly Medical Superintendent of the Pontiac State Hospital; Secretary, The John Hopkins Hospital. Volume III, illustrated. Baltimore, Md.: The Johns Hopkins Press, 1916. Pp. 872.

La Clinica Obstétrica y Ginecológical del Hospital Alvear, en el ano 1916. Par URALDO FERNANDEZ y TORIBIO J. PICCARDO. Pp. 168.

Report of the Philippine Health Service. For the fiscal year from January 1 to December 31, 1915. J. D. LONG, M. D., Director of Health. Manila Bureau of Printing, 1916. Pp. 163.

Geschichte der Augenheilkunde. Von DR. J. HIRSCHBERG, Professor in Berlin. Drittes Buch, Dreizehnter Abschnitt. Die Augenärtzte der Schweiz, 1800 bis 1875. Mit 5 Figuren im Text. (Handbuch der gesamten Augenheilkunde, 2. Aufl. XVI. Band, VII.) Leipzig: Wilhelm Engelmann, 1916. Pp. 273.

Proceedings of the American Medico-Psychological Association; at the Seventy-first annual meeting held at Old Point Comfort, Va., May 11-14, 1915. Pp. 387.

Collectanea

Shell Shock is one of the baffling maladies resulting from the terrific nervous strain of the present war. Revolting sights and deeds, the continued noise and strain, the combating of fear, and the additional effect of physical injury and suffering are some of the exciting factors. The underlying cause for this condition is thought to be nervous instability resulting in psychic traumas, and not physical factors. In connection herewith the role of the internal secretions may throw some interesting light on the origin and treatment of the symptoms.

It is stated that the excessive strain causes adrenal insufficiency, which aggravates the nervous depression and thus is a contributing factor to war neurasthenia. Henry R. Harrower (*Prescriber*, October, 1916) calls attention to this relationship of the internal secretions to shell shock, and states that this subject was recently referred to by Rénon in a paper read before the Société de thérapeutique, Paris, and the symptom complex which he describes as due to *l'angoisse de guerre* is almost typical of dyshormonism, and especially that form in which hypadrenia is well marked. Rénon finds that a neuropathic or arthropathic physical substratum is common in patients subject to the more marked effects of "war shock," and that the use of alcohol is a pronounced predisposing factor.

Among the usual symptoms enumerated by Rénon as being due to this "war neurasthenia" are several which can be quickly connected with the endocrinous organs. A progressive loss of weight is the rule—the glands of internal secretion control both nutrition and growth; the temperament is changed and the disposition becomes uncertain—mental instability and activity are commonly connected with ductless gland dyscrasias; arterial tension is reduced—common both in pluriglandular insufficiency and in hypadrenia; dermography is reported to be nearly always present—one of the typical manifestations of severe adrenal depletion is the dermographic sign first mentioned by Sergent, and called by him *la ligne blanche surrénale*. I cannot but believe that the most constant single factor, and one that is quite susceptible to treatment, in "shell shock" or "war neurasthenia," is pluriglandular insufficiency. From what has preceded it will appear that the adrenal medication may be helpful in cases of shell shock or neurasthenia; and doubtless it is, especially if used in the manner suggested by Williams, i. e., desiccated adrenal gland by mouth. Sergent has been using this form of treatment in France, and finds it of exceptional value in the severe cases where the signs of acute adrenal exhaustion are elicited. Here hypodermic injections of adrenaline solution, from 15 to as high as 30 minims at suitable intervals, have undoubtedly saved life.

In the course of the discussion on Corbett's paper, one physician asked why, if these symptoms are due to adrenal insufficiency, cannot they be relieved by the administration of adrenaline. In his reply Corbett said he did not think that adrenaline, administered artificially, was the antidote for shock, because the amounts of adrenaline normally in the blood are exceedingly small, and if an attempt were made to maintain the blood pressure by forcing adrenaline, continued larger doses would have to be used to maintain the results. Such continued and increasing doses would have a deleterious effect upon the bloodvessels, and might increase the concentration of the blood, adding this factor to the shock. I am not sure about this effect of adrenaline on the vessels, but I do know that pituitary preparations are much more effective than adrenaline in the immediate treatment of shock and collapse, their influence is more prolonged, untoward by effects, as rigors, coldness, palpitation, etc., are less likely to follow, and the general influence upon other functions, as diuresis, intestinal peristalsis, etc., are both salutary and desirable Hence recourse to pituitary preparations is now almost the rule in the immediate treatment of shock, though there are undoubtedly cases of severe hypadrenia, such as those mentioned by Sergent, in which adrenaline might be used to better advantage.

New Publications Received

The Sexual Disabilities of Man and Their Treatment and Prevention. By ARTHUR COOPER, consulting surgeon to the Westminster General Dispensary, formerly House Surgeon to the Male Lock Hospital, London. Third Edition, revised and enlarged. New York: Paul B. Hoeber, 1916. Pp. 227. (Price, $2.50.)

The Healthy Marriage. A Medical and Psychological Guide for Wives. By G. T. WRENCH, M. D. B. S. (London). Past assistant-Master of the Rotunda Hospital, Dublin. Second Edition. New York: Paul B. Hoeber, 1916. Pp. 299. (Price, $1.50.)

The Mentally Defective Child. Written specially for school teachers and others interested in the educational treatment and aftercare of mentally defective school children By MEREDITH YOUNG, M. D., D. P. H., D. S. Sc. of Lincoln's Inn, Barrister-at-law. Chief school medical officer, Cheshire Education Committee; Lecturer on School Hygiene, Victoria University of Manchester; Certifying Medical Officer to the Local Authority (Mental Deficiency act) for the County of Cheshire etc. With illustrations. New York: Paul B. Hoeber, 1916. Pp. 140. (Price, $1.50.)

Water Supply, Considered Principally from a Sanitary Standpoint. By WILLIAM P. MASON, Professor of Chemistry, Rensselaer Polytechnic Institute. Member of the American Philosophical Society, the American Chemical Society, the American Society of Civil Engineers, etc. Fourth Edition, rewritten. First thousand. New York: John Wiley & Sons, Inc.; London: Chapman & Hall, Limited. 1916. Pp. 528. (Price, $3.75 net.)

A Test Book of Histology. By FREDERICK R. BAILEY, A. M., M. D. Fifth Revised Edition. Profusely illustrated. New York: William Wood & Co., 1916. Pp. 652. (Price, $3.75 net.)

Recollections of an Alienist. Personal and Professional. By ALLAN MCLANE HAMILTON, M. D., LL. D., F. R. S. (Edinburgh). With original illustrations, photographs and facsimiles. New York: George H. Doran Company. Pp. 416. (Price, $3.50.)

The Practice of Urology. A Surgical Treatise on Genito-Urinary Diseases, Including Syphilis. By CHARLES H. CHETWOOD, M. C., LL. D., F. A. C. S. Professor of Genito-Urinary Surgery, New York Polyclinic; Visiting Surgeon to Bellevue Hospital; Special Consulting Surgeon to Knickerbocker Hospital. Profusely illustrated. Second Edition. New York: William Wood & Co., 1916. Pp. 825. (Price, $5.50 net.)
